Q. North, East, and West. Would the climate have any special effect on the colored man in the far North? Can he endure the northern climate as well as the white man?—A. The mortality immediately after the war among those that went North was very great. It is diminishing constantly. Their children are not affected by it. I was over in Canada in the summer time and also in December—in Halifax, Nova Scotia, and St. Johns—and never heard of pulmonary troubles. They went from North Carolina, largely, soon after the war. And I find a great many of them in Massachusetts and in Maine—healthy, strong apparently as the whites. But you take a grown colored man, past the middle age, reared in the South, and carry him North and he will, in all probability, contract some pulmonary trouble, though the younger class become acclimated. I was in Minnesota last spring, and in the intervening country up by way of Chicago, and I found out there some very thrifty, healthy colored people—strong, robust, with no indications of any pulmonary trouble.

Q. You do not find much effect of their inheriting these pulmonary troubles in the North?—A. No. True, it is an inheritable disease, but where it is contracted by reason of a change of climate by the adult, the child, usually born prior to that time, will not have it, because the germ did not exist in the parent at the time of the birth of the child, but was contracted afterwards.

Q. You do not find the disease of consumption following the colored more than the white in the North?—A. Except when the transfer is made when they have passed well along in life.

Q. Can you suggest any amendment to the landlord-and-tenant act which will make the condition of the tenant farmers better, or enable them to improve it,

without extending immunity for crime—that is, theft and embezzlement?—A. As I stated a while ago, in my opinion the abolition of the homestead law in North Carolina would tend to better their condition along the line of your inquiry.

Q. Are there not advantages in the law which you would desire to preserve?—A. Decidedly so, if it were possible.

Q. Could you not?—A. Unfortunately we have over 2 white men in our State to every colored man—2½ white to every colored man, woman, and child.

Q. (By Mr. KENNEDY.) If you were to repeal the statutory law on that subject, would not, as has been already suggested, the common law thoroughly cover the case?—A. Not all, no. A great many are new statutes. Most of our common law we got from England. It is not of our own creation, notwithstanding it may date back to a time when the memory of man runneth not to the contrary; it is not common law unless it came over from the English common law.

Q. In a case of this kind, where the owner was to have one-half the crop and the man who was cultivating it was taking from that crop, so that when the time for division came his share would be diminished just so much, would he not be liable under the common law?—A. No; because the crop is attached to the real estate, and real estate can not be stolen. It must be made so by statute, and whenever it comes to legislating it goes on and on and on.

Q. (By Mr. PHILLIPS.) Have you any suggestion for a State law for the benefit of the colored people in your State?—A. A State law? Yes; but wholly without hope.

Q. What would you suggest?—A. I think the landlord and tenant ought to be put on equal footing. I think the law ought to bear equally on all. I do not think the entire advantage ought to be placed in the hands of one to oppress the other without redress to the other. I think there should be some remedial steps, and that should be done without hurting the landlord's rights, but it has not been done. I was 4 years in the legislature myself, 2 in the senate and 2 in the house, when times were better with us than now.

Q. You say it could not be done without hurting the landlord's rights; do you mean that in absolute form?—A. Rather in a restricted form. I believe there could be plenty of laws enacted, if there is a willingness to do it, that will absolutely protect the landlord and at the same time lessen the oppression on the tenant; but there is not a disposition to do it. I am not familiar with the landlord-and-tenant act in other States, but I suppose it is about the same.

Q. Have you anything to suggest in the way of a law that might be of benefit to this commission or to other sections in the way of legislation?—A. I do not think that I have. If it is the desire of this commission I will think over the matter and at some time in the future formulate an answer to you. You understand a man of my race in Congress is necessarily a very busy man. I should not like to give an opinion where I have not an opinion. If it is the desire of the commission, I will at some time subsequently give you a written statement, if you desire it, or verbal, after I have had an opportunity to think it over.

Q. We should be very glad to have you make such a statement as you have designated.—A. I should be glad to do that at a subsequent time. There was one other matter I had in mind to speak of, and that was with reference to the convict system in our Southland. I guess you have had a good deal of testimony on that line.

Q. (By Mr. FARQUHAR.) We should like to hear you.—A. At some other time?

Q. Now, if you have the time.—A. In some of our States, especially the South—and I speak from information obtained not wholly in a second-hand way; I have traveled in some of the States, and in some the convict system was terrible. This homestead law in these Southern States has multiplied crimes. The punishment for the most of these crimes is severe. The result is the penitentiaries are filled with people, and a large number of them are colored people. In Georgia especially the system is said to be a very bad one, but it is not that which I have reference to. It is the free labor that is greatly hurt by the convict labor. In that State the most of the convicts are farmed out. You can farm them out and work them on the turpentine farms. My half-brother lives in Georgia, and I have talked with him about it. In Georgia they farm them out on the turpentine farms, where they scarify the trees and dip and haul and distill, and it is all very largely carried on by the convicts to the exclusion of free labor. They work on farms, on the public roads, on canals, and all classes of labor, where, as you doubtless know, the colored people constitute a large percentage of it. It takes the bread and butter out of their mouths, and they are left without a livelihood. This especially reduces the daily or monthly labor, because these convicts are hired out for a little more than enough to pay the ordinary expense of keeping them in the penitentiary.

Now there is another fact I have had my attention called to which is on the line of the landlord and tenant. A convict, during his stay with his lessee, at some time may have misappropriated a spoon, or a knife, or a frying pan, or something that was given him to eat with or cook with during his stay. At the expiration of the time the lessee says to him: "You have stolen a spoon, or a frying pan; you have misappropriated a tin plate. Now, I do not want to punish you; I do not want to prosecute and have you sent to the penitentiary again. If you will work for me here 12 months longer, I will not punish you." Rather than go to court and take his chances, he works on for another year. I speak of the fact to show the utilization of this serf labor, convict labor, to the exclusion of free labor. With us in North Carolina it has not got to that yet, and I trust will not. We have spent several hundred thousand dollars in the purchase of farms; we have built barracks and dwellings for the officers and guards and so on; we have experimented with it and like the system, and all the able-bodied men, not incarcerated for life, are sent to the farm to work out their sentences on the farm, so the penitentiary is about self-sustaining. Within the walls of the penitentiary, where we can not carry them out under the rules to the farms, we make brick; supply a whole county or community, or half the State with bricks that we make there. All the public buildings of Raleigh are made of public brick. And then we have a shoe factory; and while the convict shoes have been confined to the convict farms, now they are getting into the stores. I believe the interstate-commerce law contemplates the prevention of the importation of convict-made goods from one State to another. I believe in our own State it is a great disadvantage, but I have not a remedy, because these convicts must be cared for and the expense must be paid. But it is hard on a particular class. Here is the laboring class deprived of labor sufficient to pay the entire expense of the convict, while the wealthy people are not taxed at all under our present system. But it is one of the best I know of. In South Carolina, Georgia, and other States it is as I have indicated, where they farm them out.

Q. Is there not a system also by which the convicts of the county can be taken from the city prison—taken out and worked under the law?—A. Yes. A good many have workhouses, and wherever they have, instead of the judge sentencing the culprit to the penitentiary, he will sentence him to the workhouse, and he goes out and works on the farm. They work them on the public roads in Wake County, and they build highways and work them on the streets in Raleigh, to the exclusion of plenty of colored and white laborers who can not get the labor.

Q. (By Mr. KENNEDY.) When they are working on county roads, they are not interfering with free labor to any extent. Do you know of any cases in the South or anywhere else where the work on county roads is paid for?—A. In the county where I live they are paid. The men are hired under an overseer, and he hires them and pays them to do that work.

Q. Country roads?—A. Yes; and that is so in several of the counties in my own district.

Q. (By Mr. PHILLIPS.) How are they guarded and kept?—A. They are kept under a guard. Most of them are regarded as trustees where the term is short. They have two or three guards with guns and they march them to the barracks at night.

Q. Not chained in any way, as a rule—not shackled?—A. Not in North Carolina, as a rule, but in Georgia they are tied together like beasts. I have seen them in Atlanta.

Q. (By Mr. CLARKE.) Do you think the convict systems of these States are so framed and conducted as to make criminals and keep them criminals?—A. I might do them an injustice by answering that in the affirmative. I have a very strong opinion, but possibly have not enough data to answer it in the affirmative. I should prefer not to answer it. I could not conscientiously say no, and I should not like to say yes.

Q. (By Mr. KENNEDY.) I should like to say, as to paying wages for work on county roads, I never heard of it except in building toll roads.—A. That is recent legislation in North Carolina. There was a tax imposed for that purpose, and it is called the road tax, and that road tax is collected and kept separate and apart for each township of the county. Overseers are assigned to the roads, and they are to keep up the roads with so much money, and they go and hire labor where they please. The best system of roads we have ever had was under that plan. The law was modified by the last legislature, and I am not informed exactly as to the present law.

Q. Most of those who are in favor of employing convicts for State use only are, in favor of employing them on the State roads only, because there is little or no

competition with free labor.—A. That would have been of great benefit some time ago.

Q. (By Mr. RATCHFORD.) That is still generally true of the States?—A. I think so; but in Georgia and some of the other States it is not so. They put them on the turpentine farms, in the cotton fields, and everywhere else.

Q. (By Mr. KENNEDY.) Is there much of the turpentine industry in North Carolina now?—A. It is nearly a thing of the past. They have never been worked on the turpentine farms in North Carolina. I spoke of Georgia.

Q. (By Mr. CLARKE.) Would not the employment of convicts in the construction of permanent public roads, better roads than the country has ever had before, make them less competitive with free labor than if they were employed in private industry?—A. The least possible evil is work on the public roads, with reference to competition with free labor.

Q. (By Mr. RATCHFORD.) Measured by results?—A. Measured by results. Is there any further question you gentlemen would like to ask?

Q. You are going to submit a supplementary statement with reference to remedial legislation as between the landlord and tenant?—A. That is the only thing you suggested. If there is anything further you desire to examine me on, I should like to have an opportunity to think of it.

Q. You have not given any testimony with reference to general taxation?—A. No; do you care to examine me on that?

Q. That is a question that has been dealt with by other witnesses from the South, and I should like to hear you on that.—A. Just now?

Q. If it is not imposing on your time.—A. Our taxes in North Carolina—I can not say that they are very high considering all things, and yet in the cities we have to pay a pretty heavy tax. I have never found any fault with the taxes. I have regarded them as a necessity, and if they were high it was a necessary evil; and even with the taxes as they are our schools which have come through taxation are very poor. I can not say that I have anything derogatory to say with reference to taxes in North Carolina. I think they are fair and equitable. We have an income tax there on salaries and wages that some have grumbled about. It hits me and a great many others, but then I think that is nothing more than right. If I get \$10,000 as an income from my property, wages, or profession, or office, I do not think I should be exempt simply because that is not a vested property right—that I should be exempt, and that it should come out of some poor fellow that has only \$150 worth of property. I think, being able to do it, that I should be compelled to pay a portion of the taxes. I have got it, as a rule, not always through my own labor, but through the ability to manipulate some other man's earnings, and I should be forced to pay that tax.

Q. (By Mr. KENNEDY.) Does the State tax your Congressional salary?—A. Yes; I have to pay taxes on about \$5,000 a year; there is only \$5,000 a year exempt.

Q. (By Mr. PHILLIPS.) Do you think the agricultural industry pays too large a per cent in proportion to other property, or is it comparatively equal?—A. I think the taxation in North Carolina is pretty well equalized. I think our legislators have been, in the main, wise. I love North Carolina. I am not sufficiently informed as to other States to give you an intelligent answer.

Q. Will you deal later in your supplementary testimony with the question of education—the school question?—A. Limitedly, yes, I expect.

As to the question of interest. The maximum per cent of interest that can be charged in North Carolina, as you know, is 6 per cent. Until lately, by contract it might be made 8 per cent. In mortgages, instruments, liens of that kind, notes were always made by agreement 8 per cent—between grantor and grantee, whatever the instrument may be. The recent legislature has made it 6 per cent in all cases. That has kept a great deal of money out of the State. We are not a wealthy people, nor are we paupers. There is a normal condition existing in North Carolina. There are a few extremely wealthy people, and it is a rare thing to see a beggar. Nevertheless, there are a great many poor people there and as a result there is a great deal of surplus money, and a great deal of the floating money has been obtained without the State. This legislation, making the maximum interest that could be charged 6 per cent, has tended to keep a great deal of surplus money that has been thrown into our State flowing out of the State. You do not mind putting money out in your own State, where you know the men and securities, at 4 per cent; but when you send it down to North Carolina you want a larger per cent, as the risk is greater. The result is, a great deal of the money which would have been brought into this State by building and loan associations and otherwise has been kept out. Building and loan associations have been frequently driven out of the State. My opinion is that, while it may have helped some, it has hurt a great many. I do not think the legislation was wise.

Q. You spoke of interest; do you mean simply statutory interest, or the interest charged between man and man in their dealing?—A. In some cases 20 per cent is charged, as in these store accounts; 50 per cent in many instances.

Q. (By Mr. RATCHFORD.) There is no trouble in borrowing money on real estate security, is there?—A. Very few care to take real estate security. They prefer personal indorsement; but if they take real estate security, they want the personal indorsement of some man whose solvency is beyond doubt.

Q. Is it not sometimes secured by the crops in the ground?—A. Very small quantities. That is along the croppers' lien business, but as a rule that is not cash. There are very few tenants who get cash on a croppers' lien from the landlord or the storekeeper. I am the tenant, and you are the land owner [indicating]. You make your contract here with the storekeeper to get certain things, and you sell to me whatever you please. There is very little cash business. If I want something at the store I give security, and I go to the store and get whatever I want, and it is charged to the landlord and he puts it up against me.

Q. (By Mr. CLARKE.) When you state 20 to 50 per cent is charged in a store, that is not charged as interest, but as a profit on goods, is it not?—A. Yes; almost no money passes between.

Q. (By Mr. RATCHFORD.) Is that scrip you speak of negotiable?—A. It was until recently. We passed an act there prohibiting negotiations of the scrip of that character.

Q. Do you regard stores that you speak of, which I suppose may properly be called truck stores, as an evil to the common people?—A. They are absolutely necessary, stores of some kind.

Q. As conducted at present, do you regard them as evil?—A. If we had any other place where we could get our supplies; yes, sir; but usually it is getting them there or not at all.

Q. (By Mr. CLARKE.) Has the destruction of the negotiability of that scrip driven the scrip out of existence?—A. No, sir; it is largely the practice now, but it is unlawful.

Q. (By Mr. RATCHFORD.) It is very difficult to make a law that will reach it, is it not?—A. Yes.

(Testimony closed.)

CHARLOTTE, N. C., March 13, 1900.

TESTIMONY OF MR. WILLIAM A. GRAHAM,

Farmer, Machpelah, N. C.

The subcommission of the United States Industrial Commission met in the rooms of the Southern Manufacturers' Club at 10.40 a. m., Mr. E. A. Smyth presiding. Mr. William A. Graham, farmer, Machpelah, N. C., was introduced as a witness at 4.45 p. m., and, being duly sworn, testified as follows:

Q. (By Mr. SMYTH.) Will you give your name?—A. William A. Graham.

Q. Where do you live?—A. I live at Machpelah, Lincoln County, N. C.

Q. What is your occupation?—A. I am a farmer, sir.

Q. Will you tell us something about the conditions of farm labor?—A. I will state first that I am a member of the board of agriculture of the State.

Q. (By Mr. RATCHFORD.) State board?—A. Yes; and have served in the State Senate, and also president of the Farmers' Alliance of the State at the present time.

Q. (By Mr. SMYTH.) Now, make your statement in your own way. We should like to know something about the general condition of labor, both white and colored.

The WITNESS. Agriculture has not been remunerative with us. We have been keeping away from it on account of the low prices of our products, and it has not given us any money for several years past. The price of cotton is now at a very good figure, but unfortunately the farmers have nearly all sold, having sold out at the close of the crop. The farmers of our country here have come for the last few years to farm a good deal better; looking forward to permanent improvement for a good many years. There was no permanent improvement of the lands. But a few years ago they turned their attention to the pea as a renovator of the land, and large areas were sown in pease, not only for the forage they would yield, but for the improvement of the land for the cotton crop. We found by using the pea we reduced the amount of fertilizer we had to have next year. It will supply

the ammonia, and then it is a simple thing to supply the phosphoric acid and potash. There are sections of our State which have nearly altogether what we term croppers and renters. A cropper is a farmer who furnishes his labor, and the landlord does the rest; he furnishes the land and utensils. Then the landlord pays for the fertilizers which he gets, in proportion to his part of the crop, and the cropper his portion: With us the cropper receives from one-third to a half; sometimes two-fifths. That is the only way that we can farm in this country. A man who attempts to farm for wages goes into bankruptcy, sir. You may not see very well how that is. Cotton now is selling for 10 cents. If we should calculate our crop at 10 cents, and make our engagements with our laborers at that rate, and then it went to 6 or 5 cents, you can see just exactly what would happen. I speak for western North Carolina; I have not been in the eastern part, but I think this system prevails generally all over the State. Then there is another system, the tenant or renter.

Q. (By Mr. RATCHFORD.) Describe that system.—A. The renter furnishes the stock, and the landlord furnishes the land and the house in which he lives, and he pays him one-third of the grain, and one-fourth of the cotton in some places and in others a greater or less part of the crop.

Q. (By Mr. SMYTH.) In furnishing the land and house, that always includes the wood, does it not?—A. Yes; and fully an acre for garden purposes.

Q. (By Mr. RATCHFORD.) The wood and fuel is supplied?—A. Yes.

Q. (By Mr. SMYTH.) Which, of course, is a very important matter to a household?—A. There is no limit to the fuel, except to require him to cut the dead and damaged trees. They do not want them to cut the good timber for fuel.

Q. Now, are most of the croppers or renters in your section black or white?—A. In my county, sir, four-fifths of our population are white. In my end the negroes are about one-third, and at the other end of the county there are only two colored votes at one precinct. There is no difference in the prices paid; the colored cropper gets just the same proportion as the white man, and so does the colored renter. Some few negroes rent land.

Q. Do you find that the colored men make as good renters as the white men?—A. A good white man is better than a good negro, but a good negro is much better than a mean white man. If you can get an intelligent white man whom you can depend on, he is the best class of labor, but if you get an unreliable fellow, the negro is better.

Q. (By Mr. RATCHFORD.) Is it true that a larger percentage of the negroes are indolent than of the white men?—A. Yes.

Q. Farm laborers?—A. Yes; I think that is true; he is more usually satisfied when he is indolent.

Q. (By Mr. SMYTH.) Are they more unreliable in regard to a trust?—A. Well, I do not know. Some of our negroes are as reliable as anybody, but the larger proportion of negroes are more unreliable than white men. I do not think that the negro as a farmer has improved in the last 40 years, since freedom. If you give me one of our old slaves that used to belong to us, who was taught his farming under an overseer or owner, he is a better farmer to-day than the new crop. However, there are some exceptions.

Q. (By Mr. RATCHFORD.) Farmers have advanced in other lines?—A. Yes; they are more intelligent and they live better now. When we speak of the condition of the farmers, the demands of the farmer to-day are much greater than they were 30, 40, or 50 years ago. If they had coffee for Sunday or sugar two or three times a week it was all that was expected; the supplies of the family were not as good as they are these days.

Q. I understand you to say that the colored labor, farm labor, has not improved in the last 40 years?—A. I do not think so much as some classes of labor improve in other lines.

Q. (By Mr. SMYTH.) You mean the general laboring class in North Carolina?—A. No; I mean colored labor. Well, I do not know, sir. We had among the slaves blacksmiths and carpenters that were the equals of what we have now.

Q. Is education more in evidence among them now than then? They are improving in that direction?—A. Yes.

Q. (By Mr. C. J. HARRIS.) Do you think the farmers—by that I mean men who own the land, men who follow the business of farming—as a class have improved much in their methods since the war?—A. Well, yes, as a class they have. We had among us farmers before who were exceptionally fine farmers. I think now as a class they have improved, yes.

Q. (By Mr. SMYTH.) Do you not think the improvement dates back 8 or 10 years to the improvement of the soil?—A. Yes. As to the question of farm labor 40

years ago: Thirty years ago, almost, I think a larger per cent of the young men of this section as they grew up emigrated—went South or West about 1878; from that on, they ceased, and consequently our country has been filled up with laborers, so there is a much larger number engaged in agriculture than were formerly. Now it is very seldom you see a man emigrating. When the Georgia lands (Cherokee Indian) were opened, and after that Mississippi and Louisiana, a great many people of this section of western North Carolina sold their lands and went to these places, and then we had a large number of old fields, abandoned lands.

Q. The cotton mills have drawn very largely on agricultural labor, have they not?—A. They have.

Q. So if he is not satisfied with the present conditions, he has the cotton mills to fall back on?—A. Yes; he not only does that, but a man will buy a piece of land, contract for it, and rent that land to some other man, and he will go to the cotton factory and make the money to pay for it. I know of instances right among my own people. It is not that they prefer factory labor, but it is the long credit on farms, sir. That is where it is; wait until the crop is made before you can get anything, while in the factory every Saturday night you get cash pay.

Q. And that is the practice?—A. Yes; that is one reason.

Q. In other words, it is a rather new thing in Southern life to receive cash payments from week to week?—A. Yes; but the poor returns from the farm and the large families helped to induce moving to factories. A family of 10 to 14 is no unusual thing in this Piedmont section. Where they are only getting from 3 to 5 cents for cotton, it did not yield enough for his board; and such a man would take his family and go to the cotton mills.

Q. (By Mr. C. J. HARRIS.) What are you raising—tobacco?—A. I make tobacco; made a fortune on that. We have cotton, corn, etc.

Q. (By Mr. RATCHFORD.) Do you attribute any part of the general depression to the large care that the average man has on him in the way of a large family?—A. Yes; and more especially to the fact that he can not make enough to support them.

Q. That is generally true of the poor classes, is it not?—A. Yes. This coming to the factories has a bad effect in some instances. It has where the man puts his family in and he spends his time loafing. He is a very trifling citizen. He lives on what they make, and instead of being the mainstay of the family, he stays himself on the family; that is the exception, though.

Q. (By Mr. C. J. HARRIS.) Are you at all familiar with this movement of tobacco growers as against the Tobacco Trust?—A. Yes, sir; the price of tobacco has gone down, I think, if I am not mistaken, over 50 per cent in the last 8 or 10 years, while the crop has decreased. Cotton has gone up because the crop has decreased, but the crop of tobacco decreasing has put the price down in this country.

Q. To what do you attribute that?—A. The combination, the Trust. They agree what they will pay for it, and one will not bid against another.

Q. (By Mr. SMYTH.) A combination of buyers?—A. Yes, sir. When more than one wants it they say, "You take it to-day and I will take it to-morrow; or you buy it and I will take what I want from you."

Q. (By Mr. C. J. HARRIS.) So the tobacco grower really has no idea what he is going to receive for his crop when it is harvested and sent to the warehouse?—A. No, sir.

Q. (By Mr. SMYTH.) And the competition of demand and supply has been eliminated?—A. Yes, sir; entirely. It is agreed that you go to a certain market and all competition on that market is withheld from you.

Q. You think that is established without doubt?—A. I think so from the testimony. You understand what the Association means to do, Mr Harris?

Q. (By Mr. C. J. HARRIS.) Yes, I have followed that.—A. They intend to put the price in their own hands. We say we will fix the price; that they can have our tobacco at a certain price. I do not think there is any doubt but dealing in futures has a very great deal to do with the low prices we get for our products, and it really seems to me that the Government ought to treat that exactly as they did the lottery. These futures should not be allowed to go through the mails. The lottery robs you after you have made your dollar; it does not come in and say you have got to take 60 cents for that dollar, but you make your dollar, and if you are fool enough to put it in here I will get it. The future man robs you of the dollar by giving you 60 cents for it. If you can get Congress to see it in that light and treat it as a lottery that will break it up. If you stop it they will still have it in Liverpool; but so they have got the lottery in Habana and Paris.

Q. Now, if the farmer can hold his cotton crop?—A. I am president of the Cotton Growers' Association, and we are endeavoring to make arrangements to that end.

Q. Is there in the farming community any ready money to enable them to do

that sort of thing?—A. No, sir; there is very little of it. The farmers in our section here, a great many of them, have bought homes in the last 30 years, and consequently they are in debt, and they have to raise cotton for the credit. There is one thing I want to impress upon you: Cotton is the thing to get credit on in this country. Ten acres of cotton will give you more credit than 50 acres of corn.

Q. (By Mr. RATCHFORD.) Is cotton accepted as security before any other crop?—A. Decidedly.

Q. And sometimes accepted as security before land values?—A. Yes, sir; I do not know but it is. If you wanted to run a farm, and came to town here and gave a mortgage on your cotton crop there is no difficulty, but I have seldom known of any taken on the grains. You can always sell cotton. You leave home with a wagon load of cotton and you will go home that night with the money in your pocket; you load up your wagon with wheat or corn and come here with 100 bushels, and I doubt some days whether you could sell it.

Q. Sometimes your farmers find it necessary in buying homes to mortgage their holdings; have they any trouble in raising money on their land?—A. Recently they have had. There has been a scarcity of money in our country. Very few men have money to loan, and the national banks can not loan on land.

Q. What per cent do you pay?—A. Formerly 8 per cent; 6 now. Eight was allowed if specified in the contract, and 6 if no rate was specified.

Q. The law does not preclude the making of special contracts by the parties?—A. Yes, sir. We have the national banking law. We had a law here before that that a man forfeited his whole debt if he charged usury. They passed a law—I forget what the forfeiture was—but that would not apply to national banks. Then we made our law conform to the national banking law, a forfeiture of double the interest charged in excess.

Q. Under the law more than 6 per cent can not be charged without usury?—A. Whatever is charged in excess of 6 per cent, double that amount can be recovered. It may be a little in politics, but here is the trouble with the finances as I see it. A community ought to be able to raise the money it needs on the property of the community. Money is simply the vehicle of commerce furnished by the Government, and there ought to be some plan by which the money needed in the community could be raised on the property of that community. If you give to one community the right to issue money on its property, and refuse it to another, you simply give to the community to which you allow this right the power of taxation on the other to that extent. It may be a small amount, but it is that much. The effect is the same if you limit the right to issue to property held in certain sections.

Q. (By Mr. C. J. HARRIS.) In your experience, are those who mortgage their farms able to pay their interests and eventually the principal in this country?—

A. I can answer from my own experience. I have been an agent for 30 years selling property, and one year with another it pushed them to do it. A man will make a contract to pay out in 8 years, and you frequently have to carry him 10 years.

Q. Do not quite a number of them lose their homes and farms eventually?—

A. I think that public sentiment would condemn that. It has been done only in a few instances. They would have to do it if the men took advantage of what the law would allow them, but public sentiment is against it, and the poor returns from farming do not make the seller anxious to possess the land.

Q. What I was trying to get at is, do they ever get out at the end of 10 years?—

A. Oh yes. I have sold thousands of acres, 3 or 4 thousand acres in the last 15 years, and they have paid out in 10 years. Two men came in and surrendered out of about 40.

Q. (By Mr. RATCHFORD.) You were speaking of the comparatively small difficulty in selling cotton as compared with the other crops. Is the cotton sold usually by the man who raises it to the manufacturer, or is it sold to agents?—A. It is nearly always sold to the manufacturer. I could leave home this morning and have the choice of 32 mills and not travel over 40 miles, and put my horse in my own stable that night.

Q. (By Mr. SMYTH.) Can you telephone and find out what they will offer for cotton?—A. Yes; that is what I do. I telephone, "What is cotton worth to-day?" The last cotton I sold I made a half cent a pound by the use of the telephone.

Q. What is the market here as compared with New York?—A. Nearly always higher. Our market is nearly always higher when cotton is low. We can generally sell here during the first months of the fall; and frequently get a cent higher in Charlotte than in New York.

Q. That is caused by the local mills?—A. Yes.

Q. (By Mr. C. J. HARRIS.) That has been a good thing for the farmer?—A. Yes, sir.

You ask about the benefit of farmer's organizations. The Alliance, in its palmy days, was a great benefit in this State to the farmers. It nearly broke up the lien system. The Alliance would furnish these men who had to have supplies; it would borrow the money and buy the goods and sell to them at cash prices; and flour, which they had to pay about \$4 a 100 for, they could get for less than \$3; molasses and sugar the same way. The Alliance would not register its mortgages, because, while you might lose the debt, you had the criminal penalty on him, and a man could not afford to evade his debt without fear of being punished by the criminal law. Many farmers who could not pay these extra prices got to making money and got on their feet. I do not suppose the mortgaging of crops has even to-day got back to two-thirds what it was formerly.

Q. (By Mr. RATCHFORD.) Was it not of great advantage to the farmers to continue that organization?—A. Yes, sir; unfortunately politics got into it, and that nearly "busted us up." We are still holding on, though, and it will gradually come back. The tobacco men will all come to us. I look for a reorganization with politics eliminated.

Q. (By Mr. C. J. HARRIS.) What is your membership here now?—A. I suppose between 5,000 and 6,000 in the State of North Carolina. They always were irregular, sometimes a difference of 4,000 or 5,000 in a quarter when in full blast. Now there is one thing that you gentlemen can examine into, and that is the advance in the price of fertilizer; that can not be anything but a trust. The raw material is controlled wholly or in part by these companies who make the fertilizer. Take the phosphate rock; take the cotton-seed meal; the potash is imported 12 months ahead from Germany. They made fertilizers last fall and put them on the market at the old price up to the 1st of September. They began to sell at the same price in January, and suddenly they went from 15 to 25 per cent advance. There can not be any excuse for that except the power to do it. You could in your commission summon these witnesses before you and look into that fact. It certainly affects us very much. If we are trying to improve our farms we want to use the fertilizers, which are a great benefit.

Q. Would not the general advance in all values seem to justify an increased price for that product?—A. They are selling us fertilizers at the price of 10 cent cotton, while we may have to pay for it in 5-cent cotton. That is where the trouble comes in. We can not apply it to the cotton already made, but have to pay for it with the cotton next fall.

Q. The men that manufactured these things have to pay more for the wages and for the machinery—perhaps 40 per cent more than they did?—A. There is only one—cotton seed—those that use cotton-seed meal; but in the potash and phosphate and acid there is no reason. There is more phosphoric rock apparent in the world by 50 per cent than was ever known before.

Q. (By Mr. SMYTH.) But has not the farmer got a better price for cotton seed than he did last year?—A. It is 22 cents as against 14 cents last year; but take the acid phosphate, which is simply taken out of the rock.

Q. (By Mr. C. J. HARRIS.) The advance in the price of phosphate rock you think will not warrant it?—A. No, sir. The advance of phosphate rock is as if you owned a farm and a mill and you put up the price of wheat to yourself and the price of flour to me.

Q. (By Mr. SMYTH.) You think these companies own the phosphate rock?—A. Yes, sir.

Q. Are you sure of that?—A. I am on a committee looking into that. We have to make a report next month, and we think we are on the track to show it. There is another thing about it. In Wilmington, which is down on the seacoast, fertilizer is higher than it is 100 miles inland. They have distributed the State and put the prices as they strike competition.

Q. Are there fertilizer works in the State?—A. Yes, sir; here and at Nevassa, Wilmington; then at Raleigh there are phosphate works, and at Winston and Goldsboro. The Acme works at Wilmington are independent. Through the Alliance we endeavor to make arrangements for the whole body. We buy several thousands of tons at a time.

Q. You have no lien law in this State?—A. Yes, sir.

Q. Is it similar to the one in South Carolina?—A. To some extent. The landlord has the first lien, without any writing of any kind, for the supplies which he advances to the tenant, and he has a lien on the crop until all that is due him for rent and supplies is paid.

Q. Have you an agricultural contract law?—A. The bargain is the law. At one time we had a written law. The objection to the written law is that so far as your tenant is concerned it might as well be in Hebrew as in English. What does he know about what he is signing? He is the sufferer. The first thing was

to get a verbal law so that if he did not know a letter he could understand what the contract was. The verbal law is the very thing for the poor uneducated. If you have a written contract, the written contract is the law, but if you have a verbal contract the laborer has his oath as to what it was.

Q. You mean the written contract shows for itself, whereas the verbal contract can be explained?—A. Yes, sir.

Q. (By Mr. RATCHFORD.) Is that equally binding on both parties?—A. Yes, sir.

Q. Can the farmer dismiss the tenant without violation of the law?—A. No, sir.

Q. Can the tenants leave the farmer without a violation of the law?—A. If the tenant leaves, the farmer is in a bad way, but if he has hired him to make a crop and runs him off he can recover his wages out of the landlord because the landlord is worth it.

Q. (By Mr. SMYTH.) You favor the verbal law?—A. Yes; it is the only thing in the world for the ignorant man. He may honestly try to recollect the written contract and may forget what it is, but if you have a verbal contract his word is as good as that of the landlord.

Q. (By Mr. RATCHFORD.) Where the written law is in effect, is it always executed, so far as the signing of the contract is concerned, before the justice of the peace or other officer of the law?—A. It would have to be recorded to be of value.

Q. Is it usually agreed to and signed by both parties without witnesses?—A. They usually have witnesses, but no official witnesses—a neighbor or anybody else. Then it is proved and recorded.

Q. You think a verbal law is still better than that?—A. Decidedly, sir; because you know these verbal contracts are based on the general system, and if you know what wages are paid in the neighborhood, that will help one or the other in his testimony.

Q. Have you any suggestion to make for the improvement of this class of labor?—A. No, sir; we get on pretty peaceably in this State, I think. The only trouble has been the low price which our products have brought. We have all been in the same boat. If it has been a good price, all share the benefit; if it is low, all suffer.

You seem to be specially interested in the schools. In this State we take a census of the school every year. It is the duty of the committee in each school district to do that. So we know in this State how many children there are of each race of school age from 6 to 21 years. Our tax is divided between the two races according to number without regard to race. Sometimes there is a small district with only 25 children; here is another with 150. The larger district had a longer school than the smaller one. Now the educational board makes a special appropriation for the small district and our schools are run on for the same time in every district without regard to number of scholars.

Q. (By Mr. SMYTH.) How long a time?—A. From less than 3 months to over 4 months.

Q. (By Mr. RATCHFORD.) What is the proportion of colored in North Carolina compared with white?—A. I suppose about one-third colored and two-thirds white.

Q. What is the proportion of taxes paid by the two races?—A. My impression is the negroes own \$3,000,000 out of \$200,000,000. So you can see the part the negro pays, except the poll tax, which is the same, and two-thirds of which goes to the school and the other one-third goes to the poorhouses, or county homes as we call them now. You spoke of these 8 and 9 months schools. The laboring people among the farmers can not spare their children for such a time as that. The large families which they raise come in again in this very matter of schools. Before the boys are 21 a great many of them are married, and the girls before they are 18, and instead of staying at home and helping the old man out they have crops of children started of their own loaded on him. That looks as if we were going into the funny part of it, but it is the honest truth. Another thing is the price of school books. The State ought to regulate that. I reckon some of you gentlemen are engaged in the Sunday schools. You know what Sunday school literature costs. There you get for 8 cents what in the public schools costs \$1.50. If the Sunday schools can make big money publishing that, why can not it be published for the common schools at the same rate? You take a man that has 6 or 7 children to send to school, and the schoolbooks for the children will cost as much as the shoes.

Q. Do you think the State should publish text-books?—A. It should contract for them, and either furnish them free or at a lower rate.

Q. In other words, at cost?—A. Yes, sir. A few States, California among them, publish their own books. Whether that is advisable or not is a question of economy and cost. Missouri furnishes them by contract. One child has to have

a geography, another a grammar, and so on. I have lived among these people and my daughters have taught in the schools. If he gets the books, he can not get the shoes, and he must have both to go to school. Our schools begin in December and run through the winter. There should be a term in the summer time.

Q. (By Mr. C. J. HARRIS.) Would not the objection be that it would take the child away when you need his services?—A. We "lay by" our crops in July, and from July to the 1st of September there is 8 weeks when they could go.

Q. (By Mr. SMYTH.) They go barefoot in summer?—A. Yes, sir.

Q. (By Mr. RATCHFORD.) You spoke of the inability of the poorer class of people to spare their children for 8 or 9 months in the year for school purposes. Is it not a fact that children between 6 and 12 or 13 years of age are of little service to their parents, and that they constitute a large proportion of the total school population?—A. You see they begin at 6, and that only gives you 2 years until the child is 8, and from 8 up they work right along.

Q. (By Mr. SMYTH.) Work on the farms?—A. Yes, sir; and by the time he is 10 years of age he is as good a plow hand as a man. These are points which it is right hard to get the people to understand.

Q. You say a boy of 10 is a good plow hand?—A. Yes, sir.

Q. And from 8 up they work on the farm?—A. Yes, sir; and they pick cotton from 6 up.

Q. Do girls pick cotton?—A. Yes; and chop cotton, too. That means they use the hoe in cultivating the cotton.

Q. (By Mr. RATCHFORD.) You say it is nothing unusual to see boys plowing at 10 years of age?—A. No, sir; oh, no.

Q. (By Mr. SMYTH.) Is that general in both races—colored and white—working the children as young as that in the fields?—A. Yes, sir.

Q. It is found to be a matter of necessity, is it?—A. Yes, sir; on account of low prices and the families they have to feed.

Q. So 1 child has to pay the penalty for having a good many brothers and sisters?—A. Yes; and then he starts out to having children of his own, instead of helping these brothers and sisters. Now, there is sometimes a good deal of objection to helping in the higher education, especially in the agricultural colleges or university. Here is one thing about that: If you increase the school fund and run on for 9 months, there is certainly one-third of that time that you hire a teacher, and the boys you intend to benefit are in the field working. If you give the higher education, it is true there are fewer to get it, but they are there for it. They will make an effort to feed and clothe themselves and get that benefit.

Q. (By Mr. C. J. HARRIS.) If there is anything now that you think of that you have not referred to, we should be glad to hear you.—A. About the wages of white and colored teachers. There is no distinction; the first grade gets so much, whether white or black, and the second grade the same way. We have no third grade; we have abolished that.

Q. (By Mr. RATCHFORD.) You have no difficulty in getting an ample supply of teachers?—A. No, sir; none at all.

Another thing: When you come to make your appropriation for agricultural and mechanical colleges here in North Carolina, why should it be divided equally in North Carolina between the races? We have twice as many whites as negroes. Even if the negroes were prepared for it, there would be two whites to one negro. I do not want you to take anything away from the negro, but I want to add a little more to the whites. In your own State, South Carolina, where they are nearly two to one, there are more white boys ready to take advantage of it. The teachers employed in these schools are of higher grade than those required in the colored schools, and consequently the same amount of money does not give the same number of teachers in the white as in the colored college.

Q. Do you find as much desire to attend school on the part of the colored as among the whites in this State?—A. The attendance is greater, but I think it is that they just like to get together, like church or anything else. I think more of them will go, but I do not think it is for the education. The negroes rather care for a meeting of any sort. That has more to do with it than the desire for an education. I heard the State superintendent of public instruction say that the rate of taxation on property in 1860 for educational purposes was greater in North Carolina than in Massachusetts. Our public school system has existed since 1840.

While you are looking into the cotton mills—the first cotton mill south of the Potomac River was built up here near Lincolnton, where Mr. Rhyne has a mill, and most of the machinery was made at Lincolnton, in the early part of the century.

(Testimony closed.)

CHARLOTTE, N. C., March 14, 1900.

TESTIMONY OF MR. CHARLES U. SHEPARD AND

Tea planter, Pinchurst, S. C.

The subcommission of the United States Industrial Commission met in the rooms of the Southern Manufacturers' Club at 10 a. m., Mr. Smyth presiding. Mr. Charles U. Shepard was introduced at 11.30 a. m., and, being first duly sworn, testified as follows:

Q. (By Mr. SMYTH.) What is your name?—A. Charles U. Shepard.

Q. Your place of residence?—A. The name of my plantation is Pinchurst, Summerville, S. C.

Q. What is your occupation?—A. I am a tea planter.

(Here the witness submitted samples of his tea and copies of Report of the Department of Agriculture, No. 61, upon the subject of Tea Culture.)

Q. We should be glad to have you give us the history of your business. When did you begin?—A. I began about 10 years ago. I purchased then a portion of the same large plantation which the Department of Agriculture occupied formerly. The Department of Agriculture, under Commissioner Le Duc, had established a tea farm. The first tea plant brought to this country was planted about 100 years ago on the Ashley River, about 15 miles from Charleston, S. C. Then subsequently, in the fifties, a good deal of interest was manifested as to the introduction of the tea plant and the establishment of the tea industry in this country. Mr. Junius Smith, of Greenville, S. C., made some experiments in the fifties, which attracted very considerable attention, and later the United States Government distributed, through the Patent Office, very considerable quantities of tea seed; they also brought over some tea plants from China. These gardens were established just before the breaking out of the civil war, and necessarily, owing to the resulting disturbance, they were either abandoned or neglected. However, it was well established that the tea plant would grow in the Southern States and that good tea might be made therefrom. About 20 years ago there came a Mr. Jackson to this country—John Jackson, from India—and started a tea plantation in Georgia. It attracted the attention of Commissioner Le Duc and he secured Mr. Jackson's services, and from Henry A. Middleton, esq., he secured the gratuitous use of some of this same plantation to which I referred for the establishment of an experimental tea garden, to be used to test the feasibility of establishing an industry in tea in the Southern States. But Mr. Jackson's health, which had been poor from the start, and which had been the cause of his leaving India, broke down completely, and for the lack of an expert and of someone who would devote his entire attention and energy to the promotion of the enterprise, the undertaking was adjudged by Commissioner Loring, who succeeded Le Duc, and by Mr. Saunders, the horticultural expert of the Department of Agriculture, to be more or less a failure, and was abandoned before anything decisive had grown out of the experiment.

So it was that about 10 years ago, knowing more or less about the previous experiments and what had been accomplished, I began my experiments at Pinchurst at my own expense, and up to the past year almost entirely so. During the past year I have received very welcome aid from the Department of Agriculture in the prosecution of my work. I saw from the start what the main difficulties would be. It was not a question of making a few handful of tea, either for the consumption of my household or distribution among my friends or tea brokers. I wished to produce enough tea to test the commercial aspect of the question, to see whether it would prove acceptable to the American trade and the American people would drink it, and, secondly, to get some figures as to the cost of producing that tea. Of course I was aware of the great disparity in the rates of labor in this country and in the tea-producing countries of Asia, but I was not deterred on that account. I felt that by the production of a higher grade of tea the disparity in the labor question might be overcome. But I wished to test the feasibility of selling large quantities of American tea in this country, because I expected that the tea would have a different flavor and a different taste from that made in any other country; and I knew that in the case of Ceylon, when the English tea growers of Ceylon attempted to introduce their teas into the mother country, they were obliged to practically give away one or two crops before they could get the people to drink it; and now the tea business has grown in Ceylon

from less than 200,000 pounds per year 20 years ago to 130,000,000 or 140,000,000 pounds a year at the present time. So I wished to make the experiment on a scale which would be sufficiently large to introduce the tea over the country and get the decision of the people as to its drinking properties. To that end I have planted between 50 and 60 acres of tea, and I am looking forward, when that tea comes to its full bearing, to a production of from 10,000 to 15,000 pounds a year. With that amount I can thoroughly test the acceptability of American tea to the trade of the country.

With regard to the experiment thus far, it is described in the report of the Department of Agriculture which I have the pleasure of submitting to you.

My work was of a tentative character. To that end I operated with all the different tea seed I could procure, either through the trade or through the kind offices of the United States Government—both the Departments of State and of Agriculture. I tested the cultivation of tea under as many different circumstances as possible—on highland and lowland, on sand, clay, and bottom land. It was natural that many of my experiments should prove unsuccessful, but I hoped that out of the many experiments a way might be shown to produce it successfully. I believe I have attained that object by using the character of seed best adapted to the climate; by selecting level rich land, capable of irrigation, but also well drained. Tea may be produced in this country readily at the rate of 400 pounds to the acre. I see no reason why it may not be produced at the rate of 600 or even 800 pounds to the acre. I have succeeded in producing at the rate of 400 pounds to the acre, with a yearly increase of 50 to 75 per cent in the production, and where the point of cessation in the increment would be I am not at present able to state. From my calculations, I think tea, at the present rates, may be produced at a profit of from 10 to 15 cents a pound; so that it should show a handsome profit as a result.

The object that I had in mind in this work, aside from the selfish one of occupation, was to establish a new industry in a country where tens of thousands of people lack employment; where it is very desirable to supply a healthy, easy occupation during the summer months for children and women particularly; also to find some use for the hundreds of thousands of acres of land suitable, as I believe, for the cultivation of tea, and which are now idle.

I am under great obligations to the Government, to Congress, and to the Department of Agriculture for the interest they have taken in my work, and the present agricultural appropriation contains a large sum to be devoted, on the recommendation of the Secretary of Agriculture, to the prosecution of my work. As to the subject of irrigation, we have only about 30 inches of rainfall during the 6 months of the season during which we pluck leaf, and the tea-producing countries have from 50 inches to 150 inches; and I propose applying irrigation and supplying that deficit.

Q. Secretary Wilson visited your farm when in Charleston last summer?—A. Yes, sir; he has shown the liveliest interest in the work, and the President of the United States did me the compliment of referring to it in his message to Congress. The children who pick the tea for me earn 20 to 50 cents a day.

Q. Your labor is all colored?—A. The tea pickers are entirely colored children. I have a school on the premises for the tea pickers, where they receive gratuitous instruction during the winter months. In fact, the school is kept open for 9 months in the year, and during the 6 months in which we pick they supply the requisite labor. No child is allowed to go to the school who will not pick tea at a suitable age, and all the tea pickers must go to the school.

Q. You make no restriction as to the age at which these children work?—A. None at all. Of course I do not regard it as profitable for a child of less than 8 or 9 years to go into the tea field, but the labor is extremely easy. It consists simply in pinching off the leaves we desire to pluck, between the thumb and forefinger, and putting them in a Swiss trout basket suspended at the waist. It is a very easy kind of labor, and the children are very fond of it.

Q. Easier than picking cotton?—A. Very much easier, and they can earn very much more wages than in cotton picking in my region.

Q. (By Mr. C. J. HARRIS.) How does your product compare with the imported teas as to quality? What is the judgment of experts on that?—A. There is a good deal of variation in the estimate of my tea. It is largely a question of taste, and that is chiefly determined by habit. I have brought you samples of my black tea. I also make a green tea. The green tea that I have made has been reported by the experts as inferior to nothing brought to this country. In the first place, it is a natural green tea. It has not been artificially colored, and the taste is different from any of the sorts in the market. So while the experts and those that have resided in China and Japan are enthusiastic concerning it, the

great majority of the people do not like it, just as they do not like the best types of Chinese and Japanese tea. There is very little tea brought to this country that costs more than 20 cents a pound in Japan. There is a great deal of tea grown in the far Orient that costs from \$5 to \$50 a pound in those countries, but that tea would not be liked in this country at all. People would not drink it.

Q. They are not educated up to that?—A. They do not like it. About my black tea—the teas that approach it most nearly command in the New York market from 30 cents to 40 cents, importers' bulk valuation—that would amount to 75 cents and \$1 retail.

Q. (By Mr. RATCHFORD.) Can you meet these prices?—A. As I stated, as an experiment it was necessary to try all possible conditions and all possible sorts; but working on the lines where I have been most successful, I feel every confidence in being able to raise the tea at a cost of less than 40 cents, even in my small way with only 50 or 60 acres; but proceeding on the basis of 200 or 300 acres it would cost very much less, on account of fixed charges, machinery, etc. That tea I have never had any trouble in selling at above 40 cents a pound. I do not carry any tea over from season to season.

Q. You have been able to sell all that you produce?—A. Always, without trouble. I never carry any over into the next year.

Q. (By Mr. C. J. HARRIS.) Did I understand you to say that a rich bottom land was best adapted to tea?—A. Land rich in humus; it must never be peaty nor must it be crayfishy; on the other hand, it must be a light, porous, loamy soil, favorable for the development of the roots of the tea plant. It is a great feeder. There must be an abundant supply of water, and excellent subsoil drainage.

Q. What zone of country would be adapted to tea raising?—A. A very large field in the Southern States. That would depend on the sort of tea that it is decided to cultivate. The sorts of tea from China, Japan, and the Himalayan provinces of India might be cultivated over a very large portion of the southeastern and Gulf regions. The teas from Assam, Ceylon, and other tropical and subtropical climes might be cultivated over a small portion of the country. They will not tolerate frost and ice, and as we well know, there is only a very small part of this country free from the occurrence of cold.

Q. How many years would it require to bring a tea garden into bearing commercially?—A. In 3 or 4 years a tea garden ought to come into remunerative bearing; I do not mean highly profitable, but remunerative; and that would increase from year to year. My best garden of Chinese origin, as you will see from page 11 of the report, increased from 83.8 pounds in 1894 to 185.7 in 1895; then to 215.9, to 247.5, to 307.3, and then to 469.1 pounds in 1899.

Q. (By Mr. RATCHFORD.) Per acre?—A. For two acres. You see the steady increase—as I said before—50 to 75 per cent a year. What is to be the ultimate production when it arrives at its full bearing, its maximum, I can not tell as yet. I have not had the experiment sufficiently long in operation; but I do know that tea is produced in some of the gardens of India and Ceylon at the rate of 800 and 1,000 pounds to the acre. The production in Japan to the bush is only a little over one-half ounce per year of dry tea. In China it is from 1 to 2 ounces. Thus far one field has given me 5½ ounces; so I think the outlook is a favorable one.

Q. How many years will a tea plant bear?—A. There are bushes in Japan that have been plucked continuously for 200 years, and they are said to give the best tea that is produced in Japan.

Q. Have you reason to expect the same results in your country?—A. I presume so; there are in India and Ceylon many successful gardens from 20 to 30 years old. A very important point is this: I begin plucking in April and pluck until the middle of October. I pick the bushes every 10 days during the season, making 20 pluckings of the leaf. If any untoward stretch of bad weather or any accident intervenes to deprive me for a month or two of the picking, my crop is not seriously endangered, because I have 4 or 5 months yet in which to gather it. I grant that the preparation of the field is very expensive, but considering that it is planted for an indefinite future, and that the plucking takes place over half the year, these are advantages that every agriculturist must recognize.

Q. (By Mr. C. J. HARRIS.) Have your plants been killed by severe winter weather?—A. I have been very fortunate in that. Last year we had the greatest cold that we have had in South Carolina for 150 years; whether there was ever any greater cold here we do not know; but the thermometer fell on the 14th of February at my place to a half degree below zero. Had I known 10 years ago that it might fall to that point I should never have planted a tea plant. I should have regarded it as preposterous. My plants were hardly injured, with the exception of two tea gardens that were in a sheltered position and were in a luxuriant condition when the cold struck them. A cousin of the tea plant, the camellia

japonica—it is a cousin of the camellia thea, the tea plant—was in full bloom, and my roses were also in bloom, we had had such a warm winter; and then came this fearful cold.

Q. (By Mr. SMYTH.) How near are you to the coast?—A. Twenty-five miles. The cold struck them when the plants were full of sap, and the result was that they were stricken almost down to the earth. We had, fortunately, a blanket of 5 inches of snow. I was forced, as you see by the illustration, to prune these two fields down to the ground. I had more tender gardens, but they were in more exposed positions, and they had entered upon their period of hibernation. The plants were not filled with sap. They could resist the cold, but these two gardens, in a sheltered position, were not prepared for the cold. However, they have emerged most successfully, and my gardens, including those two, have never looked in such good condition as they do to-day, and I am anticipating this year, instead of making 3,000 pounds of tea, as last year, to make considerably over 5,000 pounds. I was at the Gridiron dinner in Washington—the annual dinner in January—and I met there the Chinese ambassador. He was interested in my work and asked me where I got my Chinese tea seed from. I told him from the Dragon's Pool tea garden near Hang Chow. He manifested the greatest surprise. "Why," said he, "that is one of our most celebrated gardens. That tea is almost entirely consumed by the higher classes at the court. It is very rarely sold and, if sold, it is sold at such a high price that exportation is out of the question. How did you come to get it?" I told him through the kind offices of the United States State Department and the Chinese Government. I asked him to come down and look at it, and promised him that he should see several acres producing more than they did at home. He was very much gratified.

Q. Do you know what the census reports would show as to the consumption of tea in this country?—A. We consume about 80,000,000 to 90,000,000 pounds. The consumption per head here is much less than in Great Britain and the British colonies. They, outside of the Chinese people themselves, are the largest consumers of tea, the consumption ranging from 5 to 7 pounds of tea per head of population per year. In this country it is only about one-third of that. Russia consumes about what we do per head; then there is a fearful drop, the other nations of the world consuming proportionately a small amount of tea.

(Testimony closed.)

ATLANTA, GA., March 19, 1900.

TESTIMONY OF MR. R. J. REDDING,

Director of the Georgia Agricultural Experiment Station, Experiment, Ga.

The subcommission of the United States Industrial Commission met at the Kimball House at 10 a. m., Senator Kyle presiding. Mr. R. J. Redding, director of the Georgia Experiment Station, Experiment, Ga., was introduced as a witness at 11 a. m., and, being duly sworn, testified as follows:

Q. (By Senator KYLE.) Will you state your full name?—A. R. J. Redding.

Q. Address?—A. Experiment, Ga.

Q. And your vocation?—A. I am director of the Georgia Experiment Station.

Q. You came to testify in regard to the agricultural interests of the State?—A. Yes.

Q. You have the topical plan of inquiry sent by the commission, have you not?—A. Yes.

Q. You are conversant with the agricultural interests of the State, generally, I presume?—A. I am pretty well posted in regard to the conditions generally prevailing.

Q. In this State and the South?—A. In this State and the South.

Q. What are the agricultural products of the State of Georgia?—A. Cotton is the leading product, followed by corn, rice, sugar cane, peanuts, potatoes, and fruits.

Q. Your main crop, and what the farmers call the money crop, is cotton?—A. Yes; in this section. Near the coast rice comes in. That is a crop of considerable importance.

Q. For how many years have you been conversant with agricultural conditions of the State?—A. About 45 or 50 years.

Q. Is it your impression that the conditions are improving?—A. I can not say that they are, sir. I think the farmer is about as hard up; a little more so than he was before the war.

think that the account of the advance in price of cotton is that been of any benefit to the farmers?—A. Because most farmers sold their crop before they got much opportunity to sell, and you to say the price of cotton advanced about 4 or 5 months?—A. No; it was.

Q. Before that, for the first time, we had a very low price for cotton?—A. Yes.

Q. (By Senator KYLE.) What were the prices of 1893, 1894, and 1895?—A. Four and one-half and 5 cents.

Q. And 1897 and 1898, was there a rise?—A. As far back as 1893, did you say? I do not remember exactly.

Q. 1893, 1894, and 1895 you say about 4 to 5 cents, and what was it about 1897, 1898, and 1899?—A. It is about 5 cents, $5\frac{1}{2}$ or 6 cents. I am not so much interested in the price of cotton.

Q. This past year the farmer got for his cotton about what?—A. I suppose the farmer would average 7 cents. Some sold before it got to that point and some held on until it got to 8.

Q. What per cent of the farmers are able to hold on, as you say?—A. I do not suppose more than 15 or 20 per cent of them.

Q. What is the reason they can not hold on?—A. They buy their supplies on credit, and they buy their fertilizers on credit, and they incur obligations and make mortgages, and they are obliged to do one of two things, either go to the bank and borrow money or get their supplies from the commission merchants.

Q. Do you think this difficulty is being removed?—A. Yes. There is a disposition on the part of the banks to loan money to the farmers. They have been more liberal in that particular than usually.

Q. Do you think that more farmers are able to hold cotton than formerly?—A. Yes; I think so. That is due to the spirit gotten up among the farmers and which appeared in the co-operation of bankers and business men last fall at a good many meetings over the State. There was a general desire to come together and benefit the farmers.

Q. (By Mr. RATCHFORD.) What interest do the banks usually charge on money loaned in that way?—A. They loan in the city of Griffin at 8 per cent.

Q. On what security?—A. Personal securities and mortgages.

Q. Mortgages on what?—A. On the crop and land and stock particularly.

Q. (By Senator KYLE.) Do you know of this proposition of New York capitalists to establish farmers' warehouses where they could deposit cotton?—A. Yes; I have heard of it, sir.

Q. Do you think that would be of benefit to the farmer?—A. Well, I suppose it would.

Q. (By Mr. SMYTH.) This 8 per cent money was advanced before the crop was planted, was it not?—A. I was speaking of money advances that were given last fall. The farmers had made their arrangements in the spring, maturing in October and November. They wanted to hold longer in anticipation of a rise, which at about that time had been developed. Notwithstanding the estimates made by some parties, the farmers pretty generally felt that there was a short crop and that high prices would prevail, yet they had obligations to meet. That was what I alluded to.

Q. (By Senator KYLE.) As to diversified farming: Do your farmers here generally raise the cereals that are consumed upon the farm?—A. They generally raise part of their supplies. There are very few farmers who would not like to raise a large part of their cereals, their food stuffs for their stock, but a great many of them make short calculations, and they do not make enough—do not plant enough. I think, however, that there has been a great improvement in that respect.

Q. You think they are raising more wheat, corn, oats, and barley?—A. Yes; no doubt of that.

Q. Than they formerly did? I have before me here statistics taken from the Agricultural Department.

Q. (By Representative LIVINGSTON.) Just pardon me a moment. It is true, is it not, that cotton sold at $5\frac{1}{2}$ to 6 and $6\frac{1}{2}$ before the holidays, and about the 1st of January it went up to 7 cents?

The WITNESS. This past year?

Representative LIVINGSTON. Yes.—A. I do not remember exactly the course.

Q. It was not above $7\frac{1}{2}$ during the month of January, was it?—A. No.

Q. During the months of October, November, and December these obligations to the merchants made in the spring all fell due?—A. Yes.

Q. Not over 10, 15, or 20 per cent. in interest on money and held over; then the great bulk of the farmers, I think, sold their cotton from 7 cents down?—A. Yes.

Q. And therefore, you see, they are better off by the advance?—A. Yes.

Q. (By Senator KYLE.) What is the cost of raising cotton?—A. It costs all the way from 3½ to 20 cents. The price for the last 20 years has been about what it sells for. I think for the last 10 years the market price has not averaged much, if any, above the cost of making the crop.

Q. (By Mr. RATCHFORD.) The average cost to-day is 7 cents, you say?—A. I think that is about what it sells for.

Q. There must have been a great loss when cotton was selling at 4, 4½, and 5 cents a pound?—A. Yes; many men used to live by skinning the banks and cutting the negro or the merchant out of what they owed them. I think a great many farmers do not make any money at all on the farm.

Q. Was this system of money loaning and borrowing practiced generally at that time?—A. No, sir; it was buying supplies on credit and paying at the rate of 30, 40, and 50 per cent above cash prices.

Q. And giving security?—A. Giving security.

Q. Were there many cases that came under your notice where a farmer was unable to pay his obligations and lost his product as a result?—A. Not many of very recent years. I have known a good many cases along in the fall of the year, December and January, where a man has been sold out to pay his creditors.

Q. (By Mr. SMYTH.) Have you a large class in this State who rent land?—A. Yes.

Q. Mostly white, or are a great many of them colored?—A. I should say most of them are colored.

Q. Can a colored farmer raise cotton cheaper than a white farmer?—A. A colored farmer can live harder and make a much poorer crop, and even may pay his debts. The white farmer is not willing to live so hard and deprive himself of so many comforts of life. He must make cotton at a less cost or get more for it or he can not live.

Q. Does the colored farmer live in more dilapidated surroundings, therefore?—A. Yes.

Q. Does he not compete with the white farmer right in that way?—A. Yes. I think that is the great trouble with cotton farming in the South. Negroes in the country are willing to live in the most primitive style, living on hog and hominy, and not always enough of that, and living on blackberries and plums. Those men can make cotton at cost and sell it at 7 cents, and it perhaps cost them really more than that, if they would count up as the white man counts up, the cost of labor of the wife and children. They don't count that.

Q. (By Senator KYLE.) Is not that generally true of all farmers? They do not put in any of these expenses?—A. Largely so.

Q. (By Mr. RATCHFORD.) Will the same condition hold good where the black man competes with the white in other departments of labor, where they work for daily wages?—A. That is true, and I think it is true in regard to factories, that if the white people would allow the negro to come in and take their places for half the price, many perhaps would do so.

Q. What has that to do with keeping the wages of white labor down to its present level?—A. I think the wages everywhere, of common physical labor, are down at the point of actual subsistence, and no man rises above that level unless he becomes skilled, unless he displays extraordinary energy and ambition. As a rule labor in this country gets only a bare subsistence.

Q. (By Mr. SMYTH.) Is that not due largely to the present colored labor?

The WITNESS. Does it not tend to lower the standard of wages?

Mr. SMYTH. Yes.

A. There is no doubt that it tends to lower the standard of living.

Q. I meant the standard of wages?—A. I think so.

Q. The negro will work for less?—A. Yes.

Q. As a bricklayer he will work for less than the white labor, will he not?—A. I do not know so much in the mechanical trades. They seem to stand together pretty well, and keep up prices pretty well. For instance, in Griffin, I sometimes employ negro carpenters—no, I never employed carpenters, I employed brick-masons, and I find that I have to pay about as much as for the white man. Then the white man is generally more intelligent, and he can manage better; he knows more. But as to the common bricklayer, the man who just simply works on the wall, puts up bricks, my observation is that the negro if an expert gets about as good wages as the white man.

Q. Does he have the same opportunities as the white man?—A. Yes.

Q. We have had testimony before this commission to the effect that the colored bricklayer may offer himself at a rate of wages ranging from 50 to 75 cents per day less than the white man. Will you state if you find that to be the case in your observation?—A. No, sir; not a skilled mechanic—brickmasons.

Q. You made a remark that the labor stands together. Are they unionized?—

A. I do not know that they are in a small town like Griffin. I never heard of it.

Q. Do you know of any case where the bricklayers, or any other trade, are organized in the city and the organization embrace both races?—A. No, sir. I do not think there is any organization. There may be. If there is I have never heard of it. I have never heard any suggestions made that these are union prices, or anything of that sort. I employed this man, and I paid him \$2.50; and, as I say, that is about the price of a first-class brickmason, whether white or black.

Q. Do you find in the field of common labor that the negro is a drag to white labor?—A. Yes; no doubt about that. We have white men working on the farms. We frequently have applications every day. But when the white men come and are willing to work we have to say: We can not afford to pay you any more, because I can get a negro for 60 cents a day; if you are willing to work at that price the first vacancy we have you can have it. We occasionally put a white man in in that way.

Q. (By Mr. RATCHFORD.) Is 60 cents a day about equal to the average for farming labor throughout the State?—A. It is above the average.

Q. What will the average amount to?—A. For men?

Q. About 50 cents?—A. About 50 cents.

Q. (By Senator KYLE.) Is it not generally true that hired help on the farm are paid so much and board?—A. On the farms we hire at what we call standing wages, that is give them so much and board them; but not universally.

Q. What is that arrangement?—A. I should prefer that some of these practical farmers answer that question.

Q. I was going to ask whether the condition of the farmers can be materially improved by devoting more time to the production of corn, wheat, oats, rye, and barley, and these things that are necessary to sustain life on the farm, both for the people and the animals, and not so much to raising cotton, which, you say, is raised at a loss.—A. That goes without saying; everybody agrees to that.

Q. The statistics of the Agricultural Department say that there is a decrease in the amount of cereals raised in the Southern States. Georgia is an exception. I am glad to say. There is a gain of 6 per cent, I think, in 10 years; in corn an increase of 13 per cent; in wheat it is a gain of 21 per cent. The loss as regards some of those goes to farm animals. There is a general gain, I think, in the State of Georgia, but there is a loss in milch cows and cattle, a general loss in sheep, and to take the Southern States as a whole there is a very decided loss in 10 years in both cereals and farm animals. In other words, it seems that the people are determined to raise cotton because it is a money crop, and sacrifice everything else to that end. Would the condition of the South be very materially improved by adopting the system of diversified farming?—A. Yes; and I give a different definition to diversified farming. I do not think every farmer ought to grow everything he needs, but I think diversified farming should be followed in a neighborhood by a cooperation among farmers themselves. For instance, one man says, I have got good wheat land; I can raise a good deal more wheat than I will have any use for; you have sugar-cane land. Let us all come together now and say that we will supply ourselves with these things. I will furnish wheat for all of you; you furnish sirup for all of us. Another man has got some nice rice land, and he will furnish all the rice we need. I think that is the kind of diversification that ought to be practiced.

Q. I think that is true of all States where they go on diversified farming; it should be the rule.—A. It is not a desirable thing for a man because he wants 50 pounds of rice to have to go to raising rice. There are a few exceptions where a man does not need much of a thing. For instance, for a tobacco smoker, if he grew his own tobacco, because it don't require any manufacture. But rice requires a mill to mill it, and wheat requires a mill to put it into flour, so if I do not want more than 25 bushels of wheat to supply my family I should not find it any advantage to grow wheat.

Q. Suppose a man had a good wheat farm of 200 acres; would he feel justified in putting that all into wheat, and would he feel that he could get a market for the wheat?—A. I would arrange for my market before I grew the wheat. I would not carry my wheat to town and sell for 50 cents a bushels and then have to go to town and pay \$4 a barrel for flour.

Q. And is your State well adapted to the production of these cereals?—A. Yes.
Q. Can they raise good winter wheat?—A. A large part of the State is well adapted to wheat.

Q. And good corn?—A. Yes.

Q. Is there any corn imported into this State from other States North?—A. Yes; more or less corn. I think it is chiefly, though, demanded by city trade. I think the farmers as a rule, when crops are fairly good, make now a very good supply.

Q. Do the farmers generally raise enough corn to supply their trade?—A. I do not say that. I say most of it is for the purpose of supplementing the supply.

Q. And the farmers buy mules from the North for the purpose of raising cotton?—A. Yes.

Q. They do not raise their own mules?—A. Not as a rule.

Q. Could they be raised here on the ground?—A. Just about as cheap as a steer.

Q. Do you have good pastures here in the State?—A. Yes; we have them.

Q. Can not a man have 3 or 4 steers to turn to?—A. Right there he needs cooperation. A man raises a steer, and the butchers here give him 2½ cents a pound and sell it for 4½ to 5 cents and realize 6 or 7 cents for dressed beef. There is need of cooperation and education to show the farmer that he should not sell his products for less than a fair market value.

Q. What is being done to correct this difficulty and improve the condition of the farmer—your farmers' institutes?—A. Nothing is being done except by organized institutions, such as the experiment station, and to some extent other institutions, like the State Agricultural Society, in a desultory way. The State does not recognize the necessity for farmers' institutes.

Q. You have held a few State institutes?—A. Yes; we have held them, but in an irregular way. We have not any funds to pay the expenses of the managers, or to pay the expenses of speakers and instructors from abroad.

Q. What is the particular office of the experiment station?—A. It is for investigation and research primarily. It is not for the purpose of education, except incidentally.

Q. You make a report, don't you, and circulate it among the farmers?—A. We largely illustrate the better methods, and attempt to get the farmers to follow the methods that we find and prove to be the best.

Q. You demonstrate that certain cereals can be grown to advantage in the State of Georgia, and so notify the farmers?—A. I, for instance, convinced the farmers of Georgia that oats ought to be grown for stock food in this country.

Q. Georgia has done well in oats? No, I will not say that; in 1890 Georgia produced 5,455,000 bushels; in the next year 7,009,000; it ran along at 7,000,000 for a few years and dropped back to 5; then ran to 7 again, and in 1899 it produced only 4,000,000, which is less than in 1890?—A. Well, the great frost in February of last year killed out the oats, except where they were planted as the experiment station directed to plant them. This last February frost did not kill our oats. It is the plan of the station to advise farmers. We did not lose any oats last year, notwithstanding the fact that the weather was below zero, and the farmers are catching on to our methods and devices by which they can save themselves from destruction by winter frosts. That has always been the difficulty in the way.

Q. (By Mr. SMYTH.) How is the standard of oats this year?—A. They are very badly affected by frost where they have been sown in the ordinary way.

Q. Much of that land that was in wheat and oats is going to be torn up and sown in cotton?—A. Yes; I am afraid so.

Q. You said that mules come from the North. You mean West—Tennessee and Kentucky?—A. Yes.

Q. Have you any local roller mills in this State at local points to encourage?—A. Yes; we have some up in northwest Georgia, what I call the wheat-growing section of the State, and what is known as the limestone region, which has been considered a very fine wheat section, and farmers have grown it there all the time as a suitable crop and as a market crop.

Q. More attention is paid to that (encouraging farmers to plant wheat and offering a market for it) by establishing the roller flour mills and making wheat a cash product?—A. That is being done more, even in middle Georgia. I think they are trying to start a mill in Macon, and several have started in various places. Quite an interest has been gotten up in wheat in the last 3 years, and the interest largely centers about Macon. One of the Macon papers has taken a very active part in it.

Q. That is in a city. There is no flour mill established at small points like Griffin and places like that?—A. I do not know a single one.

Q. Would not that tend to increase the demand for the local wheat crop?—A.

Doubtless it would, and a great many old-fashioned merchant mills which used to run years ago, apparently idle now, or only grinding corn, could be fixed up for grinding wheat.

Q. (By Senator KYLE.) What about the possibilities of growing fruit in northern Georgia?—A. They are unlimited.

Q. Where do you find a market for your fruits here?—A. All over the North and West—Boston to St. Paul.

Q. Apples mainly and pears?—A. Not apples; very few apples. Apples generally are for local markets. We have no variety of apples that will compete with Northern and Western apples, as a rule.

Q. What per cent of the agricultural class are tenant farmers in Georgia?—A. I do not know, sir. I would refer you to statistics.

Q. What proportion of the farmers are colored and what proportion are white? The WITNESS. Do you mean by "farmers" those who work in the field, who actually labor?

Q. I mean people engaged in agricultural pursuits.—A. I can not say.

Q. (By Mr. SMYTH.) How many classes of labor are employed on the farm?—A. There are a good many laborers—negro laborers—you know, and some negro farmers that do their own work.

Q. They rent land?—A. Yes.

Q. (By Senator KYLE.) Do they rent from the man who owns the farm?—A. They are farmers in that sense; they rent the farm and have their own stock.

Q. You mean to say that the white people generally own the land that they farm?—A. I think they generally do.

Q. The negro generally does not make much, but he is the tenant and rents his land from the white man?—A. There are a great many different ways to employ negroes—cropping and sharing, and hiring for standing wages.

Q. Now, you can give the commission the benefit of your observations along that line, and the method of renting land to tenants?—A. I have not been over the country so as to form an opinion of the merits of the different methods since I was a farmer myself. I tried from the time the negroes were made free after the war to hire for standing wages, and I am satisfied that is the correct way to do it now. I think as a rule those farmers have been most successful who have hired labor for standing wages.

Q. (By Mr. SMYTH.) What do you mean by standing wages?—A. So much a month or year.

Q. You mean money basis?—A. Yes.

Q. Not a share of the crop?—A. No.

Q. (By Mr. RATCHFORD.) How often do they receive wages when they are hired and then found?—A. To some extent in cash, and others are paid in supplies. Some pay at the end of the year. A good, careful, industrious wage laborer will have something coming to him at the end of the year, and a good, honest, upright farmer will see to it that the laborers have something at the end of the year. But in the case of a good many of them who get good wages, the expenses of their family will absorb pretty much all they make.

Q. In the case where a man is employed at standing wages, does the employer furnish the house to live in?—A. As a rule.

Q. And garden patch?—A. Yes.

Q. Free of charge?—A. Yes.

Q. And pays him about 50 cents a day?—A. It is estimated by the year; so much a month, say \$120 to \$125 a year and his rations.

Q. (By Senator KYLE.) And his house rent?—A. Yes.

Q. That means flour and potatoes?—A. No, sir; it means 4 pounds of bacon and a peck of meal a week.

Q. (By Mr. SMYTH.) He gets fuel?—A. Yes.

Q. (By Mr. RATCHFORD.) Is it not difficult for a man to support a large family on those wages?—A. Yes; pretty difficult. A man working only for himself, or for himself, and wife, and no small children, if the wife is willing to work, can lay up something every year. If a man and his wife have 5 or 6 little children, it is just about "tight and toady" to get through to the end of the year, and then they have to work at all seasons, from the chopping of the cotton to the harvesting.

Q. She usually works for the same employer, does she?—A. As a rule, she does. We employ most labor on the farm, and men are the only ones regularly employed; but in the spring of the year, chopping cotton, and in the fall of the year, in gathering cotton women are mainly employed.

Q. (By Senator KYLE.) That is almost entirely colored laborers on the farms?—A. Almost entirely.

Q. Do these laborers look forward to the time when they can own or rent a farm?—A. I do not think they care much about it as a rule; a few of them do. They do not seem to have much ambition. The negro, if he gets enough to eat and coarse clothes to wear, and something to wear on Sunday, is pretty well satisfied.

Q. He has very little ambition with reference to owning a farm of his own?—A. I notice on our farm and the neighboring farms that the negro is pretty well contented if he has plenty to eat and coarse clothes to wear.

Q. Turning to the other class. Is the young man who is brought up on the farm disposed to remain on the farm?—A. No, sir; I think his disposition is to go away; go to the city factory, or machine shop, or store.

Q. The moment they have an opportunity they leave?—A. Yes; they leave if they get an opportunity. They go to town and get more wages than in the country.

Q. What reason do you assign for that?—A. I think because agricultural labor is not well paid. Agriculture at present is not a prosperous business, of course with a number of exceptions. There are a good many farmers who are making good money and are paying their laborers fair wages, but their sons can not always be kept on the farm. A young man comes up and the father is not able to give him a number of acres of land and a couple of mules as he used to do, and he does not like the idea of starting out with nothing, and if he has got a little education he will go to town and hire out at almost anything in the town. He sees more of life.

Q. I bring this up because of the parallel case of the young men on our farms in the Northwest. Many of them are leaving; they want to go to town. Many reasons are given for it, and I can not say whether it is because farming does not pay as well in the long run as some other vocations in town. They are not satisfied to remain on the farm where they get precisely these comforts. Why do they leave the farm?—A. The farm does not give the wages. They do not get returns every week. They can go to town and get employment and are paid off every Saturday night or twice a month. The man has to work and wait until the end of the year in the country, until the crops mature, and in the meantime he has got to have something to live on, and if he does not have credit he has to live very hard indeed to eke through until he can realize on his crops.

Q. We also learned, of course, in our investigation, that where these young men go to factory towns their lot is very hard also. They get their pay, as you say, every week, but at the same time it is a very hard lot that they have to endure. Is there anything in the social conditions of the agricultural life that makes it distasteful to the young man?—A. Largely so. There are scarcely any social opportunities in the country; the roads are bad, the post-offices are some distance off, and the churches are wide apart. There are no electric lights and street railroads, shows and pretty things to see; those are the things that carry them to town more than anything else.

Q. (By Representative LIVINGSTON.) Young boys are not the only ones who go to town, are they?—A. Others love to go up and get pretty things and have frolics. There are a great many things to attract the young man to town. I do not blame them myself. I have been asked the question, "Redding, you have three sons?" "Yes." I suppose they are all farmers? "No." How is that? "They have got a pretty good education, and they can do much better in the city than in the country."

Q. (By Senator KYLE.) Is there a disposition to look down on agriculture as a low vocation?—A. No, sir; I do not think so. There is never any disposition to look down on agriculture in this country. But laboring people always associate the idea of field labor with negro labor, because most of the laborers in the lower part of Georgia and the corresponding parts of South Carolina are negroes, and if a white man went into the field, he would have to work with the negroes; but that is passing away very rapidly.

Q. Is it not true that the comic newspapers of the country rather make little of agriculture as a vocation? When they want a picture of an all-round jay, it is a farmer with hay seed in his hair and that sort of thing. They try to make it appear ridiculous, and the young man gets on to this.—A. They are mighty glad to get the countrymen's money, and they know how to do it, too.

Q. In speaking of opportunities on the farm, are not the opportunities about as good to-day as formerly for owning a farm?—A. I can not say as to that. Under the old régime, when I began to farm, the farmers owned land and the sons worked, and they were given part of the land, or were helped to buy a farm close by; and it was an easy matter for the farmer's son to start out for himself and get a farm. The father would give him a few negroes, according to his ability, and that was the natural sort of thing. When a man got to be 21 or 23 years old he married a farmer's daughter, and was set up on a farm,

Q. The wages out in my country range from \$20 to \$25 a month, and the work is about the same as was performed by the young man a generation ago; lands are cheap in our country, cheap in your country. Here a young man will hire out on a farm for \$25 a month or \$20 a month, the year round, making \$240 a year, and gets his board and everything except his clothing. By being economical he can save \$200 a year, and in the course of several years he can make a payment on a piece of land, and the opportunities for owning that land in a few years after starting out in life are just as good as they were 25 or 30 years ago?—A. The economic changes have not been as great as in the South. What State is that?

Senator KYLE. South Dakota.

A. There is no colored labor there.

Q. (By Senator KYLE.) Your condition down here is peculiar. I want to know the opportunities for a young white man who wishes to own his farm and the equipments necessary to start out in life.—A. They are considered very good by men who come down to us from the Northwest, men accustomed to labor themselves, even men worth \$4,000 or \$5,000. A man of that description in Georgia does not go on the farm. He hires somebody else to do it. A man from the Northwest comes down to do his own work, and he finds the conditions very much more favorable than he would have found them 25 years ago. They are some of our best farmers. Not, perhaps, more successful for the first 2 or 3 years. They have to adapt themselves to our conditions. Their plowing is better; their hoeing is better; they use better tools, and they are good patterns for our farmers to follow after, and some of our farmers have taken heart and have become just as good as they are. There has been considerable improvement in the last 20 years. There are fewer gullies in the State; they are generally filled up, and now people are freely cultivating the land and making fair crops. The general tendency is to the improvement of the farms, and although there is room for improvement yet, it is far better than it was 20 years ago.

Q. How about the value of land?—A. Lands have not moved much in either direction. They have been of slow sale.

Q. Have you many of what are called abandoned farms—worn-out farms?—A. No.

Q. All land is pretty well farmed in Georgia?—A. There are some old farms—farm estates—locked up in some way. I do not know a single place that can be called abandoned.

Q. What can agricultural land be bought for?—A. From \$5 to \$10 an acre.

Q. Does that mean improved farms?—A. Yes.

Q. With farmhouse and barn, orchards, etc.?—A. Yes.

Q. It seems like a good opportunity for a young man who wishes to get hold of a piece of land.—A. Of course near the villages and railroad towns the prices are higher than that—\$20 and \$30—and the conditions are generally better when near town; but I should say a man would have no difficulty in buying a very fair farm with a good house on it, in fine locations, at \$10 an acre, almost anywhere in Georgia; and in some places for much less than that.

Q. (By Representative LIVINGSTON.) What can be done successfully with proper cultivation of the farm? What crops besides cotton, taking the State as a whole?—A. Taking the State as a whole, they can grow everything but coffee; that is the common saying, and I believe it is true.

Q. Can they grow sugar cane successfully?—A. Yes. We can not grow coffee, but we might grow ginger. I do not mean to say we can grow everything profitably, but we can grow everything, more or less.

Q. (By Mr. SMYTH.) Have you ever experimented in tea?—A. Yes, we have a tea farm started in our State.

Q. (By Representative LIVINGSTON.) Do you think the farmers of Georgia would be vastly benefited by diversified farming?—A. Yes.

Q. To the extent at least that they ought to raise home supplies?—A. Yes.

Q. If they did that there would be no trouble in a young man making a good living and money besides on a farm if he stayed there?—A. Well, no trouble other than this condition (I may express some views of my own in this connection). A man who works on the farm can succeed only by producing something. The city man may live mainly by "his wits" without producing anything. The lawyers and doctors, merchants, insurance men, and other professional and business men live largely by "getting the advantage" in trade. They may live by "their wits," in the sense that they do not produce what they gain or do not give value received for what they gather in. But the farmer can not live that way. He can not get much the advantage of his laborers, because they are already at *hardpan*. He can not make much by dealing unfairly with labor.

Q. Do you think the system of education in the South has something to do with

driving the young men away from the farms and into the cities? Do you think they are educated to the farm, or educated away from work? You talk about living by their wits.—A. I think when a young man goes to an agricultural college, for instance, or goes to any other college, he comes to the city and gets some wisdom, and after he sees the railroads, the electric light, enjoys the social functions, and all that sort of thing, the young man dreads, necessarily, work and common clothes and not good style.

Q. Would it help to keep these young people on the farms in the country districts if they had more of the technical education? Would you advise that?—A. That would be helpful, of course. I think it would be very desirable, if a young man goes on a farm, that he know how to do everything on the farm in an expert manner.

Q. Our schools do not teach that at all, do they?—A. No, sir; I do not think they do.

Q. Therefore, when a young man is educated at Athens or Emory or Mercer or any other school in the State, he will learn nothing about farming?—A. Except theory, and not much of that.

Q. Has not that something to do with our young people drifting away from the farms and hunting professions and other business? Their education, they think, fits them to do something, and they have not the education to farm?—A. I have no doubt that has something to do with it, but I think a man quits farming because it does not promise an easy living, and goes to the city professions, and that includes all professions, where it seems to promise an easy living.

Q. (By Senator KYLE.) But suppose the young white farmer has worked hard for years and denied himself the social functions you speak about and now owns his farm, and in his old days is able to sit in his own house and on his own grounds and enjoy probably some of the comforts in his declining years, whereas the party who goes to town and works in the factory does not?—A. I remarked it seems to him that way.

Q. But in your judgment is not the white man who starts out in the agricultural vocation really better off in the end?—A. I should rather think so in the long run, unless he goes to town well equipped. My boys, for instance, are well equipped. One of them is an electrical engineer, and another is an insurance man, but the average young man in a community doesn't get any special qualifications for anything. He may take a clerk's place in a store, and he will have to stay there for years and years, getting \$30, \$40, \$50, \$75 a month. Seventy-five would be considered a good salary, and he will spend it all nearly, but he will enjoy life.

Q. (By Representative LIVINGSTON.) You have a State Agricultural College here?—A. Yes.

Q. With an agricultural course?—A. Yes.

Q. Do many students take that course when they enter college?—A. No, sir; very few.

Q. Do they go there for engineering or some other purpose?—A. Lawyers, journalists, merchants.

Q. I was going to ask about the school facilities in the rural districts compared with what they used to be 30 or 40 years ago.—A. They are fairly good; better than they were, but not as good as 30 or 40 years ago.

Q. You have the public school system?—A. Yes.

Q. Supported by the county?—A. The public school does not furnish as good teachers as the private schools do.

Q. The white children attend public schools?—A. Yes.

Q. How many months a year?—A. Five months, I believe.

Q. That is the rule throughout the State, is it?—A. In the cities and towns they teach 9 months.

Q. Do you maintain separate schools for colored children in the country?—A. Yes.

Q. Are those schools maintained at public expense also?—A. Yes.

Q. With colored teachers or white teachers?—A. Sometimes one and sometimes the other; generally colored teachers.

Q. And how many months a year are those schools open?—A. Some for 5 months in the country, generally 9 months in the city.

Q. And sufficient facilities are supplied for colored children?—A. I think so; no difficulty about building schoolhouses in the country. A few men get together and put up a house in a day or two that answers all purposes for an ordinary school.

Q. What are those teachers paid?—A. I do not know; I suppose very few are paid as much as \$40 a month.

Q. It is according to the grade?—A. Yes.

Q. They are examined and graded?—A. Yes.

Q. Is it not true that the negro children have the same facilities for schooling in the country that the whites have?—A. I think so.

Q. They are paid from the same fund—the same way and the same amount?—A. I think the negro schools have negro teachers, and they are not as well paid and as well clothed as the whites.

Q. (By Mr. RATCHFORD.) What proportion of the people in your State are colored?—A. I suppose about 40 per cent.

Q. What portion of the tax is paid by that 40 per cent?—A. I have seen that stated often in political papers. I suppose 5 per cent.

Q. What part of the tax belongs to the school fund?

The WITNESS. Of our general tax?

Mr. RATCHFORD. Yes.

A. I do not remember. A large part of the school fund comes from the State railroads and the liquor tax, and some other special tax.

Q. There is no discrimination in the expenditure of the school funds as against colored children?—A. Not that I am aware of.

Q. They receive the same benefits from the general school fund as the white people?—A. Practically the same. I do not think they give them quite as good accommodations, but practically they get a full share.

Q. (By Senator KYLE.) And your statement is that the white people pay about 95 per cent of the tax?—A. I think so.

Q. (By Mr. RATCHFORD.) Do the colored people as a rule receive the same salary for teaching as the white teachers do, when their conditions are equal?—A. I do not think they do.

Q. (By Representative LIVINGSTON.) You must remember that they are compelled to have or stand the same examination, and you say if a negro teacher takes the first grade he gets first pay?

(No response by the witness.)

Q. And the pay is regulated by law?—A. That is regulated by the county board.

Q. (By Senator KYLE.) Is there a complaint among the farmers that they are unduly taxed as compared with business men in town?—A. I do not know. I do not hear much complaint. The farmers do not know how much tax they pay. There are no complaints amongst the farmers about the direct tax they pay. That don't amount to much.

Q. (By Representative LIVINGSTON.) He knows the direct tax?—A. Yes.

Q. But he don't know what he pays in customs duties?—A. No; he does not know what he pays in a thousand different ways.

Q. (By Senator KYLE.) Is it not true that everything the farmer owns is in sight?—A. Everything the farmer owns is in sight. He pays the biggest part of the tax of the State—no question about that. He can not hide what he has, unless he is rich and has some stocks and bonds. He generally pays taxes on his farm, mules, horses, cattle, and furniture.

Q. There is no escaping that at all?—A. No; and if he doesn't give in the property at a fair valuation some of his neighbors will grumble, and complaint will be made, and the apprehension that he may be raised in his valuation generally keeps him up pretty well to the average valuation.

Q. (By Representative LIVINGSTON.) Under the law requiring that the tax assessor shall put his books before the grand jury every spring term, it is made the grand jury's duty to examine farmers' returns, and are they not empowered to have them reassessed and make them pay over again?—A. That is what I had in mind.

Q. (By Mr. RATCHFORD.) Have you a board of equalization in this State?—A. No, sir. We had several years ago, but it lasted only 2 years. I think our system of taxation is most barbarous, unjust, iniquitous.

Q. What would you substitute?—A. I would substitute the single tax. I would take all taxes off personal property, whether it be the result of brain or manual labor. In other words, I am a single tax man. The merchant pays no taxes; he takes it out of his clerks or customers, but the farmer can not shift it. There is no one below him but the negro laborer, and he is already on barely subsistence wages. Everybody shifts it on down to the farmer, and he has to pay it. He pays his merchant, his doctor, his lawyer.

Q. Don't you think the farm laborer who is working for 50 cents a day pays his share of that tax?—A. Yes; I think the laborer pays all the tax.

Q. Don't you think he pays the bulk of it?—A. I think the common laborer bears the burden of the tax, indirectly. Of course the direct tax is put on other

persons and trades, and is handed down. If you put a heavy tax on his business he can not pay as high wages; in other words, he makes his employees pay it. If the physician is heavily taxed he will be more particular about collecting his charges, and it is handed down in that way until it gets to the bottom. There being a great many more of the unskilled laborers than of all other classes put together, they pay the bulk of it.

Q. (By Senator KYLE.) In regard to farm machinery, does that cut much figure in these States?—A. Not much. It does not benefit the laborer, but it benefits the farmer.

Q. What are the new improvements in regard to raising cotton as compared with 25 or 30 years ago?—A. I do not know of any.

Q. The same old style?—A. They have introduced to some extent 2-horse cultivators that will plow out a row at one trip, but they do not use them much in Georgia.

Q. They have to hoe the cotton the same as before?—A. Just as they used to. It costs about as much as it did 40 years ago. The improvements are usually in the way of selection of seeds, fertilizers, and preparation of land. There is an improvement in farming, but not so much in farm machinery.

Q. Improved machinery will come into use with more growing of cereals?—A. Yes.

Q. (By Representative LIVINGSTON.) To cheapen the raising of cotton two things would be necessary that never have been invented and never will be—a cotton picker and a cotton chopper?—A. Yes.

Q. You do not believe they will ever get them?—A. I do not think so.

Q. Where we raise cotton, we are compelled to use the common hoe and ordinary plow.—A. Yes.

Q. And when we pick, we are obliged to do it with the fingers.—A. Yes; that is the principal item of expense—gathering the crop.

Q. (By Senator KYLE.) One other problem concerning the farmers of your section, is the transportation of your crop when raised. You find a home market for all your product, do you?—A. We sell it in the local market. Thus the farmer does not have to haul his cotton very far; perhaps 5 miles would be an average.

Q. It is usually manufactured within the State?—A. They say they can't get enough factories to consume it, but I guess most of our cotton goes to New York yet. I think so.

(Testimony closed.)

ATLANTA, GA., March 19, 1900.

TESTIMONY OF MR. J. E. NUNNALLY,

Farmer, Nunnally, Ga.

The subcommission of the United States Industrial Commission met in the parlors of the Kimball House at 10 a. m., Senator Kyle presiding. Mr. J. E. Nunnally was introduced as a witness at 12.07 p. m., and, being duly sworn, testified as follows:

Q. (By Senator KYLE.) You have read a plan of inquiry?—A. I have seen it.

Q. You may state your full name and post-office address and occupation.—A. J. E. Nunnally, Nunnally, Ga.

Q. Your occupation?—A. Farming.

Q. You are a planter?—A. Yes.

Q. How much ground do you cultivate?—A. About 400 acres; between 300 and 400.

Q. Mostly what?—A. Cotton.

Q. Entirely cotton?—A. No, sir. I never bought a bushel of corn in my life until last year; and I have always been a planter of oats. I raise all the cotton I can.

Q. That is your money crop?—A. Yes.

Q. You aim to produce the cereals necessary to feed the animals and the family?—A. Yes, sir.

Q. You have some stock in addition to this?—A. Yes; I have stock to equip the farm.

Q. (By Mr. SMYTH.) How many plows do you run?—A. Nine.

Q. (By Senator KYLE.) Do you buy your mules in the market?—A. Yes, generally.

Q. You do not raise them?—A. No.

Q. Do you consider that you can buy them cheaper than you can raise them?—A. Yes.

Q. How many bales of cotton did you make this year?—A. Sixty-five.

Q. How many to the acre?—A. About 2½ acres to the bale this year.

Q. How did that compare with the crop last year?—A. Last year I made a bale to every 2 acres I planted. That is generally my estimate of the crop. If I can get 3 acres to make me a bale of cotton I consider it very good farming.

Q. That is half a bale to an acre?—A. Yes.

Q. (By Representative LIVINGSTON.) Have you sold that cotton?—A. Yes.

Q. What did you get for it?—A. I sold it all in one lot in February at 7½ cents.

Q. (By Senator KYLE.) Were you able to hold it on?—A. I could have held it.

Q. What is your observation in regard to farmers generally in your locality? Are they able to hold the cotton?—A. Not 1 in 10. The farming in my community is done by small farmers on 1 to 2 horse farms. We have very few farmers that operate more than that. The farming is done on the half system, or tenant system, as we call it.

Q. Explain that plan—the system of tenant farming as applied to the South. Give it in detail.—A. To avoid a great many questions I simply wrote on those 2 lines, and will read what I wrote. I think it will answer all questions without any inquiry. I devoted an hour to it. I have a few thoughts here that cover that point. I thought it might facilitate the examination here.

(Here the witness read paper.)

“CONDITION OF LABOR.

“Being a Southern man, my experience with labor and agriculture is limited entirely to the labor employed in that section and to Southern products and methods.

“Fifty years ago our laborers in the South were slaves, and on their work in the fields depended the success of agriculture in the Southern States. My experience runs from antebellum days down to the present. But even in those olden days of luxury and ease many discrepancies were discernible in our system. A man so unfortunate as to be obliged to face poverty from the beginning in the majority of cases remained poor, the odds against him being too great to overcome. The advantage gained by the inheritor of wealth only added strength to the chains that bound his less fortunate brother. That day is passed, and happily so, for the American people. Then progress in agriculture and appliances was at a standstill, owing to the capacity of the labor. The implements of husbandry were few and primitive. The watchword was, ‘cut down, wear out, and move on to more productive fields,’ only to keep in perpetual motion the same destructive theory. Our country was then rich in its virgin fertility, our hills and valleys clothed in beauty lavishly bestowed by a Divine hand, whose royal favors, misunderstood and unappreciated by the greedy recipients, were marred and robbed of all their loveliness for gain.

“But the day of waste and devastation is over and the ruinous order of the past is exchanged. The shorn valleys, the old red, gullied hills, the bald and rocky knolls have been reclaimed and once more blossoms as the rose. The richness of the earth and its fullness have been discovered to blinded eyes, and on those plundered lands to-day are produced far richer crops than in their early freshness. The olden appliances are being supplanted by the best inventions of to-day. The work of 6 or 8 men is now accomplished by 1. The hard and tedious work of the old reaping hook is but a dream of the past. A McCormick reaper and 2 mules do the work of 8 good men. As to increase or decrease of labor, if you ask numerically, I would say 33 per cent less to-day than at the close of the war in '65. Not that our population has decreased—it is a well-known fact that it has steadily increased. The work is now done mostly by men, the females being employed only in the light work, such as chopping corn, hoeing, and picking cotton, but a large majority remain in the house the year around. Work is so facilitated by improved machinery there is really less necessity for so much manual labor.

“As to the comparative condition of labor now and 35 years ago, when our slaves became free men they were thrown from a position in which they had been fed and clothed, without care or forethought on their part, upon the resources of their own judgment and inclination. The negro loves a jolly good time. With plenty to eat and wear for the present and a few dollars to spend at Christmas, he reaches the height of his ambition. Of course there are a few exceptions. They are the happiest, most care-free people in the world. But little progress has

been made by them in accumulating and saving wealth. Very few own homes of their own, and not one in a thousand cares to provide for to-morrow, always depending on his employer to furnish food and clothing for the next season, covering his half of the crop.

"All that is done on the farm outside of this system is done by the landowners and their families. Improved machinery has greatly aided these white farmers. They employ 1 or 2 hands, white or black, to aid in cultivating the crops, filling in the time with chores. Wages paid these hands range from \$5 to \$8 per month, with board and house room, seldom reaching \$10 per month. The greater portion of farm work is done on the share plan, the lion's share of expense being borne by the landowner, he furnishing land, stock, feed for same, all farming implements, half fertilizers, dwelling houses, garden plot, firewood, etc., the tenant furnishing labor and food for the same, the crop being equally divided between landowner and tenant. This ruinous system has done more to impoverish and retard the progress of our farmers than any other combination of circumstances. It had its origin in lack of money with which to pay for labor in the first place; then the price of farm produce and its continual decline since '85, still depleting the revenue of the land owners. The labor thus employed only works about 7 months in the year. The rest of the time is devoted to loafing, fishing, hunting, having a general good time, and, I fear, breaking the command which is one of the 'shalt nots.'"

Q. But the man who works by the month at from \$5 to \$8 is supposed to work all the year?—A. Under this yearly contract we sometimes contract to allow them 2 months in the year that they just loaf like the others. We have to do it in order to meet the circumstances around us. We can not simply employ a laborer for the whole year; we must allow him 2 months in the summer season after the busy season is by.

Q. (By Mr. RATCHFORD.) Do his wages go on?—A. No, sir; that stops.

"Our contracts on this line have grown looser and looser each year until the tenant ignores the boss by bossing. This system may have been the best at the hour of its adoption to succeed in cultivating our lands, but taken altogether it has been a stumbling block in the way of prosperity and progressive and diversified agriculture. Tenant as well as landowner has grown poorer year by year under its oppression. All cotton to the exclusion of grain, stock, and cattle is a stupendous error that requires heroic treatment before the mischief wrought can be counteracted. It is plain to the most casual observer that the laudable ambition for plenty and prosperity can not be reached by pursuing a shadow while the substance escapes. There is a solution to the most intricate problem, and there is one to this. So it behooves us by the most careful study and wisest guidance to discover it, treating our fellow-men, both laborer and employer, with due respect and justice. Loans are made to tenants by landlord or merchant in 9 out of 10 cases, all of which is secured by mortgage on the crop or crops to be planted by the tenant.

"Under our Georgia laws, in the absence of a contract, the landlord is first paid out of the tenant's half interest for supplies furnished tenant with which to make the crop, and what is left goes to tenant. This law has worked well in Georgia, giving protection to landlord and at the same time bread and meat to the tenant. It is sometimes used to defraud other creditors, but this seldom happens, and only by men that are paid by the tenant to do so. The greater portion of our field labor comes from our colored population. About 20 per cent are white. All share alike. The contracts are made on the same basis to each race. The State gives to each race the same privileges in our common schools for the education of the masses. A school term of 5 months is provided and paid for by the State. This covers all the time that can be taken from the farms during each year, and some progress is being made in the education of the masses.

"I know of no legislation by Congress that would better anything in this paper more than an appropriation to aid our common-school system. That we need more money along these lines is apparent from the small pay received by our teachers for the services rendered."

That is all that I have written. If I had had time, I would have finished what I had to say along the lines of this inquiry. Now I am ready to answer any questions that I have not answered.

Q. (By Senator KYLE.) You have sons operating with you on the farm?—A. No; I have no children. I manage my farm myself.

Q. By white or colored labor?—A. I have both.

Q. White overseers?—A. No, sir; I am the boss.

Q. Your plan is to work by the tenant plan?—A. Yes; altogether. I only keep one man to wait on me.

Q. You still pursue this system that you consider iniquitous?—A. Yes, sir; I can not help myself. I can not get the labor to work otherwise.

Q. You intimated that there is a solution to this problem; what is it?—A. Simply to adopt the other plan, and everybody hire labor by the day or month.

Q. These men hired at \$5 and \$8 a month, they are satisfied?—A. Perfectly so. If you give \$3, they are overjoyed.

Q. If you hire white men, what do you pay?—A. Eight dollars, and furnish him with a house to live in.

Q. (By Mr. RATCHFORD.) Why don't you try that plan?—A. I have, but I could not succeed while all my neighbors worked on the other plan.

Q. Is the plan you are following more profitable to you?—A. It is under the circumstances; and under the low price of cotton it was the only one under which we could work.

Q. Is it less profitable to the laborer?—A. It throws him on his own resources more. He is dependent on his half of the crop, and if he does not make it, he does not have it.

Q. Under the other system, it is assumed that the reliable workman will raise the best crop it is possible for him to raise?—A. There is a don't-care about our labor.

Q. I am speaking about the reliable man, such as you would seek if you wanted to employ labor.—A. Yes, sir; I should want to make the best crop I could; that is true.

Q. You spoke of slave labor. How much, if any, is the condition of the colored man improved over that of slavery by the present condition of farm life?—A. Well, sir, but very little, taking the masses. There are a few that have made some progress.

Q. (By Senator KYLE.) Do they take advantage of the school five months in the year?—A. Oh, yes.

Q. Up to what age; 10 or 12 years?—A. Yes; up to 18.

Q. Do they go to school as long as that?—A. Yes.

Q. They are generally able to read and write?—A. Nearly all the children are now learning to read and write.

Q. (By Mr. RATCHFORD.) You think the colored man was nearly as well off in slavery as he is on the farm to-day?—A. I do not know but he was better off in some respects, but it is better for the country that it turned out as it did, though I owned a large number of slaves.

Q. Is his service on the farm to-day as cheap to the employer and as productive of good results as under the system of slavery?—A. I doubt it.

Q. Was it more productive of results then?—A. Yes, sir. We took our summer months to make our manure. We used no patent fertilizers; we raised all our fertilizers on the farm during the summer and winter months, and carried it out to the field, which can not be done under the present system.

Q. Does the colored farm laborer live as well to-day as in slavery?—A. Not as well.

Q. We have testimony to the effect that he is getting 50 cents a day, and that it requires all of that or nearly all of that to support him. If that be the case, and his labor is given as freely and as fully now as it was in slavery, I can not see that there is any great difference in the cost of the labor to the farmer.—A. If all the farmers in Georgia were to attempt to move along on that line, we should all be defeated in carrying out that kind of process of farming. The whole thing would come right back to this, that we should abandon it and take to the crop system—that they work so much land and we get half of the crop.

Q. (By Senator KYLE.) What is the length of the day's labor?—A. Sunup to sundown, taking about an hour to an hour and a half at noon. Under the tenant system they work pretty much as they please.

Q. (By Mr. RATCHFORD.) You spoke of labor-saving machinery in your paper. Is it your judgment that the hours of labor should be reduced in proportion to the advent of this machinery and the increased capacity of production resulting from it?—A. That usually falls into a man's hands who uses it to his own advantage. Under our general system of labor they are not supplied with it. In fact, we can not trust it to them.

Q. I understand that the machinery, of course, is the property of the owner of the farm?—A. Yes.

Q. But, speaking of the relation of labor to that machinery, is it your judgment that the hours should be reduced when that machinery is introduced and when it aids so materially in the increase of the productive capacity?—A. As I remarked, all that machinery is owned by the landlord, the man that owns the land, and he operates it with his own labor and with that of his family, with the

assistance of one or two hired hands. All that improved machinery is operated that way in my country. There are one or two simple things like cotton-seed planters that we furnish to our tenants, but the tenant does not care for anything but cotton.

Q. (By Mr. SMYTH.) Do you consider the colored tenant intelligent enough as a class to operate improved machinery?—A. That is the trouble.

Q. You have no machinery for picking cotton?—A. No, sir; it is done by hand.

Q. (By Senator KYLE.) The only change you have in the cultivation is in the two-horse cultivator?—A. That is all.

Q. How much wheat are you able to raise per acre?—A. About 10 bushels.

Q. Winter wheat?—A. Yes.

Q. How much corn?—A. About 15 bushels of shelled corn.

Q. Lands are worth what?—A. Lands are worth from \$10 to \$20 an acre.

Q. With buildings on them?—A. Yes; any farm down there will bring that.

Q. Do you notice a tendency among the white young men to leave the farm?—A. Yes.

Q. To what do you attribute that?—A. The low price of products.

Q. Simply that?—A. Yes.

Q. If you had a good price, they would all remain at home, you think?—A. Yes. You never saw a man as anxious as the young men in my section to procure a farm; they will put in a good year's work with the hope of realizing a little. The last 5 years we have realized very little on our cotton crop.

Q. If a man owns a farm and the machinery, and so on, he may make a fair living?—A. Yes.

(Testimony closed.)

ATLANTA, GA., March 19, 1900.

TESTIMONY OF MR. W. L. PEEK,

Farmer, Conyers, Ga.

The subcommission of the United States Industrial Commission met in the parlors of the Kimball House at 10 a. m., Senator Kyle presiding. Mr. W. L. Peek was introduced as a witness at 12.38 p. m., and, being first duly sworn, testified as follows:

Q. (By Senator KYLE.) Please give your name and post-office address and vocation.—A. W. L. Peek, Conyers, Ga.

Q. Your occupation?—A. Farmer.

Q. You are a practical planter, then?—A. Yes, a farmer.

Q. You own a farm of how many acres?—A. About 600 or 650.

Q. You raise cotton mostly?—A. I raise cotton; that is the principal crop.

Q. Do you raise wheat, corn, and oats?—A. Yes.

Q. Enough to supply you?—A. Generally.

Q. What is your observation of farmers generally in your locality with reference to the products they raise? Do they enter enough into diversified farming?—A. I doubt it. Our money crop is cotton.

Q. But if the farmer does not raise the wheat and corn necessary to supply his family and animals, he is at a disadvantage?—A. I should like to preface that a little. What we term farmers in our section of the country are those who work on the farm. We have 2 classes of farmers, one that owns the land and one that does not own the land. We do not make any distinction in our social relation as to names. We do not use the name landlord or tenant; we use the name farmers. The bulk of our farmers, a large per cent of them, are nonlandowners that work for the man who owns the land.

Q. (By Representative LIVINGSTON.) They are really tenants?—A. Yes, or renters.

Q. (By Senator KYLE.) How much cotton does your land produce?—A. You mean mine individually or the average?

Q. Average.—A. About a bale to 3 acres is the average.

Q. What is the cost of raising cotton?—A. When we make a bale to 3 acres it costs about 8½ cents.

Q. That includes every little item of expense?—A. That includes the cost of raising cotton and putting it on the market.

Q. That includes the wages paid to one's own children and the help around the farm that is ordinarily counted in?—A. Everything, not counting wages to children nor wife.

Q. (By Mr. RATCHFORD.) Does it include transportation?—A. Delivering at our depot.

Q. (By Representative LIVINGSTON.) Interest on land?—A. Interest on land, taxes added in, everything of that sort. Where we raise a bale to every 2 acres we can do it at about 7½ cents, and when we get a bale to the acre we can make it for about 6½ cents.

Q. (By Senator KYLE.) What is your observation as to the ability of farmers to hold the crop?—A. There is no ability as a rule with farmers to hold their cotton.

Q. What per cent are obliged to turn the cotton off?—A. About 90 per cent.

Q. Has there been a movement on foot to build warehouses and store the cotton, bankers furnishing the money and taking the cotton as security?—A. There has been newspaper talk, but no direct movement. It is discussed through the papers.

Q. Do you think that would be an advantage to the farmers?—A. Not to the man who makes the cotton, as a rule, but the fellow who builds the house—it would help him individually.

Q. The men you refer to are the laborers?—A. Yes, those who really make the cotton.

Q. They are working for wages practically?—A. No, sir. With us as a rule it is the tenant system. We rent out for so much cotton, or we go on the half system, the landlord being at all the expense except the labor and half the fertilizer, which the laborer buys. Our land has to be fertilized to make a crop of cotton.

Q. You have been raising cotton how long?—A. Ever since I was big enough to toddle.

Q. The average price has been what?—A. For the last few years very low. You know cotton immediately after the war was away up, but since 1872 it has been falling gradually, until last year it was 4 cents.

Q. In 1890 it was what?—A. I forget. You have and can refer to the statistics. I remember very well that in the fall of 1892 it got up once to 10 cents.

Q. According to the figures here, in 1865 it was 83 cents. Coming down to 1873 it went down to 18, and in 1872 to 20; 18 in 1873 and down to 14, 12, and 10—9 in 1886; 11 again in 1890, 9 in 1891, 8 in 1893, 7 in 1894, 6 in 1895. That is as far as it is carried here.—A. In 1892 when it was announced that Mr. Cleveland was elected it jumped to 10 cents. Last year, you know, the crop sold principally at about 4 cents.

Q. If it costs you 8½ cents, you have been raising it at a woeful loss for the last few years.—A. Yes sir; so much so that nearly everybody has lost a home in this country. I have partly escaped, but the majority of people who farm are now homeless.

Q. (Interrupting.) A man with no mortgage on his farm is able to worry along?—A. A great many have had to mortgage their land and lose it.

Q. To what do you attribute the low price of cotton in the last few years?—A. I attribute it to the lack of money.

Q. Bank facilities?—A. Bank facilities—the farmers have never been able to reach banks. They pay no attention to him. The banks look for larger fish.

Q. I have heard it stated that there is always a scarcity at the time of moving the crop.—A. The crop can always get moved at the price from the planter to the manufacturer. There is no difficulty about that. The trouble is for the farmer to get sufficient price to make money.

Q. Is there too much cotton raised for the consumption of the world?—A. No, sir; there never was too much of the fruits of the earth raised, in my judgment. There has been an underconsumption.

Q. When cotton goes down so very low, is there not more profit in raising wheat or corn?—A. There is not anything in the world in the South that will bring in a dollar during the summer months—I mean a cash dollar—but cotton. We can raise our surplus of wheat and corn, but we are compelled to have some money, and nothing will bring it but cotton on our markets.

Q. (By Mr. SMYTH.) What did you sell your crop at this year?—A. I commenced at 5 and sold up to 6½ and 8 cents.

Q. Did you hold any cotton?—A. No.

Q. What has caused the advance in the price of cotton?—A. I attribute it to the world coming to the opinion that there is a small crop and no surplus behind it.

Q. It is the shortage that has caused the rise?—A. I think that is right, partly. In other words, I think the cry of overproduction of cotton has had some tendency to hold cotton down heretofore, but the intelligent world has figured it out that there is no oversupply, no more made than there is a demand for; and that,

together with the short crop, which will probably fall a million or a million and a half bales short, has brought us better prices.

Q. Do you think you would have had better prices had you raised as much this year as last year?—A. I think only to some extent.

Q. You do not think, then, that the short crop has had anything to do with the advancing of the price?—A. Somewhat, of course, but I think we should have got a better price than we had before, as I told you.

Q. (By Senator KYLE.) What do you think in regard to this system of tenant farming?—A. It is all we can do in the South. Our laborer wants some liberty. The wage system is constant work, constant employment, his time belonging to the other man. Under the tenant system he takes a good deal of time and has liberty to go and come as he pleases.

Q. Which is best for the workman?—A. I do not know how to value his time as compared with dollars and cents.

Q. He bears some of the responsibility, of course; learns to assume responsibility in working for himself?—A. Yes, sir; a little.

Q. (By Representative LIVINGSTON.) Are these tenants usually of sufficient intelligence and information to preserve and take care of a farm and cultivate it as it ought to be cultivated?—A. I think a great many of them have plenty of intelligence, but there is a tendency in the South with our tenants to get out of doing anything that keeps up the farm. In other words, as you gentlemen well know, our land here was much worn under our old system of farming, and we have had to bring it up by particular methods. For instance, the terracing system is doing a great deal to bring back the fertility by keeping it from washing, and the average tenant does not care to do that thing. He does it in some instances, but it is rather reluctant.

Q. I gather from your testimony and others that there are few responsible colored men who will rent a farm and go to work and do as a white man does in the North?—A. That is right; very few.

Q. Do any considerable number of colored men own lands?—A. A few years ago they did, but they have generally lost them. Immediately after the war, the first 10 years, some colored men bought homes; and after the price of cotton got so low, as a rule they lost them.

Q. So that there are very few colored farmers in the South that own their own land?—A. Yes; but few.

Q. Most rent individual farms?—A. Yes.

Q. Most work by the month or— A. (Interrupting.) Or on the tenant system; and I think that will apply to the entire State.

Q. What have you to say as to the future of the negro?—A. Well, sir; it is a tender question, one I do not want to discuss.

Q. He has advanced in regard to education?—A. He will go to school every day in the world that he has an opportunity, and in Georgia he has the opportunity of the white man.

Q. His plane of morals is rising?—A. I could not say that it is.

Q. (By Mr. RATCHFORD.) Does it not follow the negroes' education, a higher moral standard?—A. Well, it ought to do it.

Q. (By Senator KYLE.) You have negro institutions in the State?—A. Yes.

Q. Industrial schools?—A. Yes. The negro in Georgia stands with the white man in regard to educational facilities.

Q. The public-school facilities are the same?—A. Yes.

Q. You have public institutions of an advanced character, have you?—A. Yes.

Q. (By Representative LIVINGSTON.) You have no industrial school in Georgia?—A. Yes; at Savannah.

Q. There is one in Alabama?—A. Yes; they have one in Alabama and one in Savannah, Ga.

Q. (By Senator KYLE.) These students are taught trades?—A. Yes, sir; just as in the white schools.

Q. What percentage of the colored population are employed on the farms?—I should think about 75 per cent of the colored people in Georgia are employed on the farms.

Q. (By Mr. SMYTH.) Women, children, and men?—A. Everything; yes, sir.

Q. Quite a proportion employed in town as laborers generally?—A. Yes. Under our farming system the negroes catch at every little thing. Prices have not been remunerative, and there is a disposition to get away from the farm to other employment. There is quite a disposition of both the white and colored to move off.

Q. White and colored?—A. Yes; laborers, and not only the laborers but the landowners, to get away from the farm. In some sections of Georgia the farms

are turned over entirely to what we call tenants. The landowners have left them.

Q. Gone to the towns?—A. Yes.

Q. The negroes flock to the towns too?—A. Yes; very rapidly, too.

Q. What do they do in the towns?—A. Not being a man who lives in town, I can not tell; all sorts of work, street work, porters on trains, brakemen, hotel waiters, and bootblacks.

Q. (By Senator KYLE.) Do they get an advance in wages?—A. Wages are generally better than in the country.

Q. About what hours of labor?—A. The man who works on a farm in Georgia regulates his own hours of labor—I mean the tenant. He is not forced to a certain time—strict hours.

Q. Farming, then, is not considered a very desirable employment?—A. Not in Georgia. If we could get out the capital we have invested in farms, as a rule, the majority of the men would go into other business.

Q. What percentage of the farmers own their land without mortgages?—A. About 20 per cent. I believe the Eleventh Census showed that 21 per cent of the inhabitants of Georgia owned their own homes; about 19 per cent in the cities and perhaps 21 per cent and a fraction in the country.

Q. Eighty per cent, then, do not own them?—A. That is right.

Q. They must be renters—that is, the white?—A. White and black.

Q. That takes in tenant farmers as well?—A. Yes, sir.

Q. There may be four or five tenants working for you?—A. Yes.

Q. Taking it amongst the whites that own and operate these farms, what per cent own their farms?—A. Twenty.

Q. The balance are renting from some one else who own these farms?—A. Yes. As a rule, they are citizens of Georgia, you understand. There are a few farms owned in our State by loan associations which covered this country a few years back.

Q. The banks foreclose mortgages and such things as that?—A. Yes, sir; some few in my neighborhood have been closed out.

Q. Did that have a tendency to depreciate real estate?—A. There is now a demand for real estate. Real estate has not depreciated in the last 12 months; it has been steady.

Q. But there has been a fall in real estate for a number of years?—A. Yes, sir; no desire to invest in agricultural land.

Q. Have you any immigration from the Northern States?—A. No, sir; not to amount to anything.

Q. No colonization from foreign countries?—A. Some in Georgia—one or two.

Q. Have you anything to say in regard to the system of taxation?—A. Our taxes on the farm are pretty heavy. We pay about 6½ mills in Georgia, and there is nothing in the world we have got that can escape taxation on the farm.

Q. (By Mr. SMYTH.) How do your assessments compare with the real value of the property?—A. Generally very well with its cash value.

Q. Its cash value is taxed about 6 mills?—A. Yes; taxed about 6 mills.

Q. What is the average value of land in your country?—A. Twenty dollars an acre in my home county.

Q. What is the land taxed or assessed there?—A. Twenty dollars an acre.

Q. Is there much of an idle class in your community?—A. Right smartly at times.

Q. With the colored people?—A. Generally colored.

Q. How are they supported? By their wives?—A. They are supported generally by their labor; they are not exceedingly well supported, sir. I think it is a pretty hard living; that is my observation. He is so fixed that he can get along somehow or other with less than average white labor.

Q. (By Mr. RATCHFORD.) Do these people find employment if they desire it?—A. Any time, sir.

Q. (By Mr. SMYTH.) Their labor is in full demand if they want it?—A. Not always.

Q. (By Senator KYLE.) Nobody need remain idle then if they want employment?—A. Nobody, at some kind of wages; I do not say there are remunerative wages.

Q. Do you hire anybody by the month?—A. Yes.

Q. White or black?—A. Both.

Q. What wages do you pay?—A. I pay \$10 a month and rations, as we call it.

Q. That includes provisions, board and lodging, does it?—A. I give a furnished house and patches for them, and pay them \$10 a month, and our custom is to give about 15 pounds of bacon, a bushel of meal, and a gallon of syrup a month, and we generally employ all the wives and children on the farm.

- Q. That is during the busy season?—A. The year round.
- Q. (By Mr. SMYTH.) Do you furnish firewood?—A. Yes; we furnish everything.
- Q. (By Representative LIVINGSTON.) If you received rent for the house, and a reasonable rent for the garden patches, and charged for their wood, with these rations it would run up to about \$15, would it not?—A. Yes, \$15, or about that.
- Q. You practically pay \$15 a month?—A. Yes.
- Q. (By Senator KYLE.) What would you say with reference to the markets for your cereals and cotton in this country?—A. We could market right at our door, within four or five miles; we think this country is pretty well cut up with railroads, and there is always somebody ready to buy your cotton at some price.
- Q. There are no complaints amongst the farmers in regard to overcharges for transportation?—A. Yes; the world is full of it.
- Q. Tell us something about that.—A. I can illustrate that, possibly. I live 31 miles from Atlanta; I pay 15 cents a hundred freight to Atlanta for my cotton; I pay 4 cents a bushel for corn from my place to Atlanta. That is just about the rate of transportation all over Georgia. The transportation is one of the great drawbacks to the farmer, we think. We can illustrate that by the report of our railroad commission in a great many instances, the report of our railroad commission shows that our railroads have earned a dollar for every linear yard of the road.
- Q. For the last year?—A. Yes. That was last year, from the last report.
- Q. Have you anything to say in regard to combinations by brokers and others for the purpose of controlling the price of cotton?—A. They do that.
- Q. For the purpose of bearing the price of cotton?—A. Dealing in futures is a great drawback to the farmers, and it keeps things unsteady.
- Q. I believe you stated that 90 per cent of the farmers were compelled to turn off cotton in the fall?—A. Yes.
- Q. Is it your observation that prices are generally beared during that season of the year?—A. Not always beared.
- Q. (By Mr. RATCHFORD.) Do they usually sell to brokers and dealers?—A. To what we call brokers.
- Q. (By Senator KYLE.) And it goes up after it is in the hands of the broker, as a rule?—A. Yes, always. A man up on the history of cotton knows that to be true.
- Q. Who are the parties responsible for bearing the price of cotton?—A. I think the Government is responsible for it, the United States Government.
- Q. In what way?—A. I think she is all-powerful, and can regulate these things if she would.
- Q. In other words, you say the Hatch bill, prohibiting gambling in futures, should have been passed?—A. Yes; that would help.
- Q. (By Mr. SMYTH.) Is it not a fact that cotton in the last few years has been higher in November and February?—A. Yes.
- Q. Has it not been higher in October than in February?—A. I do not think so.
- Q. I think so.—A. Last year cotton was 6 cents in February and 4 cents in October; that is what my cotton bill shows.
- Q. How about the year before?—A. I think it ran nearly the same way; I would not say for certain.
- Q. (By Representative LIVINGSTON.) Is not the low price of cotton in October, November, December, and January largely to be accounted for from the fact that very nearly the entire cotton crop of the South is sold in these 4 months?—A. Yes; the farmer's financial condition forces him to sell.
- Q. How long does it take to spin it, 12?—A. Manufacturers say 12 months.
- Q. If any other crop was disposed of in the same way, would it not depress it in price, and would not the outside world take advantage of it? Suppose all the mules that would be sold in the next 12 months were crowded into 4 and sold in 4 months, would it not reduce the price of mules immensely?—A. Is it not true that all the mules that are sold are sold within 4 months? They are just about the same way; they are sold just so. And the wheat crop is pushed on the market in just about the same way as the cotton crop.
- Q. If the last cotton crop could have been sold, one-twelfth in September and one-twelfth each month, running along until the next September, what would have been the price of cotton in October?
- The WITNESS. If it had been known?
- Representative LIVINGSTON. If the world had known that one-twelfth was to be sold each month, what would have been the price?—A. If the world had known that I was able to hold it, it would have brought a better price; but if this world had known that that warehouse man had a lien on that cotton, and that he could

close me out at a certain time, it would not have had any effect. I am not favorable to the syndicate warehouse system.

Q. I want to ask you this question: You say the farmers are not able to hold. What plan would you suggest to enable them to hold and scatter this sale along throughout the year?—A. There is only one plan to my knowledge, and that is the old alliance warehouse system.

Q. That is what we are talking about.—A. It is a system—syndicate of systems.

Q. Well, the Government was a system.—A. They were to advance to a certain per cent.

Q. So these people offered to advance at 5 per cent?

Q. (By Senator KYLE.) It would not be profitable for the syndicate to close them out?—A. Yes. If it was so arranged by the directory or by law that these men could not close a fellow out just when they saw an opportunity, and if at 12 months, as we asked the Government, then it would be all right. But we are all human beings, every man, and the purpose of syndicates, if I understand it right, is to make money; and if they get to such a point that they can squeeze me, if they have the right to do it within 12 months, then I am gone. I want to express myself right here, that I have felt hopeful and feel hopeful yet that much good would come from this commission; and if you can do anything to help us, we want to be helped, because we are away down.

Q. Would not a plan of that kind, to rent of the Government or rent of a syndicate, have a tendency to put the farmer on his legs so that he could take advantage of the demand for cotton and sell as the demand grows?—A. I think it would have some tendency to help.

Q. (By Mr. SMYTH.) It would not help the renter though?—A. No, sir, as a rule, until the land owner can get in such a condition that he can assist the renter too.

Q. The plan now—the landlord takes the crop from the renter in October and November, if he chooses to hold out this much.—A. Yes; as soon as gathered.

Q. And any advance in price, the landlord gives the renter generally?—A. At his option.

Q. (By Representative LIVINGSTON.) If we should carry that cotton in the warehouse for your tenants and my tenants, why would they not be benefited?—A. They would if we were benefited.

Q. Then it would be our fault if the tenant was not benefited?—A. That would help, if we are helped by it.

Q. There would be a discrimination against the farmers who did not do it. They would see your tenants getting advantage of it, and my tenants getting advantage of it, and they just would not work without it. They would force the farmers to carry it into the warehouses. Does it have that effect to a large extent?—A. If that plan can be carried out as you say—and I am not to be squeezed in 12 months—then I can help men who work with me, and so on, if I should be helped.

Q. (By Mr. RATCHFORD.) The danger that you apprehend is that the syndicate will have certain provisions in its contract that would enable them to take advantage of the men who can not meet obligations at the end of the year?—A. That is right.

Q. (By Representative LIVINGSTON.) If they carry cotton to the end of the year, it is no advantage, that is true. They ought to be able to sell out cotton at an advantage.—A. I do not propose to hold it, and there is nothing that laps over except tobacco.

Q. (By Senator KYLE.) I think, in addition to this system, that you can diversify farming and enable the farmers to exist.—A. That perhaps would help us.

Q. We shall be glad to have you make any suggestions along the line of remedial legislation.—A. Now, the South is rapidly going into industrial slavery and our lands are all going into the hands of a few men, and I attribute it to two or three causes, and I believe it can be remedied. Just a few years back, you know, 120 years ago, this Government was formed. Now, at the age of 120, if you will take the abstract of the Eleventh Census you will find that about 65 per cent of your citizens are homeless—have got to ask somebody for a place to live and put their heads. In Georgia we have 80 per cent in that fix. That is our fix to-day if the Eleventh Census be true. There are several causes which have brought that about; the causes I do not want to discuss, but it is so. We are a nation of tenants—a man without a home don't love his country, I do not care what you say about it. I want to tell of a remedy for these things, because I understand that one man doesn't know it all and that we learn from each other. Our laws govern our financial relations and social relations. The first thing we want to change is our financial system. I have no opportunity to get money

out of the bank under our national banking system. In the first place the banking system of this country says to the banks, you shall not loan money on real estate.

Q. (By Mr. SMYTH.) You have no State banks?—A. No State banks of issue.

Q. I mean to loan money?—A. They are few and far between. There are some loan associations—that is what we call them—that loan for enormous prices; you must pay all the fees and everything else; we have few banks that loan money. I have never been able to find one of them yet that would loan on real estate as a rule, only at ruinous interest.

We are certainly an exporting people, and all our agricultural exports are sold at the price of pauper-labor agricultural products, and we pay a bounty or tariff on everything we consume. The protective system is right, but it is not carried far enough. You force the farmers to sell at prices, competitive with pauper labor. To make that tax even, every agricultural product that passes out of the United States should have a bounty paid on it, and for the reason I just gave.

Q. (By Senator KYLE.) That is in support of what is called the export bounty bill introduced in Congress?—A. Yes. There must be a change in our transportation system; there has got to be one. It is of no use to argue that, because you are intelligent gentlemen, and you have had it argued before you.

Q. What way would you advocate? Some increase of the powers of the Interstate Commerce Commission?—A. If I read right, our State and interstate commissions are just as helpless as I am to enforce that law.

Q. And would you advocate an amendment to the law?—A. I would advocate some kind of an amendment, but I would advocate Government ownership of all public utilities and transportation.

Q. Pending that; that is quite distant?—A. Then I would advocate that the government we have to-day have power to enforce decrees.

Q. (By Mr. SMYTH.) Have you read the recommendations of the commission on that line?—A. No, sir; I have seen them.

Q. (By Mr. RATCHFORD.) Government ownership and Government regulation and control?—A. I believe in Government ownership, and I think you and I, young men as we are, shall live to see the time when we shall be obliged to do it. Syndicates are eating up this country everywhere.

If you want America to remain America you want a citizenship. If you want to be true to the flag you have got to restrict land ownership in this nation, and provide them a home. God's earth is large enough for all. When Rome fell, 1,800 men owned the known world. Thirty-five per cent of the citizens of the United States own the United States. You know it just as well as I do.

Q. (By Representative LIVINGSTON.) You mean they own the real estate?—A. I am talking about real estate, and you know, gentlemen, that you have got 4 or 5 men in the Government who could buy the whole State of Georgia, boots, breeches, and everything else.

One more thing, you have got to do is to make the homestead secure. You have got to relieve it of taxation or fix it so that it can not be taken under any consideration whatever. If you will do that you will build up a nation that will be a power in the future that the nations of the earth can not overturn and will respect.

Q. (By Mr. RATCHFORD.) Can the homestead be taken under the laws of Georgia to-day?—A. Yes, I can volunteer to give a waiver on my homestead; I should not have the right to do it. I know these are coming questions, and I know you gentlemen are seeking information, but I can go and waive my homestead down there to-day and buy a bill of goods.

Q. I mean, can it be taken by debt without a mortgage?—A. There is no debt without a waiver on the homestead—no note.

Q. (By Mr. SMYTH.) I am surprised to hear you say you have very few State banks in Georgia that loan money on real estate.

Q. (By Representative LIVINGSTON.) You had better correct that, Colonel. We have a great many State banks in Georgia.—A. I said State banks of issue.

Q. (By Mr. SMYTH.) A State bank will lend money on real estate?—A. It is likely that they will; I think they will. Interest under the loan system has eaten up the farms of Georgia. Why force the farmers to borrow money from State banks?

Q. (By Representative LIVINGSTON.) Let me ask you about this home. Allman Bank is a State bank?—A. Private bank.

Q. They loan money on real estate?—A. Yes.

Q. I believe the Clarke Banking Company of Covington—A. That is private—individual.

Q. They are chartered by the State?—A. Not incorporated.

Q. You will remember this company—the Clarke Banking Company—asked permission of the State to cut the charter from \$100,000 to \$50,000, and it was done. You take the Madison Bank and Walton Bank—that is a private bank? I think all that class of banks in Georgia are loaning money on real estate.—A. It is interest paid to these banks that is eating us up largely.

Q. (By Senator KYLE.) What rate of interest is charged for loans on real estate by these private banks?—A. Anywhere from 8 to 12 per cent.
(Testimony closed.)

MEMPHIS, TENN., March 22, 1900.

TESTIMONY OF MR. JOHN C. KYLE,

Lawyer, Sardis, Miss.

The subcommission of the United States Industrial Commission met at the Peabody Hotel at 10.07 a. m., Senator Kyle presiding. Mr. John C. Kyle was introduced as a witness, and, being first duly sworn, testified as follows:

Q. (By Senator KYLE.) Please state your name, post-office address, and vocation.—A. My name is J. C. Kyle. I live at Sardis, Panola County, Miss.

Q. (By Mr. SMYTH.) What is your occupation?—A. Lawyer.

Q. Are you also a cotton planter?—A. Yes.

Q. How many acres do you plant in cotton?—A. I am not really a cotton planter. I rent some of the land and furnish the hands that cultivate it.

Q. Will you describe that arrangement; how you rent your land, on what terms, and the color of your tenants?—A. I have a place near Friars Point that I rent for about \$4 per acre.

Q. Money rent?—A. Money rent. It is subrented for a much greater sum than that. I rent for a sum total.

Q. To one man?—A. Yes, sir.

Q. To a white man?—A. Yes, sir.

Q. He subrents?—A. Yes; to colored people and Italians.

Q. Are there many Italians renting in that way?—A. I do not know of a great many. There are a half dozen families on this place of mine. The rest is cultivated by colored people.

Q. How much land do these tenants have to the family?—A. It depends on the size of the family.

Q. Do they run a 1-horse, a 2-horse, or a 3-horse crop?—A. Some run from 1 to 4 horse crops. I believe the largest farmer that I call to mind on the plantation runs 4 plows.

Q. How many acres does he cultivate in cotton to the horse?—A. About 20 to 25.

Q. Does he plant grain besides?—A. Yes, sir.

Q. He generally raises his own foodstuffs, meat and corn?—A. Yes, sir.

Q. Cotton is the money crop?—A. Cotton is the money crop; yes.

Q. What does that plantation yield per acre?—A. I could not give the exact quantity of cotton. I should think a very safe estimate would be one bale of cotton—500 pounds of lint cotton.

Q. That would be an average crop?—A. Yes; on this particular place.

Q. Some years it would be less and some more?—A. Some years it might be more, rarely less than that on that land about Friars Point. It makes more than that sometimes.

Q. Could that be taken as a criterion of the productiveness of the land around there?—A. In Mississippi?

Q. Yes.—A. No, sir; out in the hills we produce less.

Q. That is what you call the Delta?—A. Yes, sir. I own land out in the hills also.

Q. That is not nearly so productive?—A. No, sir.

Q. How do these hands or tenants run themselves during the year? Are they able to provide themselves with food?—A. They are generally fed from the plantation store.

Q. From the commissary?—A. Yes, sir.

Q. They get that on credit?—A. Yes, sir.

Q. Do they give liens on the crop?—A. No; the statutes of Mississippi give the landlord a lien on the produce of the place to secure him.

Q. These advances are made by your chief tenant who rents from you?—A. Yes, sir.

Q. He makes his arrangement with the subtenants?—A. Yes, sir. I own lands out in the hills where I live that I manage myself. I supply that labor myself.

Q. Do you pay them wages?—A. No, sir. Some of the colored people I have work on shares and some are renting land.

Q. What is the custom about renting on shares?—A. The landlord owns the land and furnishes that, and he furnishes a mule or horse, or mules and horses, and implements; the laborer cultivates it, and they divide the products equally.

Q. Do you use any fertilizer in the hill country?—A. Very little.

Q. You do not use it at all in the Delta?—A. No, sir.

Q. (By Mr. RATCHFORD.) Who furnishes it?—A. I have never used any. I do not know who furnishes it.

Q. (By Mr. SMYTH.) Is that general in Mississippi; no fertilizers used?—A. In southern Mississippi I understand they use a great deal, but we do not use any at all except such as is gathered on the farm—homemade.

Q. Compost piles?—A. Yes.

Q. Coming in on the train we noticed tremendous washes and gullies in the land on either side of the track. It looked like a quarter of an acre in some places had been scoured out for 10, 15, or 20 feet. What causes that?—A. In the first place, you came through a very sandy section of the country. From here to Holly Springs is a very sandy country, and when the water scours its way through the soil and cuts to the sand, it washes very rapidly; the soil is fertile, and the people here have never learned to protect it with sidehill ditches and terracing, as they might. They are learning to do that.

Q. A system of terraces would prevent the washing, you think?—A. I am not sure that it would where it is very sandy, but generally I think it would. I was raised on a farm, and I know something practically about that. I know that when I was a boy my father used to prevent his land from washing by a system of terracing and sidehill ditching, and the old home place on which I was raised is yet in a good state of preservation, owing, in my opinion, to the practice of sidehill ditching; though it is not so sandy there as it is in the country through which you came on your way to Memphis.

Q. Is farming land in this county owned in large tracts principally?—A. Which county?

Q. The county which we are in.—A. This is Shelby County, Tenn. I could not speak about that. The lands in Mississippi are owned in large tracts; in many instances, though, not so large as before the war. You know, perhaps, that our section of the country was owned by large planters who owned large numbers of slaves, and the land was operated and cultivated by that sort of labor. Since the war, from time to time, as the years have gone by, these lands have been divided up, and are now held by small holders in comparison to what they formerly were.

Q. Has there been an increase in the value of land in your county in Mississippi since the war?—A. I can not speak since the war; I know there has been in the last 8 or 10 years, and there is now a very perceptible strengthening in the prices of real estate in our county in the last year or two.

Q. That has shared in the general prosperity?—A. Undoubtedly so. You see, for instance, we have been getting a much better price for cotton. Cotton seed has gone beyond what anybody ever expected it to go in price. I can remember when it was a great source of bother to get rid of the cotton seed that accumulated about the ginhouses. We threw it out and got rid of it in anyway we could. People would complain about the hogs getting in and eating it.

Q. (By Senator KYLE.) What does the cotton seed sell for?—A. From 30 to 33 and 34 cents a bushel.

Q. (By Mr. SMYTH.) That is bought by the oil mills?—A. Yes.

Q. Then the farmer can buy the meal back if he wants it?—A. Yes; but he pays pretty well for it.

Q. (By Mr. RATCHFORD.) How many bushels of seed will an acre yield?—A. I suppose that on an average we make a bale of cotton to 3 acres, and there is about 33 bushels of seed, to the bale.

Q. A bale to 3 acres?—A. Yes, sir.

Q. You were speaking of making a bale to the acre?—A. Yes, sir; in the first instance I was speaking of the delta country. I do not live there; I own a plantation there.

Q. You make how many bushels of seed to the acre?—A. Ten or twelve to the acre.

Q. (By Senator KYLE.) Worth 33 cents?—A. Thirty to 33 cents.

Q. About \$6 or \$7 per acre for seed?—A. Yes, sir.

Q. And in the delta country you raise a bale to the acre?—A. Yes, sir; that is a safe calculation.

Q. And make about \$10 there an acre for seed?—A. Yes, sir.

Q. That is in addition to the cotton?—A. Yes, sir.

Q. Adding immensely to the value of the cotton crop?—A. Yes, sir. We have got the greatest country in the world, if we only knew it.

Q. I want to get at the actual product of an acre of ground, money value. You say it is about \$10 an acre for seed. How much cotton is taken off an acre in the delta country?—A. It is worth about \$40 to \$45 a bale.

Q. It sold for 9 cents the other day. The average then is about \$10 for seed and \$40 for cotton, making \$50 off an acre of ground?—A. Yes, sir. That is only a recent condition. We have been getting until recently about 5 cents for cotton.

Q. (By Mr. SMYTH.) That was only for about 2 years?—A. Yes.

Q. (By Senator KYLE.) What does it cost to grow cotton?—A. I have figured some on that. It varies. I have discussed that with cotton growers, and they do not agree about it. I suppose it costs from \$20 to \$25 a bale to make it.

Q. Whether on the upland or lowland?—A. I think it would cost more on the upland.

Q. (By Mr. SMYTH.) It would cost 4 or 5 cents a pound to raise it?—A. Yes, sir.

Q. Of course conditions vary on different plantations?—A. Yes, the conditions are more favorable in some instances than in others.

Q. More intelligent management?—A. That helps. It costs some men more to raise the cotton than others. Some understand the cultivation better. Some know what sort of plow to use better than others. Some know how to prepare the soil, plant and handle the crop better than others; but on an average I should say it would cost from 4 to 5 cents a pound to make cotton.

Q. (By Senator KYLE.) So when you are growing cotton at 5 cents you come out about even?—A. I think just about even, not much more than that.

Q. You would not say that it costs 8 or 8½ cents to raise cotton?—A. No, sir; I would not.

Q. We had that testimony from some man over in Georgia. A. I do not think that. Of course, being called up here without having thought about this, I have not reflected on it as I should like to if I were going to try to get at these facts accurately.

Q. (By Mr. RATCHFORD.) You spoke of the seed being a waste formerly; how long has it been since the seed has been a source of revenue to the farmer?—A. I suppose 25 years.

Q. Has that change from the previous condition improved the farmer's condition?—A. I think so. I hear this sort of talk among farmers, that the selling of the seed impoverishes the soil and that they do not make money by that course; but formerly when they did not sell the seed, they did not utilize it much for fertilizer.

Q. Do you believe the decline in the price of cotton for the last few years has been due to any extent to the revenue derived from the seed of the cotton?—A. No, sir; I do not think so.

Q. That has come about as a natural consequence?—A. The price of the cotton?

Q. The decline for the past few years?—A. Yes, sir; that is my idea about it.

Q. (By Mr. SMYTH.) Rather due to the law of supply and demand?—A. I think so. I think that is one rule you have to observe in almost any industry when you come to pass on a question of economics; you have to consider the law of supply and demand.

Q. The crop has been constantly increasing?—A. Yes; and we had been accumulating, and in my opinion there was an accumulation of manufactured goods, and we had two immense crops right together. Now the shortage of this crop and the increased demand for cotton goods has put the price up. I might say further that in my opinion while cotton was so cheap the price was so low that people found a great many uses for it that they never knew before. I have seen cotton used in Mississippi in clothing of recent years that we never had before, and I think it was because cotton was cheap and those who were handling it were seeking something to put it into.

Q. That is undoubtedly true; it was used in place of shoddy?—A. That is true. You see it stated in these manufacturers' journals that cotton is mixed with silk. It is mixed with flax, and you see people wearing blouses and overalls now which were never worn in our country before. Cotton got so cheap you could buy these garments for such a very small price.

Q. Do you not think the depression in business existing for 2 or 3 years, covering the period of low prices of cotton, had its natural effect in lowering the price of commodities?—A. I think so. I think the lowering of the price of cotton increased the demand to some extent.

Q. Do you not think the lowering of the price was caused by the depressed condition of business?—A. Yes.

Q. And since business has revived there has been an increased demand for everything?—A. I do not know that I should be willing to say. That would be mere venture without being informed about it—to say that people wear less clothing than they did. I do not know that my observation is that way.

Q. What causes, do you think, led to this revival of business?—A. That leads out into politics a good deal. I think the revival of business in the country is to some extent attributable to the fact that people became reconciled to the condition as it was, and had more confidence in the stability of our conditions, and all that sort of thing, and the shortness of the cotton crop increased the demand for that commodity in the South here, increasing the price, I mean, and that revived business with us, and there were circumstances that increased the demand to some extent for the products of the Northwest—the war has had something to do with it.

Q. (By Senator KYLE.) One other question as to the cost of growing cotton. How much cotton can a man make?—A. With reference to the cost of growing cotton, I do not know that I was as accurate about that as I might be. I stated the cost of growing cotton was 4 or 5 cents. That price was fixed with reference to other conditions; for instance, when corn and mules and farming implements and labor were in proportion to the price of cotton cheaper than now. I do not believe you can grow cotton for 4 or 5 cents now. Mules and horses are worth a great deal more. Plows and all kinds of hardware are worth more.

Q. (By Mr. SMYTH.) What caused the advance of the price of mules? An increased demand?—A. I think so. There has been a demand for mules abroad in the war; and with the increased price of cotton of course almost every farmer that owns land is anxious to put it into cotton and get the best results from it, hence he wants mules. Heretofore he has been a little indifferent about planting so much cotton.

Q. (By Mr. RATCHFORD.) Is an increased price paid to agricultural labor as compared with 2 or 3 or 5 years ago?—A. I will answer that in this way: Where the laborer works for part of the crop, of course his price is increased to the value of the part that he gets.

Q. (By Senator KYLE.) You do very little hiring by the month?—A. Very little. I can not say that there has been very much advance in the price of that sort of labor. The tenant system is almost universal.

Q. (By Mr. SMYTH.) Under that system the laborer shares in the advanced price of the farm product?—A. Yes; and we grow down in our country a great many things besides cotton. He participates in the fluctuation, advance, and decline in price.

Q. (By Senator KYLE.) How much cotton can a man and his wife and 2 or 3 children—boys from 12 to 18 years of age—grow?—A. I think they can work on an average 15 acres to the hand in the section I live in.

Q. Just the family?—A. Each hand in the family.

Q. Fifteen acres?—A. Yes, sir; that means old and young, all that go to the fields. Take a steady, able-bodied man, he can cultivate more than that.

Q. Forty dollars an acre is the gross profit, making about \$600?—A. No, sir; I do not think they can make \$40 an acre out in the hills. They would make about one-third of a bale to the acre.

Q. In the delta they make about \$40 to the acre?—A. Yes, sir. We also grow out in the hills sorghum, sweet potatoes—sorghum is a great crop. It is used on the plantation generally. We raise some sugar cane, not a great deal. We raise sweet potatoes and some Irish potatoes.

Q. (By Mr. SMYTH.) Do you raise your own meat?—A. Yes, sir; more than formerly.

Q. Are the colored people acquiring land to any extent in Mississippi?—A. Not a great deal.

Q. Has there been any advance in the general condition of the race, socially and in intelligence?—A. Yes, sir; I think so.

Q. Have they improved as laborers since freedom?—A. No; there is not much change.

Q. Do you think they have increased in value as farm laborers?—A. Of course, as you increase the intelligence of the man, if it does not go to the extent of putting him in a position to abandon farm labor altogether, it increases his efficiency as a laborer.

Q. You consider them first-class labor do you not?—A. I consider them the best we ever had in the South.

Q. You spoke of Italians. Do you consider them successful cotton farmers?—A. Very.

Q. How do they compare with the colored?—A. They are more energetic and

more successful. The Italian does not stay on these fertile lands long until he has money enough to engage in some other sort of business. He is not, therefore, as desirable as a laborer as the colored man who stays there. The idea of the Italian is temporary employment, and he drifts away to the city.

Q. Is there any disposition in the colored man to drift to the city?—A. A good deal, yes, sir.

Q. What do they do?—A. They get places as servants and about hotels.

Q. Is there much of the vagabond loafing class among the colored?—A. I do not think so. That is not my observation.

Q. What school facilities have you in Mississippi?—A. In what respect?

Q. Public schools.—A. In some of our towns we have now what are known as separate school districts where they run schools about 9 months in the year. That is under a system by which a tax is levied on the particular district to supplement the amount contributed by the State. For instance, in the little town I live in they run the school 9 months for both white and colored. There is no distinction except that the white teachers are paid more than the colored teachers. The colored do not hold as high grade certificates as the white.

Q. (By Senator KYLE.) They would be paid the same for the same certificate?—A. I think so.

Q. How about the country schools?—A. They run about 4 or 5 months in the year. They are supported out of the State funds equally with those of the whites. The schools are kept separate and the races do not mix.

Q. What proportion of the taxes are paid by the whites?—A. I could not answer that. I have recently seen a statement showing exactly what that was.

Q. The bulk of it is paid by the whites?—A. Yes, sir.

Q. (By Mr. RATCHFORD.) What is the proportion of the colored and white?—A. About equally divided, I think.

Q. (By Mr. SMYTH.) Do you know how much the State contributes each year?—A. Our legislature, which has recently adjourned, appropriated \$1,000,000 for public schools, and in the separate school districts there is an additional amount raised by a special tax on those districts, which goes to supplement the amount contributed by the State. That is a local tax.

Q. The \$1,000,000 fund will run the schools for 4 or 5 months?—A. Yes, sir.

Q. And where there is no local tax to supplement that fund the school stops?—A. Yes, unless there is a contribution made by the citizens.

Q. (By Senator KYLE.) Have you a compulsory law?—A. No, sir.

Q. How do the negro children attend, pretty regularly?—A. Yes, sir, generally, I think so. I have not been to a negro school recently. I used to be a trustee of the public schools and would occasionally go to the negro school, but I have not had my attention called to it of recent years. I think the attendance is generally pretty good; they are anxious for an education.

Q. (By Mr. SMYTH.) More than the poor class of whites?—A. No; I think not.

Q. Do the white parents as a rule encourage their children to go to school?—A. I should judge so. It looks to me in our little town as if all the children within striking distance must be in school.

Q. Do we understand that in respect to this State money expended on public schools there is no partiality shown, no distinction between races; that it goes equally to the white and the colored?—A. Not equally.

Q. In proportion to attendance?—A. Yes, sir; it goes equally in this way; there is a system of grading the certificates held by the teachers, and the colored teachers do not generally hold as high grade certificates as the whites, and the salary is based on the grade of the certificate.

Q. (By Mr. RATCHFORD.) There is no discrimination in the school term as between the colored and the white?—A. No.

Q. (By Senator KYLE.) As to hi, her education, you have a State University for the whites?—A. Yes, sir.

Q. What provision is made for the colored?—A. We have a State University for the colored at Rodney.

Q. Is that well attended?—A. I am not informed about that.

Q. We learned that in Georgia they nearly double the attendance of the colored?—A. I have never heard but it is well attended. At Holly Springs there is the Shaw University that the State has been contributing to. The money with which it was built was contributed by some charitable Northern people, as I understand. The practice has been to supplement that with money out of the State treasury every year. I do not know whether they did it this year or not. I know when I was a member of the Mississippi legislature that was done. I think there is a school for colored girls at Jackson. That, however, is not a State institution, but the money is contributed by Northern people. We have an

industrial institute or college for girls at Columbus for whites; that is a State institution. Then we have an agricultural and mechanical college at Starkville, Miss., which is well attended. We have the State University, which is largely attended; that is kept up by the State. In its early beginning there was donated by Congress a township of public land for seminary purposes. That was sold and the proceeds put to the credit of the University of Mississippi. Recently, while a member of Congress, I got a bill through donating another township of public land to the State for seminary purposes, on the theory that heretofore only one township was granted to the State, and when these other States came in they got two townships. They gave us another township 2 or 3 or 4 years ago to put us on an equality with the other States. These lands are located in the southern part of the State.

Q. (By Mr. SMYTH.) Is there much land in Mississippi owned by the State?—A. Yes, a good deal, but not nearly as much as formerly.

Q. Is it the practice to sell that land out?—A. Yes, sir.

Q. Is it in forest mostly?—A. Yes, sir.

Q. (By Senator KYLE.) These negroes attending the universities, do they take a professional course, as a rule, after completing the college curriculum?—A. No, I think not much.

Q. The students of that university—do the graduates become professional teachers, ministers, lawyers, and doctors?—A. Yes, some of them do. There are not many colored doctors; very few; occasionally you find a lawyer.

Q. What is the disposition of the colored people to patronize their own race in a professional line?—A. They do not do that much. I have lived in a town where there were two or three colored lawyers, and I never knew the colored people to patronize them much with legal business. I have lived in a town where there were colored physicians, one at least, and I never knew his people to patronize him very much, and he finally went away; and these colored lawyers have largely gone away.

Q. You consider that the future of the negro is along industrial lines?—A. More than any other, if he has any future.

Q. Of course we are looking to the best good of the negro race as regards education and in other ways. You think there is more hope for him in education along industrial lines than any other?—A. I should say so; yes.

Q. Do you think he is improving as a farm laborer to any great extent?—A. If I said no, that would rather imply that I did not regard him as efficient. I think he is efficient now, as much so as he ever was. I do not think he has made much advancement.

Q. During the days of slavery he was a good workman, a continuous workman?—A. Yes, sir.

Q. In the first days of freedom I presume he was just as good a workman, but not as continuous?—A. Yes; that is true now.

Q. He has more disposition to loaf than formerly, and take a holiday?—A. I do not want to say that the darkies put in much time loafing. I do not think they do that, but they do not work as closely and as diligently as they did when they were slaves, of course.

Q. (By Mr. SMYTH.) Nor as intelligently?—A. Nor as intelligently.

Q. (By Senator KYLE.) They do not seem to have an ambition to own property?—A. Some do, but the great mass do not.

Q. These men, you state, are farming on the tenant plan. Do they ever get to own their own farms?—A. Occasionally they do.

Q. Free from mortgage?—A. Yes.

Q. Do they get into debt and lose these farms?—A. When they get the land and get it free from mortgage they are very loath to encumber it.

Q. These are small farms?—A. Yes.

Q. Do they raise other things beside cotton?—A. Yes; sorghum and potatoes and corn.

Q. So they get their living from the land independently of the cotton crop, which is the money crop, do they?—A. They could do it, but they do not do it. Some of them do; the most do not.

Q. Of course, the happiest condition of the agricultural class is where they own their own homes free from mortgage, whether white or black, and it seems to me that is the ideal situation to look forward to with reference to the renting class. What percentage of the people on farms in Mississippi own their own homes in fee?—A. I could not answer that, because I am not well enough informed about it. I should say the white people generally own their own homes.

Q. The white people?—A. Yes.

Q. The statement was made in Georgia that only 20 per cent owned farms and 80 per cent rent lands.

The WITNESS. Of the white people?

Senator KYLE. Yes.

A. I should not be willing to make that statement, even upon opinion, about Mississippi. I do not believe that is true.

Q. (By Mr. SMYTH.) In Mississippi you think a majority of the white people own their property?—A. I should say so.

Q. What is the condition of the cotton planter now, this year, as compared with former years?—A. I think it is better.

Q. What has been the custom heretofore in regard to the spring crop? Would they have to borrow money from the factor?—A. They would either have to borrow money or get their merchant to supply them.

Q. You are speaking now of the white landlord?—A. Yes.

Q. Then he in turn would supply the tenants?—A. He in turn would supply the tenants.

Q. (By Senator KYLE.) Did the good prices for cotton this last year help them out in that regard?—A. Yes; no doubt about it—good prices for everything else we have had; cattle have been sold at good prices, and sheep have been realizing pretty good prices. Cattle are a commodity that has never been worth much with us until recent years.

Q. (By Mr. SMYTH.) Do the tenants in Mississippi generally hold the cotton to get the benefit of advances?—A. No, sir. I think not; it is just as it used to be.

Q. Quite a number of them hold, I suppose?—A. Yes.

Q. (By Senator KYLE.) What percentage of the farmers are compelled to sell their crop immediately after harvest?—A. I do not know. I should not suppose, however, to guess at it, that over 25 per cent of them do.

Q. Were compelled to sell?—A. Yes.

Q. A good many of them could hold?—A. Yes.

Q. (By Mr. SMYTH.) That class is, of course, an independent class?—A. Yes; I think so. There are a great many people, of course, that, no matter what the prices are, are improvident people. Of course there is a large per cent of that sort of people who do not take advantage of higher prices or anything else and lay by anything for a rainy day. My observation is that more people in the country have money than I have known to have it before. My business is such that people come to me seeking an opportunity to make a little loan of money. I have had people approach me in that way that I would not have thought had any money. Of course that is just the neighborhood around there.

Q. That wanted to loan money?—A. Yes.

Q. (By Mr. RATCHFORD.) From that you judge the condition of the people generally is improving?—A. Yes. Of course there are a great many of these questions that I have not thought about before. I will answer them as they come to me, and put in my opinion of the different matters as they appear to me around home.

Q. Now, about the mortgages on the farms. Have you any reason to know as to the number of farms in your county that are covered with mortgages?—A. No, sir; I have but little information on that. I know a good many people give mortgages.

Q. (By Senator KYLE.) For what purpose do they give mortgages?—A. They give mortgages and borrow money to carry on their business.

Q. (By Mr. RATCHFORD.) Mortgages are not always the sign of hard times, are they?—A. I think not, sir.

Q. You spoke about the plantation store. I should like to have you explain the details of that more fully.—A. Well, sir, a plantation store is a store on the plantation. The landlord generally owns and operates the store and advances the laborer his supplies.

Q. (By Mr. SMYTH.) It is a general store?—A. Sometimes it is a general store, but I would say, strictly speaking, a plantation store; it is just simply to furnish people on the place.

Q. (By Mr. RATCHFORD.) Does the laborer get credit there for his necessities until the crop is marketed?—A. Yes.

Q. Without a mortgage?—A. Yes.

Q. Or any other security?—A. Yes.

Q. Is he obliged to deal at that store? For instance, can he go to the next plantation store and deal there if he wants to do so without any interference on the part of the landlord?—A. I suppose he could if he had outside security. The statutes of Mississippi give the landlord a lien on all crops produced by the tenant to secure the supply dealers, rents, and so on. That gives him credit with the landlord at all times, and he would not have that credit were he a man who was not with the landlord.

Q. For instance, if the landlord should for any reason raise the price of flour, meats, or other necessities of life, would the tenants feel obliged to deal there because of these reasons?—A. I do not know whether he would feel obliged to do that or not, but his environments would be such that they would almost compel him to go there.

Q. As to prices: What can you tell us concerning the cost of staple articles, for instance, flour, meats, coffee, in those plantation stores?—A. I could not tell about that. I do not know what anybody does. I can tell you my practice with reference to my own people.

Q. Tell us your practice.—A. I furnish my people on my lands I work at home at cash prices, just what I have to pay for the goods, and they pay 10 per cent on that.

Q. Cost price, you mean?—A. Cost price; yes.

Q. Are these prices cheaper than the prices generally prevailing in the city?—A. I can not tell you about that. I generally buy as cheaply as any man could, of course.

Q. (By Mr. SMYTH.) You buy wholesale?—A. Yes—I would not say that. Sometimes I can do better at country stores than in the city. Wherever I can buy stuff for my people the cheapest I get it, and then add 10 per cent to the cost of it for interest on the capital. That keeps me even with them, and occasionally a fellow slips out and there is some loss. I do not attempt to make a profit.

Q. (By Senator KYLE.) You have got to do that in order to get a man for your land?—A. Yes.

Q. (By Mr. RATCHFORD.) So far as you know, is that the practice that is generally followed in your neighborhood by other landlords?—A. I do not know, sir. I do that.

Q. There is not any system of issuing rations by the landowner, is there?—A. No, sir.

Q. (By Mr. SMYTH.) There are not many farm hands in your State hired by the month, are there? It is mostly the tenant system?—A. Tenant system.

Q. You were speaking a while ago about the colored people having a tendency to flock to the towns and cities. Do they accumulate property there?—A. No; I do not think they do, much.

Q. When they do it is very hard to get them to sell it?—A. Yes.

Q. They hold on to it?—A. Yes. Now, in the little town I live in there are a good many colored people who own homes there, small houses, cabins only. They are slow about borrowing any money and mortgaging their little homes when they get one. That is my observation with them.

Q. (By Mr. RATCHFORD.) Do the farm laborers, as a rule, school their children between the seasons of crop raising?—A. Yes. The schools, I think, are taught so much in the winter time and so much in the summer, when it is convenient for the children who are on the farms to go to school.

Q. (By Mr. SMYTH.) When the crops are laid by?—A. When the crops are laid by.

Q. (By Mr. RATCHFORD.) And in that way they have opportunities in the country to get a common-school education?—A. Yes.

Q. And at the same time assist on the farm?—A. Yes; that is right.

Q. (By Senator KYLE.) What is paid by the month to farm helpers when you hire that way?—A. I should say from \$6 to \$15 a month.

Q. And found?—A. Yes.

Q. (By Mr. RATCHFORD.) Do the wages vary as between white and colored men where the skill is equal? That is to say, will the colored man receive the same rate of wages on the farm as the white man, where all other things are equal?—A. Yes. If there is any difference, I do not know it. There may be some little difference in favor of the colored man. I think as a general thing people had rather hire colored men.

Q. (By Mr. SMYTH.) As a rule he makes a better tenant?—A. He makes a better servant.

Q. Do you have cotton mills at Wesson?—A. Yes; and at Natchez, Meridian, and then the Stonewall Jackson mills—I do not know what the name of the little town is that has grown up around it there. Some Northern people came down there and started a mill, and a town has grown up there. The name of the mill is known as the Stonewall Jackson mill—and then the Yocona mills.

Q. (By Senator KYLE.) Are you acquainted with the operation of these mills?—A. I am not.

Q. You do not know how much cotton they consume?—A. No, sir; I do not. I have a general idea about it that I gather up in a general way, but I know nothing about the details.

Q. (By Mr. SMYTH.) Have you any laws in Mississippi regulating the hours of labor, or ages at which children should be employed?—A. No, sir.

Q. (By Mr. RATCHFORD.) Have you compulsory school laws?—A. No, sir.

Q. Do you believe such laws ought to be in existence?—A. Oh, well; I do not think I do. I do not believe I am—

Q. (Interrupting.) Have you any shop or factory inspection laws?—A. No, sir.

Q. (By Mr. SMYTH.) Do you think these laws tend to decrease the building of mills?—A. No, sir. I do not know why they should. If there is any reason why I should have an opinion of that sort I do not know it.

Q. You do not think capital is attracted to Mississippi because of the absence of these laws?—A. No, sir; I do not.

Q. (By Senator KYLE.) The factory can operate as many hours a day as it wants to under the present law—14 hours if it wants to?—A. Yes.

Q. In the cities and towns of the State are the hours observed for the working men 10 hours a day?—A. Yes; 10 hours a day.

Q. (By Mr. RATCHFORD.) In the cities of your State?—A. Yes.

Q. Are you acquainted with the number of hours worked in your State?—A. No, sir.

Q. (By Senator KYLE.) You don't know what the hours are in connection with factories?—A. No, sir.

Q. (By Mr. RATCHFORD.) You are not acquainted with the ages at which the children are usually admitted into the factories?—A. No, sir; I am not. I only see them there at work. I suppose they are from 10 years old upward. Some of them are quite small I know.

Q. White labor is employed in factories, is it not?—A. Yes. I do not know any factory in this State that employs colored labor.

Q. Do you think that labor and confinement for 11 and 12 hours each day is injurious to the physical growth and development of the child?—A. I think it would be. I think that is too long.

Q. You think it should be regulated by law or otherwise?—A. I believe it should be regulated by law. Of course, as I have said before, these economic questions I have not thought about much. I believe, though, that there ought to be some restrictions about the length of time children are worked in factories.

Q. But no restrictions as to age?—A. I do not know but I would have some restrictions about the age, too; but I should not be as much in favor of that idea. I think the children in the factory ought to have some time for recreation outside and some mental and moral training.

Q. (By Senator KYLE.) They ought not to be allowed to work more than 6 months a year, for instance?—A. Not so close.

Q. (By Mr. RATCHFORD.) At present the children have little or no opportunities for education, have they?—A. I think not.

Q. Unless they attend night school or something of that sort?—A. Every man, in my opinion, is interested in every child growing up in the community in which he lives. I do not believe that idea is consistent with putting them into the factory and working them all the time that it is possible for them to work. I think they ought to have some time for advancement and mental training, moral training, and physical training.

Q. That also applies to the other sex, does it?—A. Yes.

Q. (By Mr. SMYTH.) Then you would favor a compulsory school law, wouldn't you, so as to force children to go to school, and to compel parents to send them to school under the working age?—A. I do not know. I do not believe I would say that exactly.

Q. (By Senator KYLE.) You think if they had a law forbidding them to work over half a day, or part of a year, they would probably go to school the rest of the time?—A. Yes; that is about the idea I have had.

Q. (By Mr. RATCHFORD.) Have you formed any idea as to the proper length of a day's work for children in the factories? Should it be 8 hours, 9 hours, 10 hours, or should it be even 11 or 12 hours for part of the year, and during the school term no work at all for the children?—A. I have never had any experience in working children in any sort of work, but just from my feelings of humanity and my general interest in children I should say that children ought not to work more than 4 or 5 hours a day—5 or 6 hours, or something of that sort.

Q. (By Mr. SMYTH.) But you have no plan to suggest?—A. No, sir; I have not, but that opinion is not worth anything, because I have not had any experience that would give me any intelligent opinion about it.

Q. You are not well advised about the conditions?—A. No, sir; I am not.

Q. (By Mr. RATCHFORD.) In a general way, have you formed any idea as to the age at which they should be admitted to work?—A. Well, no, sir; I have not.

This is an offhand opinion about it. I would not admit a child into these factories under 12 or 14 years old.

Q. (By Senator KYLE.) There is one other point you have not covered yet; that is the raising of cereals and stock by the farmers of Mississippi. I notice from the reports of the Secretary of Agriculture that there has been a falling off for the past 10 years in the amount of cereals and stock raised by farmers, and that you import some of the things that might be grown by the farmers. Is that because the people have given their attention entirely to cotton growing?—A. I think so; yes.

Q. Depending upon the money derived from that to purchase these other things?—A. The idea is that they can make cotton to buy mules easier than they can raise mules.

Q. Is it not possible for the farmers to diversify their industry in such a way as to make it very profitable?—A. I think so. I do not think the idea that raising cotton to buy mules is easier than raising mules is correct, but it seems to prevail.

Q. What is a mule worth when it is raised?—A. Generally with us we are paying all the way from \$50 to \$100 for mules. You pay \$125 for an extra good mule.

Q. What does it cost to raise a mule? I think Colonel Livingston gave as his practical experience that it cost \$15 to raise a mule ready for the plow?—A. I should say \$20 to \$25. Colonel Livingston, I fear, put the price a little too low. You see, unless a man owns his own jack, it takes \$8 to \$10 to start with.

Q. Suppose it cost \$25 to raise a mule ready for the plow, it seems to me it would be a profitable industry for the farmer, aside from the cotton crop.—A. I think so.

Q. Is the land adapted to wheat and corn?—A. It is adapted to corn, but not to wheat. We can grow wheat some; oats is a surer crop with us than wheat.

Q. Oats and corn can be raised successfully?—A. Yes.

Q. And can not the farmer also have a few milch cows and steers?—A. Yes. As I said a while ago, the cattle industry is looked after a good deal more now than formerly, because cattle are bringing a good price. They are being introduced in our country—the Durham cattle. Jerseys were brought in there years ago, and our country is well stocked with them. You will find milch stock all through Mississippi as often as you will find them anywhere. But in recent years farmers have gotten onto the idea that they want good steers, beef cattle, also, and stock to get a larger breed of cattle; and Durham is being introduced there.

Q. The complaint of the agriculturalists is that after disposing of the money crop there is not more than enough left to settle grocery bills and living expenses of the family. I can readily see how that is the case when a man raises nothing but a money crop, but we have passed through the same experience in our Northern country, of course depending entirely on the raising of wheat, and from that buying oats, corn, and all food and necessities for the family.—A. There is this about it. There are so many engaged in agriculture in all competitive crops that they do not generally make a great deal over what it costs to produce the stuff, and there is not much to lay by anyway.

Q. But I refer to cotton as a money crop, and to raising enough on the farm to supply food for home use?—A. I think we had throughout my section of Mississippi about as good a cotton crop as there was anywhere in the United States this year. I think it was better there than almost anywhere else. Our crop was made with less money than ever. We made that with the idea that we were only going to get 5 cents. Our cotton hands and all labor was furnished upon the idea that we should have to sell the crop at about 5 cents. Some of my own laborers came in and bought a year's supply with a bale of cotton; food was cheap; flour was not high; meat was—well, I do not know; we bought meat mighty cheap, and we did not give them much in the way of luxuries, and the result was when that went we found that we had a crop that was paying us from 6¢ up to 9 cents that we expected to sell it at 5 cents, and the result was there was a somewhat prosperous condition with us.

Q. (By Mr. RATCHFORD.) Do you sell your cotton direct to the manufacturers?—A. No, sir.

Q. It is sold to the middleman or agent, is it?—A. The cotton is now generally sold to exporters. No, sir. It goes to New Orleans. We sell at home to anybody who will come and buy. Sometimes the mills will send a man to these interior towns and buy cotton and ship directly to the mills. Sometimes it is shipped here to these cotton factors.

Q. Is it sometimes sold to agents or middlemen?—A. Yes.

Q. (By Mr. SMYTH.) You sell to the highest bidder?—A. We sell to the man who gives the most money for it.

Q. You are not interested in what he does with it?—A. No, sir.

Q. On this share system does the landlord settle with his tenant at a certain period of the year and then take the crop and dispose of it later?—A. Some of them do. I never do that. I sell my crop as soon as I get it and settle up with my laborers, but some of them do the other way. They will pay the laborer market prices for the cotton.

Q. And either hold or sell it?—A. Either hold or sell it. I have never held any cotton—never did in my life.

Q. You are not getting 9 cents?—A. I got 9 cents for some of it because I could not get rid of it any sooner.

Q. (By Senator KYLE.) The rule is, you think, to get as good prices at the beginning of the season?—A. Yes.

Q. (By Mr. SMYTH.) Are we to understand that the conditions in Mississippi are better?—A. Than they have been for several years. I would not say ever, because when we got 20 and 25 cents a pound we did very nicely by raising it. We are paying a pretty high proportion now on all sorts of supplies for the advance in prices.

Q. But still there is a general improvement?—A. Yes; I think so. I do not think anybody will deny that proposition.

Q. (By Mr. RATCHFORD.) Where the farm labor is paid by the month, are his wages advanced in any proportion to the advance in cotton and the necessities of life?—A. I do not think so. I do not know about that. I do not know of anybody working for wages.

Q. (By Mr. SMYTH.) All working on the share system?—A. All working on the share system.

Q. (By Mr. RATCHFORD.) I understood you to say a little earlier in your testimony that they received from \$6 to \$15 a month.—A. Yes.

Q. (By Mr. SMYTH.) That is not generally done?—A. No, sir; it is very rarely that you find men working for wages on the farm. That is my observation about it.

(Testimony closed.)

MEMPHIS, TENN., March 22, 1900.

TESTIMONY OF MR. J. R. GODWIN,

Planter, Memphis, Tenn.

The subcommission of the United States Industrial Commission met at the Peabody Hotel at 10.07 a. m., Senator Kyle presiding. Mr. J. R. Godwin, planter, Memphis, Tenn., was introduced as a witness at 11.22 a. m., and, being duly sworn, testified as follows:

Q. (By Senator KYLE.) You may give your name, address, and vocation.—A. J. R. Godwin, Memphis. I will have to give my vocation as a farmer now.

Q. (By Mr. SMYTH.) Where do you live?—A. My home is out 7 miles from the city. I am really living here at the hotel now.

Q. You live in Tennessee?—A. Yes; I live in Tennessee.

Q. What do you plant—cotton? A.—Well, I do not plant cotton for my own crop; I am running a stock farm out there, and my surplus land, what I don't want to cultivate in corn and hay and grass, I rent out to tenants, and the bulk of that is planted in cotton.

Q. How many tenants have you?—A. I think I have about 18.

Q. (By Mr. RATCHFORD.) How many acres of land?—A. About 1,600 acres.

Q. (By Mr. SMYTH.) How much land do these tenants cultivate to the family?—A. Well, they cultivate from 25 to 50 acres.

Q. How many acres to the plow?—A. Well, I can not tell you so much about the plow as I could about mules—that is, 1 and 2 mule crop. A man that cultivates from 20 to 25 acres will have 1 plow animal. If they cultivate 40 to 50 acres they have 2 plow animals.

Q. How many acres of cotton to the plow?—A. Well, I say about 15 acres.

Q. What will that land yield?—A. We calculate an average of about a bale to 8 acres.

Q. (By Senator KYLE.) Where is your land located?—A. About 7 miles east of the city, in Shelby County. It is on the Wolf River.

Q. Not as rich as the Yazoo bottom?—A. Not quite. I have some land that will produce as much as the Delta.

Q. (By Mr. SMYTH.) You plant cotton in the bottom lands?—A. Yes, and on the hills, too; a portion of the land on the bottom and a portion on the hills.

Q. You rent land to tenants on shares?—A. No, sir, I rent for cotton; never rent any other way.

Q. Is that cotton land based on the acre?—A. Yes; it is based on the acre or on the place. If I have a place of 20 or 25 acres, and the character of the land is pretty good, they pay me 2 bales of cotton, and if it is 40 or 50 acres of pretty good land they pay me 4 bales of cotton. I have 1 tenant there that has about seventy-five acres of land; it is pretty fine land, but he only pays 4 bales of cotton. It varies according to the character of the land that they rent.

Q. (By Mr. RATCHFORD.) In your case, then, you do not supply the implements or materials with which to work the farm; the tenant supplies it, does he?—A. Yes; they supply everything.

Q. You supply the houses to live in?—A. Yes.

Q. (By Mr. SMYTH.) And firewood?—A. Free water and free wood; all the wood they want. Of course they have to cut the wood and haul it. They have acres of timber land where they get an abundant supply of fuel.

Q. Now, how do they get advances? How do they supply themselves for the coming year?—A. Some of them have credit at the stores. Some of them have credit in the city. They come here and get what supplies they need. I prefer that, if they can do it.

Q. They pay in the fall after the crop is gathered?—A. Yes. Of course the law of Tennessee gives me a lien on the crops for renting to them, and they have credit where they can get it and get the supplies elsewhere. Of course it gives me less trouble. I only have to collect the rent then.

Q. You generally do not waive the lien?—A. Rather than waive the lien I prefer to furnish the actual necessities of life—that is, I will furnish them meat and meal while they are at work on the crop. Then there is a great deal of work on the place that I pay for.

Q. You hire hands by the month to do that work?—A. No; mostly by the day. I have most of that work done by tenants on the place.

Q. That is, on the stock?—A. Yes; we have corn and hay crops.

Q. (By Mr. RATCHFORD.) What rate per day?—A. Fifty cents.

Q. And this 50-cent-per-day labor finds itself, does it?—A. Yes.

Q. (By Mr. SMYTH.) Mostly colored?—A. All colored. I have no white labor on the place except the superintendent. I have 2 white men there, 1 to look after the dairy business and 1 for the general business of the plantation. But my plan with those tenants is first to let them supply themselves, if they can do it, over here or at some of the neighboring stores. If they say they can not do it, then I furnish them all the absolute necessities. I say to them, "Now, if you have time on your crop to give to work for me I will pay you money every Saturday night, and you can buy what you want to with it." By that means their accounts are very small, and when the crop is made they have a very small account with me, which I want. I do not keep supplies. I do not keep any store. I do not want to furnish anything; do not want to sell anything at all if I can avoid it. I have to sell a plow horse or mule occasionally, but my plan is, if I can, to get a tenant who can supply himself and have his own team and farming utensils. That is what I like.

Q. When the crop is gathered, do they sell enough to pay you your rent?—A. I take the rent in cotton, and they settle the bill they have at the cotton gin and then pay me the rest.

Q. The balance of the crop they sell?—A. Yes; the balance I have nothing to do with.

Q. (By Senator KYLE.) Have they their own gin?—A. There is a gin in the neighborhood.

Q. (By Mr. RATCHFORD.) Is that system more advantageous to the farm laborer than the system of furnishing provisions, or crop sharing, for instance?—A. I like it better. I think there is a little more profit in working on shares. I think it is a little more profitable to me, but it is a great deal more trouble.

Q. (By Mr. SMYTH.) You mean the share system is more profitable?—A. Yes; I think the share system is more profitable to me, but it is a great deal more trouble. I either have to look after it myself or have my man.

Q. (By Mr. RATCHFORD.) You say the share system is more profitable to you. I do not understand that you practice the share system?—A. I say it would be. I have practiced it; some years ago I practiced it. From that experience I may state that it would pay me; certainly when cotton is at the present price, it would

pay me better to work on shares than to rent my land, but it gives me much less trouble to rent it.

Q. From that, then the commission may infer that the system practiced by you is more desirable to farm laborers than other systems?—A. Yes; I think so, yes. I think this country is going to come—people who own plantations are coming—to the tenant system. What I want is to get the best tenants I can get on my place. I am building good houses, supplying them with the best water I can get there—usually good well water, good pure freestone water.

Q. (By Senator KYLE.) What do they have in the way of home comforts, as a rule?—A. It depends a good deal on the tenant. I have some tenants there that I am surprised, in riding around the place, to see the little crop of tobacco, and Irish potatoes, and sweet potatoes; and they have 2 or 3 hogs.

Q. And they have vegetable gardens?—A. Yes; they raise not a great variety of vegetables, because, as a rule, colored people do not care for vegetables.

Q. Poultry, of course?—A. Yes; they raise chickens and geese, and most of them have 1 or 2 cows. Then, again, you may go to a place where you do not find anything.

Q. (By Mr. RATCHFORD.) Their pasture is free, is it?—A. Yes.

Q. Their garden spot consists of how much?—A. Of about half an acre; from quarter to half an acre.

Q. That is also free?—A. That is also free, and I furnish them the timber and nails to put the paling around the garden; but I am sorry to say they very often burn it in the winter.

Q. And your profits from the land consists of the 3 bales of cotton, as described previously in your testimony, for a farm of 40 or 50 acres?—A. Twenty-five acres, 2 bales, and 40 or 50 acres, according to the character of the land, 4 bales of 500 pounds weight.

Q. (By Senator KYLE.) At the end of the season do they get out even, as a rule?—A. Yes; they do on my place. This last year they have made money.

Q. Are they compelled to sell the crop immediately on harvesting it?—A. I do not think so.

Q. They can hold it, some of them, if they choose to, for higher prices?—A. Yes. I had one tenant who sold the last bale, I think, last week. They, of course, are very much like other people about that. A great many white people, not pressed for money, as Mr. Kyle told you, will take the cotton to market and sell it. They do not care to take the risk of having it about home. They know about the cost of cotton, and they sell as soon as it comes in.

Q. (By Mr. RATCHFORD.) Do you ever buy cotton crops?—A. No, sir; very rarely. I have sometimes bought a bale of cotton if I had some interest in it and they come and insist on my buying it; but I do not like to do it, because it is hard to arrive at. In all of these arrangements with labor we guarantee that the laborer will have good treatment, as labor is not so plentiful, and the best labor is somewhat difficult to get on all these places, even as near as I am to Memphis. It is difficult to get good tenants even where I am.

Q. (By Senator KYLE.) Colored tenants?—A. Yes.

Q. You never had white tenants?—A. I never had white tenants.

Q. Have you ever had an influx of colored tenants from other States?—A. We never have had here. They do not come in here, unless they may come across Mississippi. We are near the Mississippi line, and they come across sometimes, I think, from the northern portion of Mississippi; but the labor here in the city, you know, is our best labor. Young, strong men come here; they can get better pay here than we can afford to pay them on the farm. We get the old men and the boys and the women and the children.

Q. The school facilities are the same as in Mississippi, are they? What are the school laws of Tennessee?—A. I think the school laws are very nearly the same as in Mississippi, but I am not positive on that.

A. Are colored schools provided?—A. Yes, colored schools are provided, but I do not see much interest taken in them. I do not think, out of the 15 or 18 families on my place, children from more than 3 or 4 families attend school any time during the year.

Q. They have the privilege if they want to?—A. Yes; they have schools.

Q. Four or five months in a year?—A. I think they have schools five or six months.

Q. Taught by colored teachers?—A. Yes.

Q. Do the children as a rule engage in farm work?—A. Well, in the spring, at what we call chopping cotton, after cotton comes up, and next cultivating; women and children work until the hoe work is done; they do the hoe work mainly of the cotton, and then they do not do anything else. There is no other work they can

do then until the cotton matures and is ready to pick in the fall; say about the middle of September they commence picking cotton, and then they work until the cotton crop is picked out.

Q. Then the work is light on the farm?—A. Yes; they do not hurt themselves, white children or black, either. They do not need any law to keep them from work.

Q. Do you have a disposition among them here to acquire land in fee?—A. I do not know of but one man in my own country out there who owns land.

Q. Why is this; no desire on the part of colored people to own land?—A. I suppose they would take the land if you would give it to them, but they do not seem to do it; they do not seem to purchase land.

Q. (By Mr. SMYTH.) Is there any objection to selling them land if they were willing and able to pay for it?—A. Well, I can not tell you that. I would not sell any part of my tract of land for them to settle on. I may say that very frankly?

Q. (By Mr. RATCHFORD.) Will you sell it to the white man?—A. No, sir; I do not care about breaking it and cutting it up unless I should cut it up and sell all.

Q. If you had a single farm and wanted to dispose of it you would as soon sell to one as to the other?—A. I think so, unless there was some local objection to it; unless there was some tangible reason in the neighborhood why I should not sell to a colored man; but as a rule my information is that these, where they own their own land, make better citizens than where they do not.

Q. (By Mr. SMYTH.) More conservative?—A. Yes; do not get into trouble with the neighbors as frequently as colored people who do not own land and are ready to move at any time.

Q. (By Mr. RATCHFORD.) Do the colored farmers as a rule work for less money where they work by the day or month than the white man?—A. I think not, sir. There are so few white men who work out in my country that I am not well prepared to answer that.

Q. What are your principal reasons for employing colored men exclusively?—A. Well, the class of white men that offer for hire out there as a rule are a very sorry class of men.

Q. You employ colored men because you believe them superior on the farm?—A. I think they get along better working together. Now, I am running a dairy out there; about 75 cows. I have 3 men that milk and do nothing else, and occasionally I have 4 men. I have been trying for a year and a half to get a white man to take charge of that and look after it and assist in milking, and I brought 2 men from Nashville, but I could not get men to fill the place.

Q. What wages do you offer for such men?—A. Thirty dollars a month.

Q. And found?—A. No, sir. I have homes—I have got a free house, a very comfortable house—for him to live in; free fuel and everything of that kind. He furnishes his own provisions.

Q. (By Senator KYLE.) Now tell us something about the cost of growing cotton, and how much the producer gets out of it.—A. I have figured it time and again. I never did figure to my own satisfaction very clearly, but in my country I figure it costs me \$5 an acre to cultivate cotton. That is, the cultivation of it from the time you commence plowing, breaking your land, until the cotton is laid by in July or August.

Q. (By Mr. RATCHFORD.) Costs \$5 an acre? Is that based upon the present rate of wages paid to farm labor?—A. Yes.

Q. (By Senator KYLE.) Five dollars an acre for cultivation? Now, how about planting and picking?—A. In this cultivation I figure planting; I figure everything; I think \$5 an acre will pay for the seed and pay for all tillage of the soil from the time you commence the preparation.

Q. Up to the time of picking?—A. Up to the time of picking.

Q. (By Mr. RATCHFORD.) And including picking?—A. No, sir.

Q. (By Senator KYLE.) How much is that?—A. The average price of picking out there is 50 cents a hundred. We calculate \$8 a bale for picking 1,600 pounds of seed cotton.

Q. Fifty cents a hundred?—A. Yes, sir.

Q. How much to the acre?—A. In these uplands about 3 acres to the bale. Some land will make a half bale to the acre, but the average of Shelby County upland will require 3 acres to the bale.

Q. (By Mr. RATCHFORD.) That would increase the cost of raising cotton about \$2.50 in addition to the \$5 for cultivation, would it not?—A. You mean the rent of the land?

Q. (By Senator KYLE.) The picking is how much an acre?—A. The picking, we calculate that by the 100 pounds. They pick out the cotton, and we weigh

it and we pay them by the 100 pounds—50 cents for 100 pounds of cotton in the seed.

Q. (By Mr. SMYTH.) One-third of that will make lint?—A. Not quite. We calculate 1,600 pounds of seed cotton to make one bale. That would be 1,100 pounds of seed and 500 pounds of lint; sometimes it will take a third.

Q. (By Mr. RATCHFORD.) How many pounds of seed cotton to the acre? You pay 50 cents a hundred for picking seed cotton; how many hundred pounds of seed cotton to the acre?—A. About one-third of 1,600—533 pounds of seed cotton to the acre.

Q. At 50 cents a hundred that would be \$2.66 to be added to the \$5 an acre, cost of cultivation, making \$7.66 the cost to raise a crop and pick it.

(No answer.)

Q. (By Senator KYLE.) It has to be ginned after that?—A. Yes.

Q. What is the cost of ginning?—A. The customary price, if I do not furnish the bagging and ties, is \$2.50 a bale—one-third of that to the acre.

Q. Eighty-three and one-third cents more?—A. Yes, sir.

Q. That would be \$8.50 an acre?—A. I think you may add to that—you may make that \$9 to cover the hauling of the cotton. You have to haul it from the field; furnish a team and driver, and if you have many pickers you have to send a wagon to weigh the cotton, and in all probability you have to haul it again to the gin.

Q. It is about another dollar?—A. I think so.

Q. That would be \$9.50?—A. Make it \$9.50 an acre.

Q. That is the net cost?—A. Yes.

Q. That does not include the expense of horse feed?—A. Yes, sir; I think it does the way I figure it. I figure by the day's work.

Q. How much do you get off the acre?—A. We get one-third of a bale.

Q. That is 177 pounds of lint cotton for the acre, based on 1,600 pounds of seed cotton to 3 acres?—A. That is right.

Q. That would give the cost per pound, five and a fraction cents. You have about the same as Mr. Kyle gave us as his estimate?—A. It will do that. I have figured a hundred times in the last few years.

Q. (By Mr. RATCHFORD.) Then there is the seed. You sell the seed?—A. Yes, sir; we sell the seed.

Q. (By Mr. SMYTH.) At what price do you sell the seed?—A. At an average of 20 cents a bushel.

Q. Then on an acre of land on which you raised 533 pounds of seed cotton there is 177 pounds of lint and 356 pounds of seed; and allowing 33 pounds to the bushel of seed, at 20 cents a bushel it would net \$3.40 per acre for seed; and deducting this from the cost of cultivating the acre in cotton, which you said is \$9.50, it would leave \$7.10 as the cost of raising of 177 pounds of lint cotton to the acre, or an average cost of 4 cents per pound. But, I understand, in this calculation you have allowed nothing as interest on the investment or rent of land?—A. Yes.

Q. Now, in the delta district where cotton is raised about a bale to the acre, or 500 pounds of lint to the acre instead of 177, and where the yield of seed is greater, the cost of raising that lint, I suppose, is lower than it is in the hill country from which we have made this calculation?—A. Yes, sir; that is so. I have never had any experience in growing cotton in the delta, but I have had a great deal of experience with people that do grow it there. I was 20 years here in the cotton commission business.

Q. It costs less to raise cotton per pound in the delta than in the hill country?—A. I think, unquestionably.

Q. Therefore if 4 cents is a fair average of the cost of raising cotton in the hill country, without taking into consideration the rent of the land, it is less than 4 cents to raise it in the delta?—A. I would say so. We have always figured this way. There is a world of extravagance about that delta country that we do not have in the hill country. It seems to cost the people more to live. Whether they pay the labor higher prices—I think they do some—or in some way or other it costs more to run a plantation than on the hill.

Q. If men are employed on the share system, they do not pay more, but they get more because the profit is larger?—A. Yes, sir; and they spend more.

Q. Does the delta cotton sell for any higher price than the cotton raised in the hill country?—A. Yes, sir; it is longer staple and better export cotton.

Q. How much higher?—A. From one-half to three-fourths cent. You have a gentleman coming before you who is a cotton buyer here.

Q. (By Senator KYLE.) Tell us something about the average price of cotton for the last 4 or 5 years.—A. I do not remember the figures.

Q. What did you get as a grower?—A. I got about the average price, because I

sold my cotton as I got it. If the man working on shares came in with 2 bales of cotton, I could not get a satisfactory settlement without sending and selling it.

Q. You sold last fall?—A. Yes, sir.

Q. What did you get?—A. I got 6½ cents for the first I sold and 7½ cents for the last.

Q. The year before what did you get?—A. I got an average, I think, of about 5½ cents.

Q. That is for 1898 cotton?—A. Yes.

Q. How about 1897?—A. For 1897, about the same price.

Q. Ranged about the same for several years?—A. No; only 2 years. Prior to that, in 1896 it was higher, and in 1895 it was still higher than in 1896, because it was a smaller crop.

Q. So it has not fallen any one year to the cost of production?—A. No, sir.

Q. It has left you a little margin each year between the cost and the selling price?—A. I think so.

Q. You think you could afford to raise cotton at 6 cents, if you were assured that price?—A. It would make a reasonable rent for my land at 6 cents. I have not pretended to try to cultivate cotton with hired labor for the last 4 years. Four years ago I did a little, but I have since abandoned it altogether. You can afford to cultivate cotton with hired labor and sell it at 5 or 5½ cents.

Q. You think the best system is the share system?—A. I think the best is the tenant system; better for the tenant and better for the landlord.

Q. You think it should be generally adopted?—A. I think so. I do not think there is any real sense in any other system. One reason I say that is this: You mix up less with the people when you rent the land than on shares. If you rent on the share system, you undertake a supervision of cultivating the crop, and you watch how they are managing it; they feel as if they are partners in it, and it sometimes brings up friction. They feel as if they are going to make a good crop and ought not to be interfered with, and you feel they are not doing it just to suit you. You are more likely to get up friction on either side than when you rent the land, and they know just what they have to pay and you know what to expect. All you know about is to see that they do not abuse your land or allow it to wash away, and that is a small thing. If you treat a tenant right and he wants to stay on the place, he will cheerfully do what you want him to do. If he is not a good tenant and is worthless, the only remedy is to get rid of him at the end of the year. I have no trouble. I have not been inside the fields of some of my tenants in growing season for 5 years. I ride along the road and if I see them I say "Good morning." That is all I have to do with them until they bring their rent in. I have other tenants that I have to look after and see whether they are going to make the rent and take care of the ground and the family. I do not want a tenant on my place that will not take care of his family pretty well.

Q. Under your tenant system you have families who are able to save a neat little surplus and take care of their families in good circumstances?—A. I do not know whether "good circumstances" would express it, but they supply them with food and shoes and clothing and keep them comfortable. I should say they are in a condition to keep their families comfortable.

Q. As if they were laborers on the street in cities?—A. I think so. When they are in the city they get more pay, but they have to pay for everything in the world that they consume, fuel and water and everything else, while in the country they do not pay for anything of that kind.

Q. Do you know anything about the manufacture of cotton? Have you manufacturers of cotton in Tennessee?—A. We have one factory here, which has been very unfortunate. It has been a failure most of the time, and the investors in it have lost a good deal of money. I never was interested in it.

Q. Not running now?—A. No.

Q. (By Mr. SMYTH.) What was the cause of the trouble?—A. I think they located it wrong; away over where they had to cart fuel and everything, and I do not think the management was as good as it ought to have been. They had a gentleman here who had no experience in cotton spinning—working that particular class of labor—and they had to educate the men in the first place to manage it. That is a bad scheme, to invest capital in educating men to manage capital.

Q. The labor was all white?—A. Yes, sir; they never attempted to work colored help.

Q. From this locality?—A. No, sir; I think they brought it from elsewhere. I talked with the superintendent, and he told me he was bringing labor from other localities where they had more or less training in that particular kind of labor.

Q. How long has the mill been shut down?—A. I think it has not been running

for the last 2 or 3 years. I really do not know how long it has been shut down—6 or 8 years. My judgment is it was altogether the fault of the management. If the mill had been properly located out here on the railroad where they could have had switching facilities—

Q. (Interrupting.) They used coal?—A. Yes, sir. If they had a switch so they could run the coal right up to the boiler room and had the raw material run right up to the mill without carting, I think it would have been a success, with average intelligence and managed by some person who had had experience and was educated in that industry.

Q. How many hands did it employ when running?—A. I do not know how many.

Q. (By Senator KYLE.) Where do you sell your cotton?—A. Here.

Q. To whom?—A. I could not tell you that. I send it here to cotton factors, commission merchants, and they sell it sometimes to one and sometimes to another.

Q. Where do they sell as a rule?—A. I think they sell a portion to Eastern spinners and a portion to exporters.

Q. (By Mr. SMYTH.) How many bales are sold here?—A. About 675,000 bales brought here last year. I am not positive I am exactly correct in that.

Q. That naturally brings a large number of buyers?—A. Yes.

Q. So there is every competition in the sale of cotton?—A. Yes.

Q. (By Senator KYLE.) What has been the average selling price of these factors?—A. For what time?

Q. This past winter and spring.—A. I think it opened here at about 6 cents.

Q. Last fall?—A. Last fall; yes. It has gradually increased in value until now I think they are getting it at 9 $\frac{1}{8}$ —middling cotton.

Q. (By Mr. SMYTH.) Good middling would be worth about what?—A. About 9 $\frac{1}{8}$ or 9 $\frac{1}{4}$.

Q. (By Senator KYLE.) What does the commissioner usually charge for selling cotton?—A. About 2 $\frac{1}{2}$ per cent, \$1.25 for a 500-pound bale. For a bale that would bring \$50 the commission man would get \$1.25, in round figures.

Q. (By Mr. SMYTH.) Could cotton be sold here by the farmer without employing commission merchants?—A. Oh, yes.

Q. Sold on the street?—A. Yes, sir.

Q. Buyers will bid right off the street?—A. Yes, sir.

Q. (By Senator KYLE.) Get enough for a carload almost any time?—A. I should think so; yes. They rarely do that. The cotton bought on the street here is as a rule bought by people who do nothing else but that, and they will take the cotton and put it in a warehouse; and sample it regularly and put it on some factor's table to sell to the consumer. That is the way it was done when I was here 6 or 7 years ago. They buy a little under the market. If a man sells off the wagon he expects to sell at one-sixteenth or one-eighth less than if he turned it over to the factor and went into the warehouse and let the factor have time to sell on the market. The factor sells to your advantage. He sells to people who can pay full price to get what they want. The man who buys on the street will usually get 40 to 50 bales together and put them on the factor's table and sell to the exporter or the agent of the eastern spinner or somebody who buys in larger quantities.

(Testimony closed.)

MEMPHIS, TENN., March 22, 1900.

TESTIMONY OF MR. E. W. PORTER,

Cotton Broker, Memphis, Tenn.

The subcommission of the United States Industrial Commission met in the parlors of the Peabody Hotel at 10.07 a. m., Senator Kyle presiding. Mr. E. W. Porter was introduced as a witness at 12.12 p. m., and, being first duly sworn, testified as follows:

Q. (By Senator KYLE.) You may give your full name and post-office address.—A. E. W. Porter, Memphis, Tenn.

Q. What is your business?—A. Cotton broker.

Q. Will you tell us something about the cotton business you are connected with? You are a broker. Have you been employed as such many years?—A. My business is buying cotton here for shipment to other points.

Q. You buy from farmers?—A. From factors almost entirely. They are the commission merchants, you understand, and I buy from them for the consumer.

Q. (By Mr. SMYTH.) You do not buy from the street?—A. No; I would, but it is more trouble.

Q. (By Senator KYLE.) The farmer sells to the factor?—A. He ships to the factor for sale on commission; the factor takes the samples and spreads them out on his table in lots, and buy by sample from him.

Q. Your business is that of broker?—A. I buy here and sell to mills in the East and in Europe.

Q. The advantage, then, to the farmer selling to the factor is, he bunches it in large quantities?—A. Naturally.

Q. You have orders for 500 or 1,000 or 5,000 bales, and you can take it in large quantities from the factor?—A. Exactly.

Q. You prefer doing that to buying at retail from the farmer?—A. Yes.

Q. And he reaps an advantage in getting a larger price for the load?—A. Yes.

Q. Then it is an advantage to the farmer to employ the factor?—A. I think so; beyond question.

Q. So, if a farmer has only 1 or 2 bales, he may be able to consolidate it into a 500-bale lot?—A. Yes.

Q. You buy more than you would do in picking up 5 or 10 bales here and there?—A. You understand the situation as well as I do. That is exactly right.

Q. Where do you find a market?—A. We find a market in all the cotton-spinning sections of the world—all through Massachusetts, Rhode Island, Connecticut, Canada, Liverpool, on the Continent, and we would have a great outlet for cotton over in North and South Carolina if it were not for the prohibitive freight rates.

Q. (By Mr. SMYTH.) Tell us about that—about the Carolinas and Georgia.—A. The freight rates are 59 cents a hundred.

Q. What is it to Lowell?—A. 55½ cents.

Q. So it actually costs more to transport to the Southern than to the Northern mills?—A. I have seen the time when I could send cotton right through Charlotte, N. C., and export to Liverpool for 42 cents when it would cost 59 cents to stop in Charlotte.

Q. (By Senator KYLE.) You mean 42 cents to Liverpool from here?—A. Yes.

Q. (By Mr. SMYTH.) What point of shipment? Pinners Point?—A. Pinners Point.

Q. Shipped from Norfolk?—A. Shipped from Norfolk.

Q. (By Senator KYLE.) How do you explain that?—A. I do not know how, but the Liverpool rate is competitive and the rate to these other points is not.

Q. If you shipped to Carolina points it would be entirely local over the Southern Railway?—A. Yes, sir. And we have here a physical division of the railroads which makes the rate here noncompetitive on everything except export, where the ocean rate comes in.

Q. There would be no reason, then, for not building up business among the Carolina mills if you could get a fair rate of freight?—A. Nothing in the world to prevent it. You see these mills over there have all begun to run on finer numbers of yarn than ever before, and we do ship some cotton there.

Q. Then it would appear the increase in the spinning capacity of the Carolinas is so great that the local supply of cotton is inadequate?—A. Entirely so.

Q. And they have to go abroad for cotton?—A. Yes, sir. We have been working on that freight rate for 2 or 3 years, but have not succeeded in getting it reduced. We can not get any redress at all. For a little while we had it down to 42 cents.

Q. Is there any way you can suggest in which influence can be brought to bear so that the rates of freight to the Carolina mill points can be brought to compare with export or New England rates?—A. The freight bureau has had a good deal of correspondence, and it was suggested by Mr. Culp, of the Southern road, that we get the spinners in the Carolinas to join with us in an effort to have the rates reduced. His idea is that if the pressure comes from that end as well as this, something may be done; but as it is coming from this end only, there is nothing done.

Q. What is the comparative distance between Lowell and the Carolina mills?—A. I would have to guess at that to some extent. I should say probably 1,000 miles from here to the Carolina mills and 1,500 from here to Lowell.

Q. (By Mr. SMYTH.) How far from here to Atlanta?—A. I do not know the distance exactly.

Q. Not over 400?—A. Between 400 and 500.

Q. About 700 to the Carolina mills?—A. I should say about twice that to the Lowell mills.

Q. The rate is 55½ cents to Lowell?—A. Yes.

Q. And 59 cents to Carolina points?—A. Yes, sir; and it is 50½ cents to New York.

Q. You have shipped to Liverpool for 42 cents?—A. Yes, sir; 42 cents, in the past.

Q. (By Senator KYLE.) This concession is made in behalf of Lowell and New England points for what reason?—A. Because the Carolina mills are noncompetitive points, and the cotton has to go out of here over the Southern system—one road only.

Q. If you can suggest any way in which there can be a combined effort between the Carolina spinners and the cotton sellers in Mississippi and Tennessee, we would be glad to have it.—A. If the spinners would join with us in pressure on the Southern Railway to have the rate reduced, and would lay the situation before the road, showing that it is to the interest of the spinner over there as well as of ourselves to have this rate reduced. I think perhaps we could do something. Does not the long and short haul of the interstate-commerce law come in there?

Q. I am afraid that has been locked up by the Supreme Court.—A. I believe we could do that. If the spinners would join with us to bring pressure to bear, we could obtain good results, but I have been working for some two years on it from this end without any satisfaction.

Q. Such an arrangement as that would be of mutual benefit to the raisers in this section as well as the spinners in Carolina?—A. Decidedly, and I should think to the railroad, because they would get so much more cotton to haul.

Q. As it is, the Southern only hauls cotton from this point to Norfolk for shipment?—A. Exactly.

Q. And it would otherwise take some for its local points which it would otherwise not haul?—A. Exactly. I think the freight rate from here to Norfolk is 42 cents, and if you stop it short of Norfolk it is 59 cents, and all we have ever asked is to have the Norfolk rate apply.

Q. Is it not a fact that cotton taken to the Carolina mills would be manufactured into goods and given to the railroad again in that shape as additional freight going out?—A. Yes, sir; certainly.

Q. Have you a fixed brokerage charge?—A. No, sir; we sell on firm offers. For instance, we sell some at 9 cents landed at the mill, and we make what we can out of it.

Q. (By Mr. SMYTH.) Your profit comes in between the price you pay and the price at which you deliver?—A. Yes, exactly.

Q. You have to calculate freight, drayage, and everything?—A. Yes. Competition is so keen that it makes it practically a fixed brokerage.

Q. Is all that cotton shipped from here compressed?—A. All to the East and for export is compressed. When we ship to your country (South Carolina) we frequently ship uncompressed.

Q. Is that because the mills would not receive it?—A. The mills prefer it uncompressed. They will not refuse to receive it, but would rather have it uncompressed.

Q. Still if a fair rate was offered, that might be overcome?—A. Unquestionably.

Q. In compressed cotton you ship about 75 to 85 bales to the car, do you not?—A. It will run hardly that much.

Q. What will it average?—A. They generally figure 50 to the car. It will run from 55 to 60.

Q. I was only speaking from my own personal experience—cotton I bought last year. It ran from 75 to 80 bales. The uncompressed cotton runs about 25?—A. About 25 to the car; yes.

Q. So by compressing the railroad can easily double the amount of tonnage they get in the uncompressed condition?—A. Yes, sir; extra density.

Q. Who pays for that?—A. That is included in the rate. The railroad pays for it.

Q. Seeking the advantage in the less number of cars necessary?—A. They make a rate of 55 cents to Lowell; or compressed they take it at 45¢.

Q. The compressed is about 9¢ cents a hundred lower?—A. It is 10 cents a hundred.

Q. (By Mr. RATCHFORD.) Does it make any difference in the value of the cotton to the mill as to whether it is compressed or not?—A. None whatever.

Q. (By Mr. SMYTH.) Is much cotton sold here in the round-bale shape?—A. Very little.

Q. Do you consider it any advantage, from your standpoint as a broker?—A. No, sir; I consider it a disadvantage.

Q. Is it hard to sample?—A. It is utterly impossible to examine to establish false packing. You can not bore it, you know.

Q. Very hard to extract a sample?—A. Very hard, indeed.

Q. Do your customers object to buying round-bale cotton?—A. Almost without exception. They will not allow us to ship them a bale.

Q. They think it would be harder to handle in the mill?—A. Harder to handle in the mill and more chance of false packing.

Q. What advantage is claimed for it?—A. They claim economy of room and saving of compress. They claim it is put up with sufficient density at the gin to do away with the necessity of compressing again, which is all true; but that is more than offset by the utter impossibility of examining that cotton and seeing whether it is falsely packed or not.

Q. Is it a fact that a higher price is paid for cotton in the round bale than is paid for it in the square bale?—A. They claim so. When I was in Liverpool last spring I asked a firm if they would accept a round bale. They said they would accept it at one-eighth pence off—one-fourth of a cent cheaper; and they claim 45 points on, which would make a difference of nearly three-fourths of a cent.

Q. Their claim that it would sell for 45 points additional is not borne out by experience?—A. Not as far as I have been able to find out.

Q. Do the farmers have any preference about putting it up in round or square bales?—A. I could not answer that; I know so little about the farmers.

Q. How many round bales do you suppose were sent in here this season?—A. I have no way of knowing. It is all bought by one man—the agent of the round-bale people.

Q. As a general practice, brokers avoid it?—A. I think they all have instructions, as I have, to avoid it.

Q. Is there any rate of freight offered by railroad companies in favor of the round bale?—A. I think they make the compress rate of 10 cents less than on the uncompressed bale.

Q. (By Mr. RATCHFORD.) Do you have much difficulty about false packing?—A. We do have more or less; not very serious.

Q. False packing is putting yellow or colored or bad cotton in the center of the bale and good cotton around it, or else putting sand or iron bars or water—A. (Interrupting.) Water is the great trouble. Understand, I do not say that it is done with criminal intent. It may be in some cases and doubtless is. In a great many cases where the cotton is very dry they dampen the gin box to make it hold, and frequently they use very poor judgment in that and get too much water, and it water-packs the bale.

Q. Have you ever had experience where you had reason to think there was criminal intent?—A. Yes, sir.

Q. That leads to reclamation from the customer?—A. We generally catch that here. We bore it and find that here; that is the advantage of the square bale.

Q. You would either reject the bale or claim on the factor?—A. We reject it.

Q. What becomes of the bale when you reject it?—A. If it is water-packed, it is sent to the cotton picker and the water is taken out. If it is a mixed-packed bale, it is sold at a reduced price as such.

Q. It generally sells at the value of the lowest grade?—A. It generally sells at about the price of low middling cotton when mixed-packed.

Q. Memphis is one of the largest shipping points in the South?—A. Yes, sir; the largest inland cotton market in the world.

Q. (By Senator KYLE.) Do you ship via New Orleans?—A. Frequently; by New Orleans, Pensacola, Brunswick, Norfolk, Boston, New York—almost anywhere.

Q. You ship for Liverpool to Norfolk over the cheapest road?—A. We get our rates from the cotton committee, and all the roads will meet that rate. So when the rate is posted you can take your choice of the road.

Q. You have to arrange for the tonnage with the vessel, do you not?—A. Yes, sir; you arrange it here with the road.

Q. They provide that?—A. They provide that.

Q. Were the rates lower this year to the Continent or Liverpool during the fall on account of the slow selling of the crop?—A. They were lower for a little while.

Q. Vessels were waiting for cargo?—A. Yes.

Q. What are your selling rates since last fall?—A. The prices?

Q. Yes.—A. Started in about 6 cents and ran all the way up to 12½ cents, depending on the staple and the condition of the market.

Q. These are the prices at which you sell to Eastern factories?—A. You would add to that about seven-eighths of a cent to get the price in the East.

Q. You are furnishing cotton to the Eastern factories?—A. Yes.

Q. You buy from the factors at 6 cents and sell at 6½ cents?—A. That is what we hope to make; frequently we do not.

Q. About one-eighth of a cent a pound?—A. Yes.

Q. And the factor makes how much?—A. The cotton factor here?

Q. Yes.—A. His commission is $2\frac{1}{4}$ per cent.

Q. (By Mr. SMYTH.) He makes more than the broker?—A. Frequently; his is certain and the broker's is very doubtful. I think we could have better rates if we could do away with the physical division of freight we have here; that does away with any necessity for competition among the freight agents. When the Southern road has as much as it is allowed by the physical division, it has to turn the cotton over to some other road.

Q. That is practically pooling?—A. Absolutely. It is pooling.

Q. Are you in favor of pooling?—A. No, sir. I wish we were able to break it up.

Q. (By Mr. RATCHFORD.) By that do you understand each road is prorated?—A. Yes.

Q. And is allowed its percentage on the cotton freight whether it hauls that cotton or not?—A. That is the exact idea. As I understand it, each road is allowed a certain percentage, and you can readily see how it does away with any competition at all.

Q. You are opposed to it?—A. Yes. We had a lawsuit about it last year, but the supreme court of the State decided against us.

Q. Have you any reason to know whether that is a question of jurisdiction for the Interstate Commerce Commission?—A. I am not sufficiently posted to answer that, but I should think it would be. It is pooling pure and simple.

Q. If not, do you believe it ought to be?—A. Certainly.

Q. (By Mr. SMYTH.) There was an absence of orders for cotton during the fall from the Continent?—A. There was from the Continent and Europe; orders from the East were very liberal in the fall.

Q. That absence of orders tended to keep the market down?—A. Yes.

Q. That is, there was an oversupply for the time being?—A. There was an oversupply, and the result was the domestic spinner got his supply very nearly at the bottom of the market this year.

Q. (By Senator KYLE.) To what do you attribute the high price of cotton this spring?—A. To the short crop.

Q. Nothing else?—A. No.

Q. (By Mr. RATCHFORD.) You speak of a cotton committee. Is this cotton committee representing the carrying companies?—A. Yes, sir.

Q. Appointed by the carrying companies?—A. As I understand it, they have a secretary appointed and paid by the different railroads, and he promulgates all the cotton rates.

Q. (By Mr. SMYTH.) You have nothing to say about the rate?—A. No, sir. These railroads, as I understand it, get telegrams in the morning naming the rates to Liverpool, say. If the Southern has a lower rate they put that rate in to the committee first and then to the shipper, and that cotton committee promulgates this rate, and I can go and tender the cotton to the Illinois Central or any other road and get the same rate. Every bill of lading—a copy of it—must be filed with the cotton committee.

Q. (By Mr. RATCHFORD.) Would you recommend an extension of the powers of the Interstate Commerce Commission in any other respect?—A. It is the only one I am familiar with.

Q. (By Mr. SMYTH.) Would you favor giving them power to fix rates and classifications?—A. At first blush, I think I would.

Q. The railroads, as it is now, submit their rates to the Interstate Commerce Commission, and if the commission objects to a rate, says it is unfair, it remains in force until the courts pass on it, and if they are favorable to the contention of the Interstate Commission, then the railroad would have to make the rate unless it appeals and keeps up the fight in the courts. Now, would it be better for the Interstate Commerce Commission to have the authority to institute the rates which are to be in force from a day fixed and then let the appeal come from the railroad company?—A. I hardly know how to answer that; it had not occurred to me before. I would have to think about that before answering it.

Q. You see in one case the Interstate Commerce Commission would promulgate a rate that would go into effect and be in operation until the courts decided it was too low or unfair. As it is to-day, the railroads inaugurate the rate and the Interstate Commerce Commission has to appeal to the courts to annul it, and the rate is in force while the appeal is pending.—A. I think all that could be arranged if the Interstate Commerce Commission had the authority—if they do not have it now—to handle matters just exactly like this here.

Q. (By Mr. RATCHFORD.) You believe in giving them greater powers as a general proposition?—A. I do. Since you asked the question a while ago, whether or

Not we could suggest some plan by which we could get the rates reduced to the Carolinas, I believe if we could get a committee of spinners there to meet a representative body from the buyers and shippers here and go to Washington and lay this matter before Mr. Culp we might accomplish something.
(Testimony closed.)

MEMPHIS, TENN., *March 22, 1900.*

TESTIMONY OF MR. F. M. NORFLEET,

Cotton Factor, Memphis, Tenn.

The subcommission of the United States Industrial Commission met at the Peabody Hotel at 10.07 a. m., Senator Kyle presiding. Mr. F. M. Norfleet, cotton factor, was introduced as a witness at 12.37 p. m., and, being duly sworn, testified as follows:

Q. (By Senator KYLE.) State your full name and address.—A. F. M. Norfleet, Memphis, Tenn.

Q. And also your vocation.—A. I am a cotton factor; that means, we are cotton commission merchants, and sell cotton.

Q. You buy directly from the farmer?—A. I am a farmer myself. We do not buy from the farmer. I farm in the Yazoo Basin, and also on the hills of Mississippi.

Q. How long have you been growing cotton?—A. Well, for 30 years.

Q. So you are familiar with prices during all these years?—A. Yes. I have grown it myself on plantations, and have had it grown since I have been in the cotton commission business.

Q. How have prices ranged during the 30 years of your actual experience?—A. They have dropped along down from 12 cents, perhaps, as a maximum price—in 30 years, you mean?

Q. Yes; in 30 years.—A. I thought you had referred to a later period. Well, going way back to 1870, cotton has gone, I should say, from 16 to 20 cents down to 4.

Q. Down to 4?—A. Yes.

Q. Of course those were days following the war?—A. The high price following the war, in 1870.

Q. How about the cost of growing during these years; that is, when cotton was very high?—A. The cost of producing cotton has been reduced very materially in the later years. Our methods of cultivation are better, and the price of labor has fallen very materially since the war.

Q. During those high-priced days, when cotton was selling from 25 to 35 cents a pound, did you have to pay materially higher for labor?—A. Yes. We paid from \$1 to \$1.50 a day for labor. We paid from \$200 to \$250 for mules. Lands were worth from \$15 to \$25 an acre.

Q. So that you really would not make any more money than now, when cotton is selling at 8 or 9 cents a pound?—A. No, sir.

Q. (By Mr. RATCHFORD.) You said that the planter and landowner is making as much money now as when cotton was selling at 18 and 20 cents a pound. This has been a very profitable year in the South. Do you not believe that the laborer—farm laborer—should share in that increase? I understand you to say he received \$1 or \$1.50 at that time. Now he receives, when hired by the day or month, in the neighborhood of 50 cents, according to the testimony.—A. In the uplands the price is about 50 cents a day; in the delta about 75 cents, 50 per cent more in the Mississippi bottom for labor than on the hills.

Q. From that, then, it seems that the laborer is not remunerated for his labor in proportion to the remuneration of the landowner?—A. I suppose labor is getting fully as much in proportion. At that time they paid 15 or 18 cents a pound for meat and from \$9 to \$10 a barrel for flour; \$2.50 for a pair of shoes; everything was very high.

Q. Now what is meat worth?—A. Meat is worth about 7 cents a pound now.

Q. (By Senator KYLE.) Flour is worth what?—A. \$3.25 to \$3.50.

Q. (By Mr. RATCHFORD.) You think on the whole the labor is quite as well off, do you?—A. Yes; in fact I think labor is better off now in the South than ever before since the war.

Q. (By Senator KYLE.) Seventy-five cents a day you pay them and furnish the house and land?—A. We furnish everything, yes; all the ordinary farm comforts.

Q. You use negro labor entirely, do you?—A. Yes.

Q. Have you noticed any material improvement in the condition of the negroes since slavery days?—A. I think so. They are getting to be more or less educated. They understand how to transact business better than they did formerly, and are progressing, as far as my opinion goes, very steadily.

Q. Do they show any disposition to accumulate property?—A. Yes; quite a number of them in the Mississippi—in the delta country—are buying lands now.

Q. Buying lands there?—A. Yes; quite a number of them. I have sold a good many places myself to negroes.

Q. How large farms?—A. Well, from 40 to 80 acres.

Q. What do they pay per acre for this land?—A. They usually buy unimproved Mississippi bottom land at a price of about \$6 or \$8 an acre.

Q. Wood lands?—A. Yes.

Q. Clear them themselves?—A. Clear them themselves. They will live on the adjoining plantations and cultivate the improved land, and during the summer after the crops are laid by will clear up and improve their own land.

Q. You sell under mortgage, of course, to these parties?—A. Yes.

Q. What are the terms?—A. Two, 3, 4, 5 years, usually at 6 per cent interest. The Illinois Central, or Yazoo and Mississippi Valley Railroad, acquired, when they bought this system here from Mr. Wilson, about 600,000 acres of land, and they set the pace. They fixed a uniform price at first, about \$6 an acre, and gave about 5 years to pay for it in, in equal payments, 6 per cent interest, and where the white man or colored man was disposed to buy land, he had the privilege of buying from the railroad—their lands were scattered everywhere—or from private citizens who owned land, at about the same price.

Q. What is the down payment in this case?—A. Usually about 10 or 20 per cent.

Q. Farms cost probably \$300?—A. Yes; sometimes there has been a disposition to sell that character of land without any payment down at all, because every blow that was struck with an ax, every move made on the place, improved its condition or value.

Q. And what per cent for deferred payment?—A. Well, say 20 per cent in 4 years, or if it was bought on time, 20 per cent a year for 5 years.

Q. Twenty per cent a year for deferred payments?—A. Yes. On a place worth \$500 perhaps they will collect \$100 cash, for instance; and then for 4 deferred payments they collect \$100 at 6 per cent interest a year.

Q. (Mr. RATCHFORD.) Can a negro farm laborer maintain his family ordinarily on 40 acres?—A. Yes.

Q. On cleared land?—A. Yes; splendidly.

Q. (By Senator KYLE.) Quite a large-sized cotton farm?—A. Yes. They do not cultivate quite as much in the delta as on the hills.

Q. What has been your experience in dealing with those men? Do they pay promptly?—A. Yes.

Q. Some come to own the lands?—A. Yes; quite a number.

Q. But after they possess the land they show a disposition to mortgage it?—A. Well, they are getting more and more careful along those lines—in placing their business, for instance. We have a good many applications for business from that class of trade, but ordinarily we avoid taking any. Our business is mostly with merchants, with what we call large planters, running from 100 bales a year up. They are disposed to find people who they think would not care to traffic any with them in any way, so as to get their places. They are very careful about that.

Q. They own their implements and mules?—A. Yes.

Q. Do they ordinarily own implements and mules in case they are renters on other pieces of land?—A. They get to own them pretty soon. The delta farmers in later years have gotten to sell mules on time. They furnish them a mule, for instance, at \$100 or \$125, and if they can pay for it, all right; and if not they take it back at an agreed rate at the end of the year. The disposition now is to rent land very largely at so much per acre. I think it is likely to prove very injurious to this country, especially the upland section in the South. The tendency is to get rid of the management of the labor, to furnish them cheap stock and cheap utensils and improve as little for them as possible and get rid of the worry. The white people as a result will move into the little villages and stations, towns around; and it seems to me it will be only a few years until the larger part of the upland section of the country, especially this section of the country, will be occupied by negroes. The lands, of course, under their management as tenants, will wash away and wear out, fences go down, improvements become dilapidated. I have regarded that particular feature of the case here as being rather a gloomy one.

Q. (By Mr. SMYTH.) Do you think the leaving of the colored people together and alone so much tends to have bad results among them?—A. Well, I think it is wearing out the country.

Q. I mean their moral and physical condition?—A. I think it has some effect that way.

Q. The negro is very imitative?—A. Yes. They get along pretty well as far as that is concerned. For instance, Mr. Coleman, who owns a large place in Panola County, Miss., bought a little home in Como, a nice little town, to carry his family there, so they might have school facilities and social advantages that they could not have in the country. I said to him: "When your last wheel dropped over the mud sill of your gate, moving your household goods away, I am sure the valuation of your place was lessened \$5 an acre." Well, he said he did not know whether that was the case. I said, "Yes; it is several miles out there, and you are getting to be 40 or 50 years old now, and you are perhaps going for the first year twice a week out to your place, the next year once a week, and the following year once in two weeks, and finally it will be abandoned to the labor on the place, and it will never look like the same place again;" and it will not.

Q. All the white people left?—A. Yes; and they are doing it in thousands and thousands of instances.

Q. (By Senator KYLE.) The negroes are not good managers, then?—A. Not in the way of keeping up repairs.

Q. (By Mr. RATCHFORD.) What is the land worth where it is rented for cash consideration?—A. It is worth from \$2 to \$4 an acre for hill land. Lands on the Mississippi bottom are worth \$3 to \$6 an acre.

Q. (By Mr. SMYTH.) That is, arable lands?—A. Yes. The others do not rent at all except for pasture.

Q. So the rent is fixed simply on cultivation?—A. Yes.

Q. A great deal more land is occupied by the tenant?—A. Yes; he could occupy a quarter section of land and there would not be over 20 acres cultivated, the rest being timber land.

Q. (By Mr. RATCHFORD.) Does he not pay for that indirectly? Is not the value of that added to the value of the land that is workable?—A. It depends on the locality. In the delta it has nothing at all to do with it. There might be 1,000 acres in it of timber lands and it would not affect the 20 acres of open land.

Before we leave the labor question I would like to say that this disposition to rent that the negro has chiefly in this country is due to a desire to have charge of his own affairs without being hindered. That being the most pleasant arrangement for him, is the one he insists on in making his arrangements for the year with his landlord. The landlord himself would prefer the share system. It is the best because then the negroes operate under his supervision and the farm as a rule is kept up better but on account of the scarcity of labor the landlords through this section of the country have to pursue largely whatever plan suits the labor best. There is a scarcity of labor here.

Q. (By Mr. SMYTH.) Has there always been a scarcity of labor?—A. Yes; some.

Q. What has become of labor?—A. Well, you can take my plantation, for instance, in Tunica County, Miss. I suppose there are 150 colored men at work on public works around about the place within a space of 2, 3, or 4 miles.

Q. As mechanics?—A. No, sir; as levee builders and working at various public work.

Q. Common labor?—A. Common labor, but not on the farms.

Q. Have they withdrawn from the farms?—A. Yes; and there is more or less of that kind of work going on throughout this entire section.

Q. Paid better wages?—A. They are paid from \$1.25 to \$1.50 a day.

Q. (By Mr. RATCHFORD.) Is there any form of social organization among the farmers—alliances, for instance; any organization of that kind?—A. No, sir. There are school privileges around where I have been farming which are very good, were they disposed to take advantage of them.

Q. (By Senator KYLE.) Do they show a disposition to attend there?—A. Yes; the farmers all over this section of the country are very much disposed to afford all the school and church facilities they can. For instance, on my place I have helped to build two churches, one Baptist and another Methodist. I am willing to help them to have good buildings, and make them attractive, so that they shall have preaching and school facilities, and so on, and improve their condition as much as possible.

Q. Can you notice a tendency toward thrift among the colored people as a class?—A. Yes; I think they are improving in that respect. Of course, they have not made rapid strides at all. They have been very slow. They are paying debts better and are making more money than they have for years. It has been better

every year; even with the low price of cotton they begin to figure on what they can pay. They are more intelligent in making contracts in their trading.

Q. Now, as as a cotton factor, you buy directly from these farmers?—A. No, sir; we do not buy at all. We advance money and supplies to farmers—to the larger farmers and planters, you may call them—to make their crops.

Q. To white as well as black?—A. We advance to very few colored people, and then they, as a rule, do not come to a market like Memphis to get advances. The colored people trade in their locality.

Q. Is that the custom for years for the white farmer to come to the factor to get money to make crops?—A. Yes; for the last 50 years.

Q. What can you say as to that during the present spring?—A. There has been less demand for help this spring than for 15 years before.

Q. Why is that?—A. On account of the higher prices of cotton.

Q. They made money enough themselves to tide themselves over to make a new crop?—A. Yes.

Q. (By Mr. SMYTH.) Better condition than formerly?—A. Very much. I had a case on my books. I was down in Mississippi Saturday. My bookkeeper reported on my return that a gentleman had called and seemed to be disappointed in not finding me present, and stated that he was anxious to see me. I thought a good deal of his business and was a little worried about it, and on Monday I wrote him a letter that I was very sorry I was not at home, and wanted him to let me know if there was anything I could do for him; I got no answer to my letter. I felt a little bit put out from the way the bookkeeper described his actions in the office on Saturday, so I wrote a letter to a neighbor of his who is very friendly to me, to see him in a day or two and find out if there was anything the matter. I did not want him to slip out of our hands and go somewhere else. This gentleman called on him in his desire to help me out if he could, and learned that he thought us the best people in the world, and had nothing against us. After a few days I had our bookkeeper make out what I call a plantation ledger footing of the accounts from our books showing debits and credits of various parties doing business with us. I got along down to this party's name, and to my surprise, I found about \$3,500 dollars to his credit. Now, I said, I understand what is the matter with that fellow; he has not any more use for us. When he came up he said, I had no particular need to answer your letter. That is just an illustration of the condition of the country. He began by paying perhaps \$2,000 rent, and had commenced on a 3 years' option, and had bought nearly all on credit; I was surprised to find the condition of his account.

Q. Landlord?—A. No, sir; renter.

Q. (By Senator KYLE.) Money in the bank to begin the new year?—A. Money in the bank; yes.

Q. This is the customary method of renting in this section of the country, is it?—A. Of renting. Now, this is a white man I had reference to.

Q. The landowner, landlord, rents to a party who is called a white tenant?—A. Yes.

Q. He subrents to his tenants?—A. Yes. There are different classes of people. You would hardly call men of that sort in a general way tenants. He is a man of means himself. Some own as much as 50 head of mules, and have plenty of money to operate their business on, and still rent land.

Q. (By Mr. SMYTH.) Not own the land?—A. Not own the land.

Q. (By Senator KYLE.) Come to be owners by and by?—A. Sometimes, and sometimes not. We have had parties rent land and pay as high as \$6,500 rent a year.

Q. (By Mr. SMYTH.) Prefer that to owning land?—A. Yes. The lands in the Yazoo Basin are operated pretty largely by parties who rent in that way.

Q. How much cotton does the large farmer make now?—A. Well, the large planter I should say makes to-day about 600 or 700 bales of cotton; 600 bales to 2,500.

Q. A single individual can not make as much as 2,500 bales?—A. Yes.

Q. How many plows would he run?—A. Well, in this vicinity, that is, in the Delta, they will make an average of about 10 or 12 bales of cotton to the mule. I should say to 1,000 bales of cotton they would use something like 70 odd mules; 2,000, 140; in that proportion.

Q. Are there many large planters like that?—A. Quite a good many.

Q. (By Senator KYLE.) What have you to say in regard to taxation; the rates in Mississippi and Tennessee?—A. Well, of course, we always complain of taxation.

Q. (By Mr. SMYTH.) Always too high?—A. Always too high. As a citizen of

Memphis, we have a high rate of taxation here. It is something over 3 per cent—the municipal, State, and county tax.

Q. (By Senator KYLE.) How is it with the agricultural lands?—A. In the Delta we pay about 3 per cent; about 17 mills of that, in the front counties, is levee tax, and the remaining 13 would be State and county tax.

Q. Three per cent on full valuation returned?—A. Three per cent on assessed valuation.

Q. Generally about one-third?—A. The lands are assessed \$8 to \$12 an acre for open land.

Q. Considered about one-third valuation?—A. Well, I expect that is about it in many instances.

Q. About 1 per cent of the real valuation of the land?—A. Yes.

Q. (By Mr. RATCHFORD.) That also applies to this land you speak of being worth \$8 an acre?—A. Yes. Then we pay an acreage tax of 5 cents per acre on the entire acreage.

Q. (By Senator KYLE.) That land is particularly susceptible to overflow?—A. That is all land susceptible to overflow and protected by levee system, and, as I say, we pay in the front counties 17 mills and in the back counties about 12 or 13.

Q. (By Mr. RATCHFORD.) Do I understand you to say you reside in this city?—A. Yes.

Q. Is the burden of tax higher on the farmer of Mississippi than it is in the city?—A. The burden of tax is heavier in that portion of Mississippi subject to overflow.

Q. Than in this city, Memphis, according to the value of the property assessed?—A. I think the assessment would have all to do with that, and I think it is on the same proportion.

Q. (By Mr. SMYTH.) In addition to that State and county tax, you have a city tax to pay?—A. Yes.

Q. A farmer living in the country has no city tax to pay?—A. No.

Q. And your taxes in the city are higher?—A. Yes; about 3 per cent higher.

Q. In the city alone?—A. No; that covers all the taxes, State and county included.

Q. (By Mr. RATCHFORD.) Property is also higher?—A. Yes; property is assessed, I think, on the same basis—say 40 per cent of value, 40 to 60—according to the conscientiousness of the party giving and the particular friendship with the assessor.

Q. Then you do not concur with the claim that has been made by agricultural people in general that they bear a greater burden of taxation than others who own real estate?—A. Well, now, as between parties owning real estate in the country and in towns, I do not think there is any ground particularly for any such claim. I think, however, that the personal property of the agricultural class, as a rule, is more exposed, and that they pay more fully on what they own than the ordinary citizen of the city and those pursuing other occupations.

Q. The advantage that may be taken of our tax system is not in real estate, but rather in personal property?—A. Largely. You can arrive at it and collect tax with much more ease when you see the property.

Q. The farmer can not hide any of his?—A. Yes. It has been my opinion for several years that it would pay the State and our municipalities very much better to fix a very low rate of taxation on personal property, so it would come to the surface and be assessed, and would contribute a certain proportion of the funds necessary to carry on the affairs of the State.

Q. (By Senator KYLE.) Do you know what the cost of raising cotton is? Can you tell us experience in that line as a planter?—A. Yes, I suppose. I can give it to you both from an upland and river standpoint. I am farming both ways. In the Mississippi bottom we pay from \$4 to \$5 an acre to the tenant and the laborer where we work cotton by the acre; that is called the acreage plan of cultivating a crop. That is what the labor gets.

Q. Does that include the seed?—A. That does not include anything but labor. The landlord then furnishes the seed, the team, the implements, and the feed for the team. I have not figured out that lately. It is very easy to get at.

Q. The seed is how much per acre?—A. It is according to the price of seed. The seed now, I suppose, you might figure—

Q. On 30 cents?—A. Yes; something over a bushel of seed to the acre. That, though, is a long ways above the average for seed.

Q. Five dollars for cultivation?—A. Five dollars for cultivation.

Q. How much for the picking?—A. I think you have got along too fast, going to the picking. Don't you want to put the rent of the mule, and the feed of the mule, that goes into the cultivation of the crop, the use of the tools, and so on? They are all figured in addition to the \$5.

Q. How much is that now?—A. Well, we estimate the use of the mule—such mules as we have in the Delta—at \$25 to make a crop.

Q. That is not for the acre?—A. No, sir; they will cultivate about 20 acres.

Q. (By Mr. RATCHFORD.) What items of expense go to make up the \$5?—A. That is what is paid labor.

Q. (By Senator KYLE.) There is 80 cents for the mule?—A. No, sir; more than 80 cents for the mule; that is something over \$1; 20 into 25 gives \$1.25.

Q. A dollar and a quarter for the mule?—A. Yes. Then I should say that the use of the gear and plows we might figure at 50 cents an acre.

Q. Fifty cents an acre?—A. Yes.

Q. Rent of the land?—A. No, sir; not yet, I reckon. We will get through with the mule. Then we usually estimate about 7 bushels of corn per month for the mule.

Q. How many months?—A. Well, now, it is merely a question as to whether you are keeping a larger part of the mules for the cultivation of the cotton, and derive no other benefit from them, or not; if it is purely a matter of cotton, then you have got to feed them 12 months, I should say 75 bushels of corn.

Q. For a mule?—For a mule—to keep him a year.

Q. That is worth what?—A. I would put it at 40 cents.

Q. A bushel?—A. Yes. That is \$30 for the feed.

Q. Thirty dollars for the 20 acres?—A. Yes.

Q. (By Mr. SMYTH.) One dollar and fifty cents?—A. One dollar and fifty cents for the feed of the mule.

Q. (By Senator KYLE.) Now, we have got to what?—A. Now, that mule, of course, eats something besides corn. It is fed hay. I expect we may put that at \$1.60, fodder or hay. Now, then, we have rent of the land.

Q. Yes, how much an acre?—A. I should say \$6 an acre. We might put that at \$5; that would be an average.

Q. Five dollars?—A. Yes.

Q. An acre?—A. Yes.

Q. (By Mr. RATCHFORD.) Can not a mule be used for any other purpose than raising cotton?—A. Yes, and to some extent they are.

Q. (By Senator KYLE.) Now give us the picking.—A. We usually pay 50 cents a hundred for picking.

Q. You figure that at how much?—A. About \$8 a bale.

Q. A bale to the acre?—A. No, it would not make a bale to the acre; a great many acres will, but taking the usual cultivation, I should say two-thirds of a bale to the acre; not over three-quarters.

Q. You pay \$8 for that?—A. No, sir; we pay \$8 a bale. Two-thirds of \$8 will be—

Q. Six dollars?—A. Yes.

Q. Per acre?—A. Yes.

Q. (By Mr. RATCHFORD.) It wouldn't reach \$6.—A. No, sir; not for two-thirds of a bale.

Q. (By Senator KYLE.) About \$6?—A. Yes, in round numbers. The expense of hauling to the gin and handling would be something like \$1 a bale. That would be two-thirds of \$1—66½ cents an acre.

Q. Seventy cents in round numbers.

Q. (By Mr. SMYTH.) Where would that expense come in, provided you had no mule to haul it to the gin?—A. Well, you have got to get somebody to go after it and attend to it. By the time you employ 2 or 3 hands to go with a wagon and get a bale of cotton in the field and weigh it up—

Q. (By Mr. RATCHFORD.) I understand labor is necessary to load and unload it?—A. Yes.

Q. (By Senator KYLE.) Now, ginning and tying it?—A. About \$2.50 a bale; that would be two-thirds of \$2.50 per acre.

Q. That brings it right up to market?—A. Yes.

Q. That is the total cost?—A. Yes.

Q. That makes \$22 an acre?—A. Yes.

Q. As the cost of raising cotton?—A. Two-thirds of a bale.

Q. Raising what?—A. Two-thirds of a bale.

Q. Raising two-thirds of a bale in the Delta region?—A. Yes. Now, then, you want to give yourself credit by selling cotton and seed.

Q. That is very nearly the figures given before—between \$20 and \$25?—A. I should think that figured more than 5 cents per pound for the cotton. Our country can not raise cotton for 5 cents and prosper. My experience is that when our people have to take low prices for cotton their losses are made by failure to make any further improvements on their places; their fences, their houses, their teams, utensils, and everything run down.

Q. (By Mr. RATCHFORD.) What is seed selling for now?—A. About 26 cents now.

Q. (By Senator KYLE.) How many bushels of seed to the acre?—A. Two-thirds of 30 bushels—20 bushels.

Q. Five dollars an acre?—A. Yes, the seed estimate on the plantation. Then you have to haul it to stations, and pay freight—\$1 to \$2 a ton.

Q. That gives exactly 6 cents as the price of raising cotton?—A. Yes; that is what it costs parties renting land and buying feed to raise it. It takes seasons like this past year now to give people in cotton-growing regions enough spare money to reinstate themselves on their places, and there is some of that being done now. It has not been done before to any extent for 15 years in this section.

Q. You have met these men, from time to time, bringing in cotton, and have had time to converse with them?—A. I am actively in connection with it myself.

Q. The men come in to borrow money to make cotton with, and you understand when they come to pay this money back whether they have come out even or not?—A. Oh, yes; our connection with them is very close, so that we are in touch with almost all transactions.

Q. During years when cotton was selling at 5 and 6 cents a pound, what was your observation?—A. We carried over a large balance on our books, accounts not paid.

Q. Not able to get out even?—A. Many times not able to get out even.

Q. Were some able to get out?—A. Yes.

Q. To what do you attribute that?—A. The supply of labor on various plantations has a great deal to do with the successful operation of the place. It has more to do than any other thing, perhaps, connected with the growing of the cotton.

Q. Some farmers will have the help of their own families?—A. They work largely hired and other labor.

Q. (By Mr. RATCHFORD.) Economy in living has something to do with it?—A. The management, of course, at the head of a plantation has all to do with it. A man may have the best management, and if he is unfortunate in securing a supply of labor he can not farm successfully.

Q. (By Mr. SMYTH.) No man can raise 2,500 bales of cotton?—A. Not unless he has very fine ability, and the more capable the man is the better you can afford to have him, and the more successful he is the more you can pay him. I know plantation managers who get as high as \$2,000 a year for their services.

(Testimony closed.)

MEMPHIS, TENN., March 22, 1900.

TESTIMONY OF MR. WILLIAM A. GAGE,

Cotton Commission Merchant, Memphis, Tenn.

The subcommission met in the parlors of the Peabody Hotel at 10.07 a. m., Senator Kyle presiding. Mr. William A. Gage was introduced as a witness at 3.35 p. m., and, being first duly sworn, testified as follows:

Q. (By Senator KYLE.) You may give your name and address.—A. William A. Gage, 300 Front street, Memphis, Tenn.

Q. Your vocation.—A. Cotton commission merchant.

Q. You are president of the cotton exchange in Memphis?—A. Yes, sir.

Q. Your business is that of cotton factor?—A. Yes, sir.

Q. In that way you have dealings with planters and farmers in this district?—A. Yes, sir.

Q. Will you give to the commission some information as to the condition of these farmers, especially their present condition, as compared with 5 or 10 years ago?—A. Owing to the very low price of cotton which has prevailed for the last 3 years, the farmers have not been in what might be termed a satisfactory condition. This year, however, while they did not raise as much as for the past 2 years, the advance in the price has enabled them to realize more net income from the proceeds of the crop.

Q. So their condition financially is better than for the past 3 or 4 years?—A. At this time I think it is better. There is more money in the country and in circulation. People, as a rule, are not asking so early for advances, and are not asking for such large advances as for several years previous to this.

Q. Your customers are mostly white?—A. Nearly all.

Q. Do they nearly all own their land or are a large number renters?—A. Nearly all own their land. We do not do business with renters to any extent unless the landlord waives his rent. In this State rent is a statutory lien on the crop, and unless that is waived the landlord can come in and get the proceeds of the crop—all crops, whether corn, cotton, or any other product of the land—and take priority over a commission merchant or anyone else the renter may be indebted to. Where a man does rent land, and we furnish him, we generally take a mortgage on the crop and whatever live stock he has to aid the waiver of the landlord.

Q. From your business relations with the customers, which I take it are intimate, do you find that many of the landowners are mortgaged?—A. The greater part are mortgaged, I think; some for a small and some for a larger amount.

Q. Some to a dangerous extent?—A. Yes, sir; the mortgage loan companies very frequently find they have loaned too much on a tract of land and have to own it. For that reason there are quite a large number of loan and mortgage companies with agencies in this State that have acquired the ownership of land and are renting it out themselves—in some instances renting it as a matter of business as landowners.

Q. Has the value of land increased in the Memphis district in the last 5 years?—A. A great deal; particularly in Arkansas, Mississippi, and in what we call the bottom land of the hills—we mean rich land, fallow land, creek bottoms.

Q. Are they planted in cotton or corn?—A. Mostly in cotton, some in corn. A good farmer is always supposed to make corn enough to take care of all the stock and his family. Corn is used a great deal as a matter of food. All these little country towns have places where they grind. Of course, where they are able they buy flour to a great extent, and sell their corn; one is about as cheap as the other.

Q. Your customers who are landlords cultivate their land through a system of tenants?—A. Sometimes through croppers and sometimes through what is called day labor.

Q. Will you describe in detail these two plans?—A. The share cropper is one who makes a bargain with a landlord to make the crop on shares. Generally the landlord puts up the land and a mule against the tenant's labor. He furnishes the tenant such supplies as he may want for the family during the year, and charges him an agreed price for everything. Generally that price is a little higher than the man can get for cash in the market. In other words, the landlord becomes a merchant and supplies these tenants in that way. The tenant goes ahead and makes the crop, with his wife and children, and in the fall they gather the crop and divide the proceeds, or sometimes the crop itself.

Q. Are these tenants mostly colored?—A. Nearly all, as a rule; in the northern part of Arkansas quite a good many are white.

Q. What is the other plan?—A. The other plan is where a man owns his own land and raises his own corn and his fodder and hay to feed his stock, and employs men by the day. Sometimes they give them so much to work the crop and what they call "lay it by." That means that the crop is finished and waiting for the warm sun of June, July, and August for the cotton to mature. Then the owner pays a rate for picking—generally from 40 to 50 cents a hundred pounds.

Q. Are these men employed by the month or simply by the day as they actually work?—A. Mostly by the day as they work. They have mule drivers—men to look after and feed the mules—and have them employed by the month.

Q. What is the scale of wages generally paid for that class of labor?—A. In the neighborhood of 60 or 65 to 75 cents a day in some places; in other places not over 50 cents.

Q. Depending on the locality and the supply of labor?—A. Yes, sir; and ability to work.

Q. No food goes with that?—A. The food is not included in this price, but the owner sells it to the laborers—so much meal and so much meat every week. He generally keeps a storeroom, and on Saturdays they come and get meat, meal, tobacco, molasses, and other things necessary.

Q. Do they live on the farm?—A. He furnishes a place to eat, a good house generally, and an acre of ground for a little garden, or a half acre—generally gives them whatever they want, and they generally have wood furnished, but have to go in the woods and cut it.

Q. In addition they are paid these wages?—A. Yes, sir; and as a rule I am quite surprised to see such nice gardens among the working class of people, particularly the negroes. There is a good deal of pride among them as to what they have to eat, and there are a great many vegetables they can raise that go mighty well with bacon and meat. They generally have coffee, turnip greens, spinach, cabbage, and a great many things. They have snap beans; there are a lot of things that they can cook; they cook grits with the bacon.

Q. Is that tenant or laboring class accumulating property? Are they bettering their condition from year to year?—A. As a rule, I can not say they are. There are some very thrifty men. I think on our books we have about 2 negroes who own their own land and are generally very well able to take care of themselves.

Q. They live near by?—A. One lives in Bolivar County, Miss., and the other in Lauderdale County, Tenn., near by.

Q. (By Mr. SMYTH.) Is there a willingness on the part of land owners to sell land to negroes?—A. I think so.

Q. No prejudice against that?—A. None whatever. I might say there is no class feeling; it is very friendly. If called to town on business the landowner feels his family is safe with some reliable negro man in the quarters near the house where the proprietor lives. I think the relationship is just as friendly as that in large manufacturing towns in the North between the rich proprietor and the working people. I speak now of factories in the New England States. If the negro dies on the plantation, he is assured a first-class burial and funeral from some source.

Q. (By Mr. RATCHFORD.) At whose expense, the landlord's?—A. If he is able to pay it, he pays it himself; if not the landlord attends to it.

Q. Has the landlord any way to recover the amount expended in his burial from his family?—A. Not unless the negro who dies had it to his credit.

Q. The family are not taxed thereafter for it?—A. Not at all.

Q. If the negro who dies had it, could not his family bury him without the interference of the landlord?—A. Yes, sir; very frequently I have them on my books and bury them.

Q. (By Senator KYLE.) Do you have much migration here from the Northern States?—A. Well, there has been a great deal of immigration into the Delta country.

Q. Do these Northern farmers operate their places as they do the grain farms of the Northwest and the Mississippi Valley?—A. I think they do at the start, but they gradually work into the ways and customs of the men they employ.

Q. It is quite customary among the farmers in the grain and wheat growing regions for all the family to buckle into the work and hire no help at all.—A. I spoke of the northern part of Arkansas; there is a great deal of white labor there. I know some towns—we have quite a large amount of cotton from Corning, on the Iron Mountain road between here and St. Louis; not many negroes in that vicinity, mostly white people. But that is north, as you know; south, the negro labor predominates.

Q. (By Mr. SMYTH.) Have the Northern immigrants been successful as farmers?—A. I think as a rule. Of course, there are always some men who make a failure at anything, but as a rule those who come down here, live economically and work hard, make a living.

Q. (By Senator KYLE.) Have they not a double opportunity; they both superintend and do the work?—A. None of the farmers in the South are blessed with too much economy.

Q. (By Mr. RATCHFORD.) It is not natural for a man who works hard and is careful and economical to make more than a living?—A. He can do that anywhere unless the wages be starvation wages, as in some of these mining centers where they grind them down to what it takes to live.

Q. What would you consider 50 cents a day, such as is paid now on the farms where men are employed by the week or month, fair wages?—A. I think 50 cents is a little low; I said from 50 to 75 cents.

Q. (By Mr. SMYTH.) I understand with them it includes house and wood, so in making a comparison between these conditions of 50 to 75 cents on the farm, with house and wood and garden patch thrown in, that has to be considered?—A. Yes.

Q. (By Mr. RATCHFORD.) Even though it is considered, do you imagine there is more than a living in it?—A. No, sir.

Q. Do you imagine there is a living in it such as a white man should have?—A. I can not say it is a fine living, but I know many people who do live on it. I tell you the facts as they exist, not what I might hope that they should be.

Q. We are asking you your opinion on matters of this kind, which is valuable to us as well as the facts in your possession. A man can not send his children to school on those wages?—A. Where they have schools.

Q. Does he not need them in the field?—A. Yes; they stay in the field in the summer time.

Q. And are deprived in consequence of an education?—A. Yes; to a great extent.

Q. (By Senator KYLE.) They go to school in the winter?—A. Yes.

Q. (By Mr. SMYTH.) I think the schools run in the winter months only and in

the spring, and the hands work in the field in the summer time.—A. The children in cotton-picking time pick cotton, but as a rule they do not work in the field. A boy 15 years old is big enough to pick cotton and they generally work there and pick cotton in the fall, but the child is not able to make a crop, not able to hoe it, not able to plow; he has not strength enough.

Q. (By Mr. RATCHFORD.) Is it customary to work children 9 or 10 years old in the field?—A. I have never seen any that I know of.

Q. What public-school facilities have they here in the country?—A. I am not so well posted as to the school facilities they have. In nearly all the towns they have public schools for the colored and white people, but I am not posted on the school system and exact conditions in Mississippi, Tennessee, and Arkansas.

Q. You do not know how long the school term is?—A. I do not now recollect. I think it is possibly about 8 months.

Q. You are speaking for the State of Tennessee?—A. That is my general opinion. I am not able to speak intelligently on the subject because I have not looked into it.

Q. (By Mr. SMYTH.) Your business connections are in Mississippi, Arkansas, and Tennessee?—A. Alabama and Missouri also.

Q. (By Senator KYLE.) Do many of these negro laborers leave the farm and come to the city?—A. Yes, sir; a great many of them do.

Q. To better their condition?—A. They do not. They come and loaf about if there is surplus of labor. You will see thousands on the street idle. I do not know where they come from.

Q. I notice many negroes employed on the street. What is the average wage?—A. I think about \$1.50 is paid by the street-car companies for their laborers.

Q. Per day?—A. Yes, sir; and they have had a large amount of work done in the past year—building sewers I think they have been paying about \$1.25. There is quite a large source of employment for negroes on the levee loading and unloading steamers.

Q. These are paid about the same?—A. They get more; generally paid by the hour.

Q. (By Mr. RATCHFORD.) The city's work is \$1.25?—A. I think \$1.25.

Q. What are the hours of labor; do you know?—A. I could not tell you. I do not know whether it is 8 or 10 hours. There has been a great deal of agitation to reduce it from 10 to 8. I think in the last few days the police force service has been reduced from 10 to 8 hours.

Q. (By Senator KYLE.) These men pay house rent. What is the average house rent a man would pay?—A. These negroes live in all kinds of tenement houses. I reckon they pay from \$5 to \$8 a month rent. I can not say that I am posted on that.

Q. Meat and flour and other things cost them more than in the country?—A. No, they cost less if you buy for cash.

Q. (By Mr. RATCHFORD.) Can you say whether the man who is working for the street-car company, say, for \$1.50 a day, is better or worse off than the man who is working on a farm for 50 cents and his furnished house rent and other small things?—A. I take it a man could save more money in Memphis at \$1.50.

Q. You think on the whole he is better off than the man on the farm?—A. I would think so.

Q. His labor is not hard and his hours are shorter?—A. The labor is harder; the work in the country is very easy; plowing is very easy.

Q. (By Senator KYLE.) How about the continuity of the employment?—A. I think they are about the same. In the country if they work for others they cut and haul wood, get out cross-ties, work in timber, and when there is work in the fields there is always some time to do something else. Sometimes they split rails for the employer for so much a thousand, get them out, or do a great diversity of things.

Q. (By Mr. RATCHFORD.) Like men in the city, they can not work in rainy weather, can they?—A. No, sir; at least they do not.

Q. (By Senator KYLE.) Is there anything else you would like to add to your testimony?—A. I think not. I am sorry I was not aware of the character of your interrogatories.

Q. (By Mr. SMYTH.) Do you wish to say anything about the railroad facilities—freight rates? You are a seller of cotton?—A. Yes, sir.

Q. You are not directly interested in the freight rates for shipping cotton to the mills?—A. Yes, sir; I am one of the board of directors of the Memphis Freight Bureau we have organized here. I have spent a great deal of time at that. I think we have very fair freight rates. We have a great many competing lines. We have a number of lines competing to the seaboard.

Q. (By Senator KYLE.) Have you any competition?—A. Not so much this win-

ter because of the contract they have gone into among themselves. I think it has been very rigidly adhered to among themselves.

Q. (By Mr. RATCHFORD.) A pooling system?—A. Yes, sir; the different railroads agree to carry cotton and cotton goods direct to New York, Boston, or any port where the vessel is loaded, and they make a rate there and on down the coast—Norfolk, Charleston, Savannah, Mobile, and all those points.

Q. (By Mr. SMYTH.) Do you know about the difference in rates between points in New England and the Southern mills—say the mills in the Carolinas and Georgia?—A. The subject came up before us at the last meeting, asking that rates be made to the North Carolina mills. Up to this time they claim the rates have been too high to interior points in North Carolina from interior points in Arkansas and Mississippi, and we must try and get rates. That is a matter which I think will adjust itself.

Q. Do you know what the rate to Norfolk from Memphis on cotton is?—A. I could not say.

Q. Is it true that the rate to Charlotte, N. C., is greater than to Norfolk?—A. I think that has been the case. That was the matter that came up before us. If you are on that subject Mr. Davant, who is our commissioner, can give you all that information.

Q. Can he come before the Commission?—A. Yes, sir; he would be very glad. He is a very intelligent gentleman and is commissioner of the freight bureau.

Q. Not employed by the railroads but by the commissioners?—A. He was formerly a railroad man. We have the organization of a freight bureau, and assess each other a good round sum. While it affects my business less than the grocers and dry goods merchants, I felt it my duty to subscribe to it.

Q. Do you believe it to be a fact that the rates to Charleston are higher than to Lowell, Mass?—A. I do not know it to be a fact, but I know it was before us. We had a case the other day where a party wanted to ship cotton from an interior point in Mississippi to an interior point in North Carolina, and he claimed the rate was greater than when passing right through that point to the seaboard point, and Mr. Davant now has the matter on hand. He can give you more reliable information.

(Testimony closed.)

MEMPHIS, TENN., March 23, 1900.

TESTIMONY OF MR. L. C. BALCH,

Lawyer and Planter, Little Rock, Ark.

The subcommission of the United States Industrial Commission met in the parlors of the Peabody Hotel at 9.15 a. m., Senator Kyle presiding. At that time Mr. L. C. Balch was introduced as a witness, and, being first duly sworn, testified as follows:

Q. (By Senator KYLE.) Give your name, post-office address, and occupation.—A. L. C. Balch, Little Rock, Ark.; attorney and farmer.

Q. How long have you lived in Little Rock?—A. For 18 years. I was raised in north Mississippi.

Q. At the present time you are engaged in what particular occupation?—A. In the practice of law and in farming and raising stock principally, horses, cattle, hogs—

Q. (Interrupting.) Real estate business also?—A. In connection with my business as attorney only. I look after the legal part of it.

Q. Have you something to do with the sale of lands in this part of the country, too?—A. Yes.

Q. What can you say as to the increase in value of farm lands in the South in the last few years?—A. In the last six years there has been a very material advance. In 1893, 1894, and 1895 farm lands went very low in this section of the country, and many very large farms could not be rented even, but such is not the case now, and they are bringing fair prices.

Q. To what do you attribute the rise in farm lands?—A. I scarcely know, except the return to prosperous—what might be called properly the normal—conditions of the country. There is nothing specific I could point to.

Q. You take that inasmuch as the public lands of the United States are rapidly being absorbed by the population, the people must fall back on the lands they

the spring, and the hands work in the field in the summer time.—A. The children in cotton-picking time pick cotton, but as a rule they do not work in the field. A boy 15 years old is big enough to pick cotton and they generally work there and pick cotton in the fall, but the child is not able to make a crop, not able to hoe it, not able to plow; he has not strength enough.

Q. (By Mr. RATCHFORD.) Is it customary to work children 9 or 10 years old in the field?—A. I have never seen any that I know of.

Q. What public-school facilities have they here in the country?—A. I am not so well posted as to the school facilities they have. In nearly all the towns they have public schools for the colored and white people, but I am not posted on the school system and exact conditions in Mississippi, Tennessee, and Arkansas.

Q. You do not know how long the school term is?—A. I do not now recollect. I think it is possibly about 8 months.

Q. You are speaking for the State of Tennessee?—A. That is my general opinion. I am not able to speak intelligently on the subject because I have not looked into it.

Q. (By Mr. SMYTH.) Your business connections are in Mississippi, Arkansas, and Tennessee?—A. Alabama and Missouri also.

Q. (By Senator KYLE.) Do many of these negro laborers leave the farm and come to the city?—A. Yes, sir; a great many of them do.

Q. To better their condition?—A. They do not. They come and loaf about if there is surplus of labor. You will see thousands on the street idle. I do not know where they come from.

Q. I notice many negroes employed on the street. What is the average wage?—A. I think about \$1.50 is paid by the street-car companies for their laborers.

Q. Per day?—A. Yes, sir; and they have had a large amount of work done in the past year—building sewers I think they have been paying about \$1.25. There is quite a large source of employment for negroes on the levee loading and unloading steamers.

Q. These are paid about the same?—A. They get more; generally paid by the hour.

Q. (By Mr. RATCHFORD.) The city's work is \$1.25?—A. I think \$1.25.

Q. What are the hours of labor; do you know?—A. I could not tell you. I do not know whether it is 8 or 10 hours. There has been a great deal of agitation to reduce it from 10 to 8. I think in the last few days the police force service has been reduced from 10 to 8 hours.

Q. (By Senator KYLE.) These men pay house rent. What is the average house rent a man would pay?—A. These negroes live in all kinds of tenement houses. I reckon they pay from \$5 to \$8 a month rent. I can not say that I am posted on that.

Q. Meat and flour and other things cost them more than in the country?—A. No, they cost less if you buy for cash.

Q. (By Mr. RATCHFORD.) Can you say whether the man who is working for the street-car company, say, for \$1.50 a day, is better or worse off than the man who is working on a farm for 50 cents and his furnished house rent and other small things?—A. I take it a man could save more money in Memphis at \$1.50.

Q. You think on the whole he is better off than the man on the farm?—A. I would think so.

Q. His labor is not hard and his hours are shorter?—A. The labor is harder; the work in the country is very easy; plowing is very easy.

Q. (By Senator KYLE.) How about the continuity of the employment?—A. I think they are about the same. In the country if they work for others they cut and haul wood, get out cross-ties, work in timber, and when there is work in the fields there is always some time to do something else. Sometimes they split rails for the employer for so much a thousand, get them out, or do a great diversity of things.

Q. (By Mr. RATCHFORD.) Like men in the city, they can not work in rainy weather, can they?—A. No, sir; at least they do not.

Q. (By Senator KYLE.) Is there anything else you would like to add to your testimony?—A. I think not. I am sorry I was not aware of the character of your interrogatories.

Q. (By Mr. SMYTH.) Do you wish to say anything about the railroad facilities—freight rates? You are a seller of cotton?—A. Yes, sir.

Q. You are not directly interested in the freight rates for shipping cotton to the mills?—A. Yes, sir; I am one of the board of directors of the Memphis Freight Bureau we have organized here. I have spent a great deal of time at that. I think we have very fair freight rates. We have a great many competing lines. We have a number of lines competing to the seaboard.

Q. (By Senator KYLE.) Have you any competition?—A. Not so much this win-

investing in establishing mills and giving employment to idle labor between laying-by time and cotton picking time, and between cotton picking time and planting time again. Now, all these plants give employment to the surplus labor during the winter and summer and spring, and that and other causes put the people in better condition. As to the cause of the improved condition of the planters during the last 4 or 5 years, much of it is attributable to the improved method of handling the labor, in this, that the colored people can be induced to buy much less than they formerly did in the way of supplies, which for many years in many cases was much more than the value of the crop they produced. Now, they can be kept from buying so extravagantly.

Q. (By Senator KYLE.) You say you are engaged in raising stock. Can you speak of this industry in your State?—A. Arkansas is—the larger portion of it—adapted to the raising of good stock, but our people have not taken to it much. Fourteen years ago I brought into the State a carload of Holstein cattle and a couple of fine standard-bred stallions, and gave the use of them to the public at a nominal fee, but the cotton farmers are not fixed to raise stock much; the two occupations do not go together very well, and except in the northern part of the State there has not been a great deal of attention paid to stock. They raise a good many mules and draft horses in the northern counties, but there they do not raise cotton.

Q. Does the cotton planter raise his own mules?—A. No, sir. A planter here and there will raise two or three mules a year, keeping the mares for extraordinary occasions in farm work when he needs a little extra team work. In that way they get the mules about clear.

Q. The raising of mules would come in the way of diversified farming?—A. Yes, sir. There is a tendency, last year and this, much more to raising mules in the southern part of the State than ever before.

Q. What is the size of an ordinary plantation?—A. My place is 560 acres, and that is about the smallest one that could be called a plantation in my country.

Q. Of that, what proportion is in cotton?—A. About 40 or 50 acres.

Q. The balance is in grass and timber?—A. A little timber, and the balance in grass.

Q. Abundance of pasture?—A. Yes, sir.

Q. So mules and horses could be raised in conjunction with cotton farming?—A. Yes, sir; they can be raised. I have tried to convince our people that they could raise all the mules they would use clear without a dollar of cost by making the mares earn their living plowing. The ground is light and they do not plow deep for cotton, and the cultivation of it is very light, and the mare will raise her colt and make a fair plow animal.

Q. What can you say as to the condition of the negro, and of him as a laborer?—A. It is the best labor that we have, and I hardly see how we could get along without him under present conditions. He is the most reliable, the most docile, faithful laborer that we have ever had—less trouble. It is true that he don't want to work any more than he has to, and you have to have a few more than if you had white men who were trying to get ahead in the world; but with all that the negro is the laborer for a cotton farm.

Q. How would he compare with a good, energetic, strong young man of 25 years, North?—A. If a young man is brought here from the North, for the first 6 months after he gets here the negro will not compare with him, but after that time the negro has got a heap the best of it. I have tried them. I have hired several Michigan young men, and brought them on my place. For a few months they were throwing things around and swearing they could do twice as much work as any negro, but after the hot weather came on, about cotton picking time, and the thermometer stood 102 in the shade, I have heard them say: "We thought we could do as much again work as the negro, but we find we can not do it." No, sir; the negro is the laborer for the South. He is adapted to the climate—enjoys better health.

Q. What would you say as to negro education?—A. We have the same facilities in our States for the colored as for the whites. The teachers are paid the same—a little different from what they are in Mississippi. It is true they grade them there, but we have a great many colored teachers in our country that have first-grade certificates, and they are paid according to the certificate they get. The negroes have the same facilities, the same schoolhouses, the same time and conditions as the whites.

Q. How do the negroes take to education?—A. They are very anxious to send their children to school, most of them. A few of the old ex-slaves rather disapprove of educating a laboring man, they say. My experience has been that when one of the younger class gets so he can read and write and cipher, he wants to go to

town. It is rare to find one who can read and write and cipher in the field at work. They go to town and take positions to shine shoes, wait on offices—as hostlers, body servants, and house servants. Many do not get employment, and go to the bad.

Q. Don't you think the farm is the best place for the negro?—A. I think there is the place for him to get ahead, decidedly.

Q. He has a better future on the farm than elsewhere?—A. Yes, sir; and the same is true of a majority of white men, in my judgment, if they are of the right sort.

Q. That is my view, too. If the negro is ambitious and wants to get ahead in the world, and is thrifty and economical, of good moral character, honest and industrious, he has a chance to accumulate something in the country.—A. Yes; and a much better chance than the white man, for the reason that society does not call for as much of his time and money in keeping up a position in society as it does on the white man. It would not reflect on the negro at all if he did not have a rag on his floor or have anything but a plain, unpainted bedstead. He would be thought just as much of by his neighbors, and would occupy the same position socially that he would if he had them a great deal finer. Really his opportunities for accumulating money are better than the white man's, because his children and his wife work a good deal in the field.

Q. Have you noticed that they accumulate property of their own?—A. Some do, but it is only a small percentage of them. When you do find one with a disposition to acquire a home, he gets ahead pretty fast and is soon quite independent. We have got a number of them scattered about on the farms in various places that have very handsome properties, own their own homes and stock.

Q. Own the land and free from debt?—A. Own the land and free from debt, lots of them—not a great many, but in every neighborhood there are more or less of them that own farms, some quite big ones.

Q. Have they bought these on the installment plan, so to speak?—A. They have usually bought them on 3 to 5 years' time, paying down about one-third or one-fifth cash.

Q. (By Mr. SMYTH.) Very seldom part with it after they once get it?—A. Very seldom.

Q. They hesitate a long time before they will mortgage that real estate after they pay for it?—A. Yes, sir; after they have got it paid for. Particularly the wife is very much averse to joining in any conveyance in the way of a mortgage or incumbrance. They prize lands very highly when they once own them, and it is a mystery to me why so very few of them attempt to acquire a permanent home.

(Testimony closed.)

MEMPHIS, TENN., March 23, 1900.

TESTIMONY OF MR. ALBERT MASON.

Farmer, Berkeley, Tenn.

The subcommission of the United States Industrial Commission met in the parlors of the Peabody Hotel at 9.15 a. m., Senator Kyle presiding. Mr. Albert Mason was introduced as a witness at 10.46 a. m., and, being first duly sworn, testified as follows:

Q. (By Senator KYLE.) What is your name and address?—A. Albert Mason, Berkeley, Tenn.

Q. What is your business?—A. Farming.

Q. How long have you lived in Tennessee? A. Fifty-six years.

Q. Born here?—A. No, sir; born in middle Tennessee.

Q. Were you a slave in the early days?—A. Yes, sir.

Q. Born a slave and brought up on a plantation?—A. Yes, sir.

Q. You were one of the slaves freed by Lincoln's proclamation in 1863?—A. Yes.

Q. Since that time you have lived in Tennessee?—A. Yes, sir.

Q. Have you been farming ever since that time?—A. Yes, sir.

Q. Most of this time you have been farming as a tenant?—A. No, sir; about half the time—about 18 years. I own a farm now, and before that I was renting.

Q. Tell us how you rented a farm during the early years.—A. When I first rented I rented for cotton rent and paid a bale of cotton weighing 500 pounds for 10 acres of land.

- Q. And in addition to the privileges on the farm you got house rent, use of land, and wood and water?—A. Yes, sir.
- Q. Such things as that?—A. Yes, sir.
- Q. Ordinarily, how are you able to prosper under those conditions?—A. I prospered successfully under those conditions.
- Q. Was your farm on upland or lowland?—A. Both upland and lowland.
- Q. On the delta river bottom?—A. Yes, sir; river bottom.
- Q. How many acres do you take to make a bale of cotton?—A. I have some land where 2 acres will make a bale and some won't. Some will take 4, according to land.
- Q. During this year?—A. For the last 5 to 7 years I have raised cotton very little.
- Q. When you were a tenant—this 18 years—how much would your land produce in cotton?—A. From 25 to 30 bales, the whole farm.
- Q. How many acres?—A. I tended 100 acres in corn and cotton and potatoes, altogether.
- Q. So you pursued a system of mixed farming?—A. Yes, sir.
- Q. You generally aimed to raise enough corn, wheat, oats, and potatoes to feed your family and stock?—A. Yes, sir.
- Q. Did you raise any cattle and horses?—A. Yes, sir.
- Q. Hogs also?—A. Yes, sir.
- Q. So you would be considered a mixed farmer?—A. Yes, sir.
- Q. And you say you prospered and were able to lay by a little sum occasionally?—A. Yes, sir.
- Q. When did you buy a farm on your own account?—A. In 1882.
- Q. How many acres in this farm?—A. In the first farm 80 acres.
- Q. Have you more now?—A. Yes, sir; 198 now.
- Q. Where is this farm located?—A. Shelby County, Sixteenth civil district.
- Q. Upland or lowland?—A. Half upland and half river bottom land—Wolf River bottom.
- Q. Pretty good buildings?—A. Yes, sir. Buildings for tenants.
- Q. You have an orchard?—A. Yes, sir.
- Q. And outbuildings generally?—A. Yes, sir.
- Q. How much did you pay per acre for this land—the first 80 acres?—A. Thirty dollars an acre.
- Q. How much for the subsequent purchase?—A. The second, \$20.
- Q. So that land has cost you \$25 an acre on an average?—A. Yes, sir.
- Q. Have you paid for these farms?—A. Oh, yes, sir.
- Q. Not in debt for the land at all?—A. No, sir.
- Q. Did you buy it on time payments to begin with?—A. Yes, sir; on 3 payments.
- Q. And paid for it in cotton?—A. Yes, sir.
- Q. Have you since been compelled to mortgage it in any way?—A. No, sir.
- Q. You do not feel disposed to mortgage it?—A. No, sir.
- Q. Is that the disposition of your people generally?—A. It is with some. Generally my people go in debt.
- Q. When they once acquire a piece of land they like to keep it clear?—A. Some do; it is not a general thing.
- Q. Generally they do not care much?—A. Yes, sir.
- Q. But with yourself, what induced you to secure a home of your own? What was your ambition to own that land?—A. I saw I had to live and went to work honestly and prepared for living. I thought that would be the best plan—to accumulate a home and go to farming and follow up my business successfully and attend to it.
- Q. Have you sons and daughters?—A. I had 1 daughter, but she has been dead 9 years.
- Q. You have been compelled to hire help?—A. Yes, sir.
- Q. How much cotton per acre on an average will your farm produce?—A. On an average, a quarter of a bale to the acre.
- Q. So it is not above the average as to production of cotton?—A. No, sir.
- Q. So if you were able to buy and pay for a farm under your conditions; any colored man could do so?—A. Yes, sir.
- Q. Provided he goes to work?—A. Yes, sir.
- Q. Have you raised mules?—A. I bought the mules; raised everything else.
- Q. Have you raised any steers or milk cows?—A. Yes, sir. I have not raised many steers; I always sell them off and keep 6 or 7 milk cows continuously.
- Q. How many mules do you operate?—A. Only 4. I had 6 and lost 2 two years ago, and since I have only kept 4 mules of my own.
- Q. You rent, do you not?—A. Yes, sir.

Q. What terms do you give the tenants; the same you got?—A. Yes.

Q. What are the terms?—A. The money rent averages \$2 to \$4 an acre.

Q. Have many of the people of your race been as successful as yourself?—A. Not in my neighborhood.

Q. You say the disposition is not to get down and work with the purpose of owning a home?—A. That is not the disposition.

Q. What is the ambition of the negro?—A. It is so bad I would hate to explain it, so far as I know.

Q. We want to know.—A. I could hardly tell, because it takes me all my time staying at home and attending to my business. I see a very bad spirit in that regard. They get discouraged and say it is too hard, when it just lacks going to work and saving what they get.

Q. No disposition to save money; not economical?—A. Not at all.

Q. They do not like to work continuously?—A. No; not from Monday to Saturday, and save half what they make. They want to go to everything that is on.

Q. What about the education in your community. Have you found the educational facilities good enough to satisfy you?—A. No, sir.

Q. Have you colored schools?—A. Yes, sir.

Q. How long has your school continued during the year?—A. For the last 2 terms from 2 to 5 months.

Q. Ordinarily, a colored child can get a pretty good education during his youth?—A. Yes.

Q. What education do you consider a colored man, or anyone, should have to fit him for the business of agriculture?—A. I consider he should be right well qualified for that.

Q. He should have some knowledge of arithmetic, geography, reading and writing, and ciphering?—A. Yes, sir.

Q. Be able to transact his own business?—A. Yes, sir.

Q. That he can get in the common schools very well?—A. Yes, sir.

Q. Your facilities are fairly good?—A. Yes, sir.

Q. Are your schools taught by colored teachers?—A. Yes, sir.

Q. What disposition do you notice among your people to take advantage of the school facilities?—A. I do not see where they take advantage of them.

Q. When a negro young man gets a pretty fair education, does he show a disposition to want to go to town to live?—A. That is the place for him.

Q. You think that is the place he wants to go, you mean?—A. Yes, sir.

Q. Do you think there is as good an opportunity for a young colored man in the city as in the country?—A. No, sir; I would rather take the country.

Q. Don't you think there is a great future for the young colored man who will take off his coat and go to work in the country?—A. Yes, sir.

Q. Don't you think they may be as successful as yourself if they will go to work?—A. Yes, sir.

Q. (By Mr. SMYTH.) You have made all you have by working and saving?—A. Yes, sir.

Q. Any other colored man could have done the same?—A. Yes, sir; he has the same opportunity.

Q. If he works as hard and saves as much, he has the same opportunities?—A. Yes, sir.

Q. (By Senator KYLE.) You would advise mixed farming for all people who engage in agriculture?—A. When they get to be my age; but when younger and stronger, they should not mix the farm unless they have a knowledge of plants. Of course my age has cut my physical strength down.

Q. You have the experience?—A. Yes, sir.

Q. The young man has not that knowledge?—A. He had better stick to cotton and corn.

Q. Corn is diversified farming—and mules and horses?—A. Yes, sir.

Q. You would advise to diversify rather than put all your eggs in one basket?—A. Yes, sir.

Q. You are able to make your living independently of cotton?—A. Yes, sir; I have done that always. About half my crop, except the first planted after the civil war, I put in corn. My master, who rented to me, always advised me that we could buy our bread and meat cheaper than we could raise it. I said, "Maybe you can; I can't." I farmed and rented of him until I bought the adjoining place with my planting one-half cotton and one-half corn. Finally he commenced drifting down on raising cotton only and buying everything else. As he kept drifting down on that and I was going up, after about 10 years he came and acknowledged, "Your plan is the best."

Q. (By Mr. SMYTH.) He adopted your plan?—A. Yes, sir. I find corn is the strength of the farm. It strengthens the stock; fattens the pigs; the cow gives

more milk; hitch your team in, they can do something. If you have it to buy, it makes them weak.

Q. (By Senator KYLE.) It rests the ground?—A. Yes, sir; and improves the ground. Plant pease and corn and all that, and cows and hogs and such as that could be raised.

Q. What is your age?—A. Sixty-eight.

Q. Have you been in Mississippi?—A. No, sir; only twice in my life. I had 2 mules run away about 12 years ago, and I was down there then, but never lived there.

Q. You think a similar success could be made by diversified agriculture in Mississippi, the same as in Tennessee?—A. Yes, sir.

Q. Where you can raise cotton as you do where you live?—A. Yes, sir.
(Testimony closed.)

MEMPHIS, TENN., March 23, 1900.

TESTIMONY OF MR. PETER EDMONDSON,

Farmer, Memphis, Tenn.

The subcommission of the United States Industrial Commission met at the Peabody Hotel at 9.15 a. m., Senator Kyle presiding. Mr. Peter Edmondson, farmer, was introduced as a witness at 11 a. m., and, being duly sworn, testified as follows:

Q. (By Senator KYLE.) Give your full name to the stenographer, please.—A. Peter Edmondson, No. 311 Main street, Memphis.

Q. And your occupation?—A. I am a farmer.

Q. What is your age?—A. My age is 46 years.

Q. Were you born a free man?—A. No, sir.

Q. Born in slavery, were you?—A. Yes.

Q. And was freed at the time the negroes were freed during the sixties?—A. Yes.

Q. Since that time what has been your occupation?—A. Well, part of my time I have worked for wages, until I became a married man, and after that I went to farming with my father and stayed with him until his death.

Q. Where did you work for wages?—A. Out in the seventh district.

Q. By the month, you mean?—A. Yes.

Q. What did you get per month?—A. I got \$15 per month. I was the regular wagoner on the farm.

Q. Were you able to save some money during those days?—A. I did not save much during those days.

Q. How old were you when you were married?—A. Twenty-one years of age.

Q. Did you then rent a farm?—A. No, sir; I remained with my father. I stayed with him until his death, and after his death I took charge.

Q. During this time you were engaged in cotton raising?—A. Yes.

Q. So you understood that business?—A. Yes.

Q. When did you begin renting on your own account?—A. It was in 1884 I began renting on my account.

Q. Where was that?—A. That was over on the Tennessee Midland road, in the ninth district.

Q. Were you able to make good cotton there?—A. Yes.

Q. How much to the acre?—A. I was upon pretty good land there, and I was working for J. C. Rogers. He was a stockman and he would rent it to me, when I would reverse it as the clover died out on it. I made about a bale—nearly a bale—to the acre on clover land—thin land. I made 21 bales of cotton on about 26 acres.

Q. What was cotton worth during 1886?—A. It was staple quality, what we called Allen cotton; it was worth all the way from 10 to 13 cents, according to the grade or staple. The Allen staple was not so large, but was as long.

Q. (By Mr. SMYTH.) This cotton was long staple?—A. Yes.

Q. (By Senator KYLE.) Were you working on shares?—A. Yes; I was giving him a third.

Q. Giving a third and you did all the work?—A. Yes.

Q. Furnished your own team?—A. Yes.

Q. (By Mr. RATCHFORD.) And he furnished nothing but land?—A. Yes.

Q. (By Senator KYLE.) You furnished rations and wood?—A. Yes.

Q. And such things ordinarily furnished?—A. Yes.

Q. Well, were you able to get out even under these circumstances?—A. Yes; that year I got out; then I made on rice \$600.

Q. (By Mr. RATCHFORD.) You were more than even then?—A. Yes.

Q. (By Senator KYLE.) Well, did you have a disposition to save that money then?—A. Yes; I saved up until I bought a good wagon and pair of mules, and when they put up the Tennessee road over there I had the misfortune to lose both. I gave \$125 for a large mare mule I got.

Q. You rented under these conditions for a number of years, did you?—A. Yes; not at that place; he never allowed to but one year, then reversed it.

Q. You have been renting off and on from that time to this, have you?—A. I quit renting. Then I came down here to G. R. Conner, and went to working on shares with him to get a stake again.

Q. You are beginning over, so to speak, now?—A. Yes.

Q. So you think by the same kind of economy practiced in the past that you can get ahead?—A. Yes; that is what I am trying to do. I worked 3 years, and I made 20 bales of cotton a year.

Q. (By Mr. RATCHFORD.) What part of that was your own?—A. Half of that was my own.

Q. (By Senator KYLE.) So you had 10 bales to sell this last year?—A. Yes.

Q. That would amount to how much a bale?—A. All the way from \$36 to \$38.

Q. Nearly \$400?—A. Yes.

Q. During this time were you able to raise some garden truck and keep a pig or two?—A. Yes, sir. I bought two male pigs for \$5, and I just weighed them, and they weigh 213 pounds one and 210 the other.

Q. So you were able to save part of this sum of money each year?—A. Yes.

Q. Well, with ordinary good luck, so to speak, in the course of 3 or 4 years you will be able to buy a piece of land?—A. Yes.

Q. That is your ambition?—A. That is my ambition; yes. I have got a good family, and I work them hard.

Q. (By Mr. RATCHFORD.) How large is your family?—A. I have 8 boys.

Q. All working?—A. I have 3 of age; the balance of them are working.

Q. Your wife work in the field?—A. Yes.

Q. Got any daughters?—A. They are not with me.

Q. Did you work them in the field when you had them?—A. Yes; I worked them in the field to the full extent.

Q. (By Senator KYLE.) That is good education for them?—A. Yes. You will never find any in the workhouse or penitentiary when you work them in the field.

Q. You also sent them to school?—A. Yes.

Q. What about the school facilities?—A. Well, they are pretty good, you might say. I sent them over to Mount Zion, over there; they have a good teacher over there.

Q. Average about 3 months in the year, do they?—A. Yes; the time is pretty well out now, and they must come in.

Q. You think the ambition you possess in regard to yourself and family is a characteristic of your race?—A. Yes.

Q. You think they generally work to get ahead?—A. Well, the majority do, and then there is a part that do not, that just want to come out even, and then start again, but that is not my ambition. I do not like that.

Q. Do you think that the opportunities for a colored man are better in the country than in the town?—A. I would take my own in the country before I would in town; yes. I believe a man can make a better living in the country. If he is a man of my standing, wants to farm and wants to work for a living, I believe the country is his place.

Q. Sometimes in town there is a little more cash return?—A. Yes.

Q. More amusements, etc., for the time being, but in the end they do not save as much?—A. No, sir. The dollar comes this week and goes Saturday night.

Q. (By Mr. RATCHFORD.) What part of your success do you owe to your large family? How much—in other words, would you have been able to accumulate as much as you have accumulated if you had but yourself and wife and a couple of children to support?—A. No, sir.

Q. Has every colored farmer the same number of children—the same opportunities—that you have?—A. They have the same opportunities that I have—the wife and himself, yes, but do not have the children.

Q. The children are a material help to the family?—A. Yes.

Q. That is to say, they are worth more than it costs to support them and clothe them?—A. Yes.

Q. (By Mr. SMYTH.) It is a good investment to have a large family?—A. If a man has children he has peace at home and peace in the field.

Q. Peace with mankind?—A. Yes.

(Testimony closed).

MEMPHIS, TENN., *March 23, 1900.***TESTIMONY OF MR. JEROME HILL,***Cotton Dealer, Memphis, Tenn.*

The subcommission of the United States Industrial Commission met at the Peabody Hotel at 9.15 a. m., Senator Kyle presiding. Mr. Jerome Hill, cotton dealer, Memphis, Tenn., was introduced as a witness at 11.11 a. m., and, being duly sworn, testified as follows:

Q. (By Senator KYLE.) You may state your full name and address.—A. Jerome Hill; Union avenue, Memphis, Tenn. I am located at No. 334 Front street.

Q. Your business?—A. I am a cotton dealer.

Q. (By Mr. SMYTH.) You advance to the planters in the country around?—A. No, not now.

Q. You receive consignments of cotton for sale?—A. No.

Q. You discontinued that business?—A. Yes. I buy cotton and operate ginneries.

Q. What is the general opinion of the condition of the farmers here and planters?—A. I think it has improved in the last few years somewhat.

Q. Did it improve during the condition of 5-cent cotton—during that period?—A. No, sir.

Q. You do not believe that cotton can be raised at 5 cents?—A. I know it can not and pay a profit to farmers.

Q. What do you think it costs to raise cotton in this country?—A. I think the actual cost is about 5 cents, and in the hill country about 6, without any compensation for wear and tear of stock or utensils—I mean farming implements—or interest on investment. I think that would be the cost.

Q. Do they use fertilizers in the hill country?—A. Not in this section.

Q. (By Mr. RATCHFORD.) What would be the cost, including the cost of wear and tear of farming utensils?—A. It depends a great deal, I suppose, on what would be the care taken of them and purchasing the same.

Q. With ordinary care and ordinary use would it increase the cost 1 cent a pound or half a cent a pound, do you think?—A. The profit, you mean?

Q. The cost of producing it.—A. A half cent more. It is well enough to explain that. Two years ago it cost less to make cotton than this year, for all the outlay on a plantation that you have to make now has enhanced a great deal. For instance, I am paying about \$4 for barbed wire that I got for \$1.75 two years ago. That applies to iron and everything in the industrial line.

Q. And cotton is higher?—A. Yes; cotton is higher.

Q. (By Mr. SMYTH.) Well, on the whole, you think the condition of the planters and farmers in this territory is better than it was a few years ago?—A. I think it is; I think it is improving some.

Q. Can you say it is better than at any time since the war?—A. No; a little after the war I think it was a little better. Labor was more regular and more to be relied on.

Q. And the price of cotton was higher immediately after the war?—A. Yes; for probably 5, 6, or 10 years.

Q. Is land owned around here in large tracts?—A. Not so much so as it used to be. It is being cut up into smaller farms.

Q. What percentage, Mr. Hill, of the farmers around here own their own land?—A. I never thought of that very closely. I can not answer that; or I should say—if you mean the white farmer or colored—

Q. The white.—A. Oh, I should say 80 per cent of them own their farms, or 90 per cent.

Q. Now, can you give us an idea of the number of farms under mortgage?—A. No. I want to say the mortgages have been greatly reduced in the last 12 months, owing to the advance in cotton.

Q. Can you tell us something about the colored labor in this section? Is it as satisfactory as it has been?—A. I do not believe it is.

Q. Are they leaving the farms?—A. Yes; too much so.

Q. Coming to the towns and cities?—A. The last reports show it. Anticipating that question, I sent over here to the schools a while ago to find out from Mr. Gordon, superintendent of public schools here, how it was in Memphis. I am sorry to say that there seems to be a disposition to go to the towns amongst colored people, to go off the plantations. I know that to be the case on my own plantation.

Q. What is the custom of hiring labor on the farms here? Is it on the share system or the tenant system?—A. The plantations are run differently; some rent; most of them are run on the tenant system, but some people run them and pay cash for the labor.

Q. Which is the most satisfactory to the landlord?—A. Well, I can not tell you. I think running it, paying cash for labor, the most satisfactory; I have tried them both.

Q. Does the land that is rented out to the tenant receive the same attention as it would under the care of the landlord?—A. No, sir. That is the objection to the tenant system; that is the most serious objection.

Q. The tenant generally objects to taking any advice in regard to the cultivation of crops?—A. Well, he may take advice very well, but he would not attend to the protection of the property as you would if you took care of it yourself.

Q. Is there a disposition on the part of the colored people to buy farms?—A. I do not think the tendency on the part of the colored people to buy farms has very much increased. From my experience I can not tell you.

Q. Do they find it difficult to buy land?—A. No; they can buy land.

Q. And land will be sold as readily as to the whites?—A. Yes. Speaking about this going to town, I want to show you this. The scholastic population of Memphis between the ages of 6 and 21 is 12,353 whites and 13,564 colored.

Q. More colored children in the schools than whites?—A. The scholastic population shows 1,200 more colored children than white children. I do not know whether or not there are that many more in the schools.

Q. That is the school district of Memphis?—A. The city of Memphis. I got this anticipating that question. I wanted to know myself, and I sent over to Mr. Gordon's office, and there is the paper he sent me.

Q. Those schools are supported by the taxes of the people of Memphis?—A. Yes.

Q. What proportion of the taxes are paid by the colored people?—A. Very little; I can not tell you.

Q. Is it 10 per cent?—A. I do not believe it is. Ninety per cent of the taxes in support of the schools are paid by the white people of Memphis, and the colored people are enjoying the privileges of the whites.

Q. So every opportunity is given by the white people of Memphis to educate the colored people at the expense of the white people?—A. Yes, and I think at the expense of the propriety of the colored people; I really think their coming to town is a great injury to them. I think if they will stay out and be farmers—they have district schools in Mississippi, Arkansas, and Tennessee, and they could attend these schools just as well, but they have a great big hobby to come to town to be educated.

Q. That, they think, brings them to social equality?—A. No; I think they become discontented.

Q. Their object in getting an education, you think, is to bring them on an equality with the whites?—A. Well, I do not know what the colored man thinks. Probably he may think it will do it.

Q. You heard the testimony of Mr. Mason?—A. I did not hear the first part, what he said about that. I was very much interested in the last part of it.

Q. You consider him one of the old-school negroes?—A. Yes.

Q. They also learned the best industry during slave days?—A. Yes; it is very marked. On my own plantation, 5 miles in the country, there are a few of the old ones. They are very well satisfied, happy and contented about things, and the younger ones are very discontented and want to be roaming.

Q. (By Senator KYLE.) The old ones have industrial habits already formed?—A. Yes. The others are inclined to be idle.

Q. That was his own testimony?—A. They are inclined to stick their hands in their pockets after making \$2; go to town and spend it. They go out and work a few days and then return to the village and lead a happy, go-easy life until their money is gone.

Q. (By Mr. SMYTH.) The colored man doesn't control the children as well as the old slave parents did?—A. No; they don't.

Q. (By Senator KYLE.) During the days of slavery the children were somewhat under the guidance of masters?—A. Yes.

Q. As regards forming industrious habits?—A. Yes; and moral habits, too.

Q. And since that time they seem to love to drift?—A. Yes. Some darkies work very well indeed, and some of the labor amounts to nothing at all; they won't work.

Q. (By Mr. RATCHFORD.) I did not catch the answer in regard to the method of running a plantation at the present time.—A. I have abandoned raising cotton very largely. I have what I call wage hands. I raise wheat, grain, cattle, and hogs with wage hands.

Q. And pay the hands by the week or month?—A. Pay by the month, or by the week; I hire by the month.

Q. What wages do you pay every month?

The WITNESS. For the men?

Q. Yes.—A. Ten dollars.

Q. And found?—A. Yes.

Q. How many men do you employ as farmers?—A. Six to ten.

Q. (By Mr. SMYTH.) You furnish them houses?—A. Yes.

Q. Wood?—A. Yes, board and everything; have their meals cooked for them.

Q. Furnish firewood?—A. Yes; I furnish everything—houses, everything else.

Q. (By Mr. RATCHFORD.) Do you find that more advantageous than farming on shares?—A. Well, yes. The farm is one of the older ones, which has deteriorated for want of attention, but I am endeavoring to reclaim it. It is 50 miles north of here, near Bolivar, Tenn. It was very fertile during the time of our forefathers and quickly responded to the agriculturalists of the early times. It was a very prosperous country early in the century. Your Mr. Kyle speaks of this country as being broken and thin, but it was a fine country in the early days. Some of the tenants on this place have been there over half a century. The place was one of the first settled in Hardaman County, and there have been three generations of colored people there.

Q. How large is that plantation?—A. Three thousand acres. My wife inherited it. There is one old darky there now who has been there 68 years; was born there; she is around the house now feeding the chickens.

Q. Do you regard the condition of the colored man as improved to-day over that of slavery?—A. I am going to answer that in two ways. I am glad he is free. I do not believe he is improving now.

Q. Do the white people pay the same attention to the family training of the colored people as they did in those days?—A. No, sir; that is the trouble about it. The colored people won't live in the yards with the white people; they want to get out by themselves. It is hard to keep your servants and help on the place.

Q. (By Senator KYLE.) Perhaps he feels absolved from responsibility around?—A. Yes.

Q. (By Mr. RATCHFORD.) The claim that is sometimes made as regards their moral training during times of slavery is correct, is it, that the owner of the slaves, and often his wife and family, looked to them in that respect and exercised considerable care and caution that their morals were preserved?—A. I know that to have been the case.

Q. That is true, is it?—A. Yes; I was raised on a plantation.

Q. Let me ask you another question. Is the cost of colored labor higher to-day on the farms than the cost of maintaining the colored labor during slave times? Do they live better to-day?—A. The colored man doesn't live as well.

Q. The cost, then, is necessarily lower than it was in those days?—A. Yes; take it on the average. I have not been there in a good many years. I was very much astonished to see how things go down. It was their own business; they had absolute control and let things go to waste. Their rations are so much confined to bacon and corn meal. You know—when they were in slave times—they had a cow and they had milk, and they would get different kinds of vegetables and everything to eat, and for a few years after the war they lived very well; but they let down in that; they don't keep up the garden, do not keep up the house, and they have no pride.

Q. To make your answer perfectly clear I will ask the question in another way: Did it cost the slave owner more under slavery to support the darky than he pays him under wages for his labor?—A. I understand what you mean. It cost him more.

Q. During slave time?—A. Yes, in my opinion.

(Testimony closed.)

MEMPHIS, TENN., March 23, 1900.

TESTIMONY OF MR. J. A. MANSON,

Farmer, Saulsbury, Tenn.

The subcommission of the United States Industrial Commission met at the Peabody Hotel at 9.15 a. m., Senator Kyle presiding. Mr. J. A. Manson, farmer, of Saulsbury, Tenn., was introduced as a witness at 11.30 a. m., and, being duly sworn, testified as follows:

Q. (By Senator KYLE.) What is your address, Mr. Manson?—A. Saulsbury, Tenn.

Q. What section of the State is this?—A. It is 57 miles east of this, on the Southern road.

Q. What is your vocation?—A. Farmer.

Q. Were you born in the locality where you now reside?—A. No, sir. I was born in Georgia, about 35 miles from Atlanta.

Q. You were a farmer there, were you not?—A. Well, I was not old enough to farm. I was on the farm there; my father farmed very extensively.

Q. So farming has been your life avocation?—A. Yes. Well, I do not know. I have been in politics a good deal, and have been United States marshal.

Q. You have produced cotton and cereals, I presume, for many years?—A. Yes; for several years now. I taught school a good while, for a while; for several years now I have been producing cotton.

Q. The section where you now reside is especially well adapted to cotton, is it?—A. Well, as well as any section in this country. The lands are not as rich as the bottom lands down here.

Q. You own your own farm?—A. Yes.

Q. And how large a plantation is it?—A. Well, I own 3; I own about 2,500 acres in all.

Q. How much cotton does your land produce, on an average?—A. I think about a bale to 3½ acres.

Q. So you would not call yours one of the best cotton-producing farms?—A. No, sir. Well, say 3 acres—I think a bale to 3 acres. The average in our county, up there, I expect, is about a bale to 4 acres.

Q. Do you produce cotton yourself by hired help, or let out land to tenants?—A. I produce it in three ways. I generally keep about a half a dozen hands. Then I rent two places to negroes; then I have got some working on shares—halves we call it.

Q. What is this share plan?—A. I furnish everything—the mules, feed of the mules, and everything, and get half the profit.

Q. You furnish mules, too?—A. Yes.

Q. Furnish everything?—A. Furnish all plow tools, wagons—everything of that sort.

Q. What wages do you pay the hired help?—A. I pay about \$8 a month.

Q. Men, are they?—A. Yes.

Q. And these men you employ raise cotton, or what?—A. Well, I employ on a place of that size, on my upper farm of about 2,000 acres—a good deal of that I do not cultivate. I allow cattle up there which I keep as range cattle.

Q. (By Mr. SMYTH.) What do they get besides \$8 a month from you? Do you feed them?—A. Yes.

Q. Furnish house-room and wood?—A. Furnish house-room, firewood, everything.

Q. (By Senator KYLE.) Cook for them?—A. Yes.

Q. Well, you find that you can raise cotton at the present prices by this hired help, do you?—A. I do not think I could if I did not need the help for something else, you know. These tenants and other croppers do not want to work to keep the place up, keep the fences up, and everything of that sort.

Q. And fertilizing and so on?—A. Yes. Well, we have never used any fertilizer up there. I am going to use 6 tons this year, and try it.

Q. Except barnyard fertilizer?—A. No; I bought 6 tons of commercial fertilizer this year.

Q. You raise wheat and corn?—A. No, sir. I raise corn, and I planted a considerable acreage of wheat year before last, but the winter of 1898-99 was terribly cold and killed it. Nearly all had a wheat crop last year, but it did not amount to much.

Q. How about cattle, horses, and mules? Do you raise many of them?—A. I have not raised any mules; only I have 1 or 2 young mules there.

Q. You use these animals, do you not, in raising cotton?—A. Yes.

Q. You buy them?—A. Yes. I have 2 mule colts there.

Q. Well, what I want to get at is this: Do you think it is more economical to buy them than to produce them?—A. No, sir; I do not. I have owned that big farm out there but a few years—4 or 5 years—and I know it is more economical to raise them.

Q. And to make a success of agriculture you think diversified farming is the best plan?—A. Yes. I have my sheep and cattle—90 head of cattle—and to those tenants of mine I furnish milch cows and charge nothing for it.

Q. Cattle are profitable, are they not?—A. Yes.

Q. Sheep also?—A. Yes; sheep also.

Q. And you could raise the mules you need for cotton farming?—A. And ought to do it.

Q. And raise all your own meat on the farm, I presume?—A. Yes. I don't reckon my meat cost me 2 cents last year.

Q. (By Mr. SMYTH.) Two cents a pound?—A. Yes. Then I have a range out there. I turned about 25 hogs out last fall when the acorns began to fall and I did not see them from the 1st of October until about the middle of January; they were 3 or 4 miles up on the hills.

Q. (By Senator KYLE.) All fat when you saw them?—A. Yes.

Q. Well, would you call your farming generally successful?—A. Yes. I have not really made any money on the farm since I bought it. It had gone down considerably, being rented year after year. For 4 or 5 years I improved the house and everything on it, and I do not reckon I have gotten any more money than I have paid out on it so far.

Q. But you have made money, barring improvements?—A. Oh, yes; I think so; some.

Q. And the money taken in on the farm you invested in improvements?—A. I have made some this year. I have not sold the cotton yet; I am waiting for 10 cents.

Q. (By Mr. SMYTH.) The place would sell for more than you paid for it on account of the improvements?—A. Yes.

Q. (By Senator KYLE.) Do you find agricultural lands advancing somewhat in price?—A. Well, not much. They would if the price of cotton kept up this way a year or two; but when cotton is down to 5 cents—a great many farmers did not get as much as 5 cents a pound for any cotton sold year before last.

Q. You can not raise cotton at 5 cents?—A. No, sir.

Q. What do you think is the minimum cost of production?—A. If a man hires hands and pays \$8 a month he can not raise it for less than 7 cents on lands that produce what ours do—about 3 acres to the bale.

Q. So, during these years when cotton was 4 and 5 cents, and 5 and 6 cents, the farmer was not really getting out even in cotton?—A. No, sir; and the tenants had to live very hard. Wages had to be held back, and they could not let them go. A family might be more than \$60 in debt and probably would not pay out. Now, a man can not raise cotton at 5 cents in our section. He may do it down in the Mississippi bottom where there is a larger number of bales to the acre, but I doubt that.

Q. How about the school facilities in your region for both white and colored?—A. Well, just the same, sir; but the negro does not take much interest in school. As a general thing, we have about 4 months a year, 3 months in winter and 2 in summer.

Q. Colored teachers?—A. Yes. They do not want anybody else, and we let them have their own way about it.

Q. The white people pay the tax?—A. Yes.

Q. You think there is a disposition among the colored people to accumulate property—mules, horses, wagons, and land?—A. Not much. There are a few up there, good old negroes, as we call them, that have farms; negroes about grown before the war.

Q. Naturally industrious?—A. Yes; but the negroes get worse all the time, and the whole business is more and more immoral every year. It is my opinion there is not one negro girl in our county 18 years old that is virtuous, and the negro men just the same. The married ones are just the same as the others, and the preachers are just as bad as the others. I stayed out on my farm all last year, and my family lived in town, and I talked with the older ones about it, tried to get them to do better. The majority of the church people are on the other side, but I am very sorry to see it; it is just that way.

Q. (By Mr. RATCHFORD.) That is a startling statement, is it not, regarding the virtue of the colored people?—A. It is, yes.

Q. Do you think farm life is conducive to these results?—A. Well, I do not think that.

Q. Are they more moral in the city?—A. I do not know much about them in the cities, but it just seems to be in them—the married men and preachers. There is a preacher there within a mile of me, and he had a sister come there and live with him. Well, she had a baby; then they had him up in church and he was turned out, but is back again.

Q. Are those people who practice this immorality educated to any extent? Have they a common-school education?—A. This man can read and write.

Q. I speak of them generally?—A. Well, a good many of them—no, sir. A boy

gets to be 14 or 15 years old, and he don't want to go to school, and the parents don't make them. They would rather run away and do nothing in the summer.

Q. Do you think that better school facilities and consequently, a better education would tend to improve the morals of those people?—A. I am afraid not, sir; I am afraid not. For 30 years we have given them just the same advantages in the public schools as the whites have had, given a pro rata of all the taxes paid.

Q. (By Senator KYLE.) You think if a man is bad, the more education he has the worse he is off?—A. That is it, and when you get one that can read and write and cipher a little he don't want to work on a farm any more.

Q. (By Mr. RATCHFORD.) Well, I can understand how a limited education will not improve morals, so long as the surroundings remain what they are, but with that higher education, would the tendency not be toward a higher standard, and consequently more decency, better morals?—A. Well, I hope so, sir; but I have almost lost confidence in regard to their morals. There is a preacher out here in this country who said this: "I know you girls are nearly all going wrong, but I want you to confine yourself to the members of this church." A great many of them have syphilis. There is a negro on my place of about 21 years now. I had a man on my place last year that I thought was an excellent man. I was a little surprised at him. Along before Christmas he was picking cotton and he said it was no harm for a married man to monkey with other women if no harm came of it. I found out he had been at it. I thought if there was a straight negro in the whole country that was one.

Q. (By Mr. SMYTH.) Do many negroes that have a little education commit forgery? Do you have trouble of that kind?—A. When I was United States marshal we had a good deal of it in the pension business.

Q. A little knowledge enabled them to commit forgery?—A. Yes, sir.

Q. Are there many in the State penitentiary for forgery?—A. Yes, sir. I do not know about that. I notice that 75 or 80 per cent of the negroes in the Georgia penitentiary can read and write, and that is a very large proportion—much larger proportion than there is among the negroes out of the penitentiary.

Q. That has been cited as a frequent crime among educated negroes.—A. We had a great many when I was United States marshal.

Q. (By Mr. RATCHFORD.) What percentage of the colored people in the penitentiary compared to the total number of convicts?—A. I suppose 75 per cent or maybe 80 per cent.

Q. What is the percentage in the State of the white to the colored?—A. Maybe 33½ per cent colored in the State.

Q. (By Mr. SMYTH.) Two-thirds white?—A. Yes, sir.

Q. (By Mr. RATCHFORD.) Two to one?—A. Yes, sir.

Q. (By Mr. SMYTH.) In the penitentiary they are 3 to 1 colored?—A. Yes, sir. If we were to take up every negro guilty of bigamy there would be 100 in our county. They get tired of one woman and go and marry another, and you can not prove anything.

Q. So it is quietly overlooked?—A. Yes, sir. I am very sorry to see it. Several years ago an old before-the-war negro talked to me. He had several grown daughters, and he talked to me about it, and he said, "They are all gone wrong," and tears ran down his face; he said it was not that way before the war. Soon after the old negro went crazy and died, and I think that is what killed him, the way his family went wrong. Their morals are 10 times worse than before the war. Negro women themselves—if a negro had a bastard child they had nothing to do with him before the war; now it makes no difference. A negro man would just as soon marry a woman with 3 or 4 bastard children as anybody else. It makes no difference now.

Q. (By Senator KYLE.) Does this condition prevail generally throughout the South?—A. I am afraid it does.

Q. In Georgia?—A. I have not lived in Georgia since the war.

Q. You have had quite a wide experience, being United States marshal and traveling over the country, so you are generally conversant with the situation?—A. Yes, sir; and I have had some negroes to bring down from Jackson to work their terms in Georgia, that had syphilis so bad you could not stay in the same house with them.

Q. Jackson, Tenn.?—A. Jackson, Tenn. There are 2 Federal courts in this division, 1 at Jackson and 1 here.

Q. (By Mr. RATCHFORD.) Is it your opinion that the present state of the colored man in the South—his presence here—operates against the investment of Northern capital in your country and the immigration of Northern people?—A. I think so.

Q. Does it operate to a large extent in your opinion?—A. I think it does. The Northern man comes down and settles among us, and he has not as much use for the negroes as we have; is not as patient with them.

Q. (By Mr. SMYTH.) He does not understand their characteristics?—A. He thinks every man ought to obey the law. I think we made a mistake in this country soon after the war in overlooking these things. We ought to have brought them right down to the law, but it was not done. The negro steals a hog and he gets off a heap lighter than the white man.

Q. (By Mr. RATCHFORD.) Do you agree with the previous witness that negro labor was more costly to the planters of the South before emancipation than it is at the present time?—A. Not altogether, when you take into consideration the much better control we had them under before the war. I do not think it was more costly; you could control them.

Q. You think that was worth something?—A. A great deal.

Q. Speaking of labor alone, was their labor cheaper or dearer in those days than it is to-day?—A. I think it was dearer in those days. The negroes were taken a great deal better care of. If a negro got sick, dangerously sick, they took him right in the house and looked after him. Then, on my father's farm every grown negro man with a family had a cotton patch of his own to buy his Sunday clothes with and little extra things. They had plenty to eat and wear and they dressed better than they do now on Sunday. Of course some have prospered and educated themselves, but taking the whole race, I am satisfied they were better off before the war.

Q. Do you believe that it is a mistake for the negro to branch out in the professions rather than confine himself to agriculture?—A. No, sir; not if he is capable.

Q. You think these avenues ought to be opened to him and that he should avail himself of them?—A. Yes, sir; and we have some pretty good negro lawyers here.

Q. It is claimed by some that the farm is the natural vocation of the negro.—A. It is for nineteen out of twenty of them.

Q. (By Senator KYLE.) Have you facilities for the higher education of the negro in Tennessee?—A. Yes, sir; the Fisk University at Nashville.

Q. Supported by the State in whole or in part?—A. In part only.

Q. Have you observed these graduates as they have gone back into private life, as to their habits, their success?—A. I have never seen a great many of them. I was in the legislature several times with negroes who behaved themselves well.

Q. You think these educated negroes who come from the higher schools are elevated in their morals as well as in their educational qualifications?—A. I am not certain about that.

Q. (By Mr. SMYTH.) Do you find that education among the negroes on the farm tends to elevate them in a moral sense?—A. No; and it never will until the preachers do better; they are as bad as any. You can not expect children to be more moral than their parents. The mothers in any nation shape the morals of the children.

(Testimony closed.)

MEMPHIS, TENN., March 23, 1900.

TESTIMONY OF MR. T. F. HUTCHINSON,

Representative of American Cotton Company.

The subcommission of the United States Industrial Commission met at the Peabody Hotel at 9.15 a. m., Senator Kyle presiding. Mr. T. F. Hutchinson was introduced as a witness at 11.57 a. m., and, being first duly sworn, testified as follows:

Q. (By Senator KYLE.) Will you please state your name and post-office address?—A. T. F. Hutchinson, 61 Porter Building, Memphis, Tenn.

Q. What is your vocation?—A. I represent the American Cotton Company, round lap bale system.

Q. (By Mr. SMYTH.) What advantage do you claim for the round bale?—A. From what standpoint? The farmers' standpoint?

Q. Yes, sir.—A. He gets more money from it; for a given grade of cotton in the round bale he gets more money than for the same grade in the square bale.

Q. Is that the fact in Memphis?—A. That is the fact in Memphis territory.

Q. Are any round bales received here at Memphis?—A. Yes, sir; some were received here during past seasons, shipped in here to factors by parties who were mortgaged to the factors; but nearly all the round lap bales are sold direct, and do not have to go to Memphis.

Q. Was that which was sold here sold at a higher price than the square bale?—
A. Yes.

Q. Is there any objection on the part of foreign spinners to the round bale?—
A. None that I know of.

Q. Is it a fact that any of the brokers here or elsewhere have instructions to avoid the round bale and not ship it?—A. Not that I know of. I have had applications from a good many brokers here to buy round lap bales.

Q. Is there any difficulty in sampling or boring into the round bale?—A. No difficulty in sampling, taking out a sample as in other bales.

Q. That is only from the outer bale. Is there any way of sampling into the core?—A. No.

Q. So bales that are false packed could not be detected before shipment?—A. It is not necessary to bore them. The American Cotton Company guarantee the bale to the spinner.

Q. How can they do that if they sell their presses?—A. They have not sold any presses.

Q. They simply lease these presses to ginner?—A. Yes.

Q. On a royalty of how much?—A. Twenty cents a hundred.

Q. Equivalent to \$1 a bale?—A. Yes; if the bale weighs 500 pounds.

Q. The planter has to pay \$1 extra to have his bale put up under the round bale system?—A. Yes; and that is paid back in the premium over the old system.

Q. What is the premium?—A. Forty-five points.

Q. Is that universally allowed?—A. Yes, sir.

Q. Do you believe any round bale cotton has been sold at the same price as square bale cotton?—A. I have heard of none.

Q. How many bales in the Memphis district were put up in the round lap bale last year?—A. I could not quote the figures definitely, but about 75,000.

Q. Why will not your company sell their presses to the farmer?—A. The farmer would not buy them.

Q. Well, to the ginner?—A. He would not buy them.

Q. Why not?—A. Because they are afraid of the compress interest.

Q. Have they been offered to them?—A. Yes, sir.

Q. They refuse to buy them?—A. Yes, sir.

Q. What would be the selling price?—A. I am not able to answer that question. I have nothing to do with the manufacturing department and do not know the cost of the press.

Q. You do not know the price at which it was offered to the people?—A. No, sir.

Q. Perhaps the price was prohibitory?—A. You may take any lessee that we have had for the past 2 or 3 years, and make him a proposition to sell the press at \$500 and take away the protection of the American Cotton Company, and he would tell you that he did not want it at any price.

Q. What is the protection?—A. An agreement guaranteeing this premium.

Q. On every bale sold?—A. Yes; and the American Cotton Company stands ready to buy it any day, if offered, with that premium added. This cotton agreement, however, does not bind the ginner or farmer to sell a single bale to the American Cotton Company. He may sell where he pleases. It is simply a guaranteed market for his round bale with the premium.

Q. If he will pay the dollar extra?—A. Yes, we guarantee the \$2.25.

Q. Does not the farmer, under the round bale system, use much less bagging and ties than on the square bales?—A. He uses no ties at all.

Q. And he uses very light bagging, much lighter?—A. Lighter, yes.

Q. Does not the farmer now on the square bale make a handsome profit on the bagging and ties on the bale?—A. I do not know. He makes something on the bagging and ties. The price of bagging and ties has gone up with the price of cotton.

Q. Does he not make at least 100 per cent profit on the cost of the bagging and ties under the square bale system?—A. I do not think he does.

Q. I think you will find that he makes 100 per cent profit on the bagging and ties on the square bale; he makes almost the premium you offer on the round bale. He loses that on the round bale system.—A. It is very strange then that the farmer should patronize the round system at all, is it not?

Q. Yes, I think it is.—A. As a matter of fact, we do not require the ginner to dispense with his square bale press. It is left in place, and the round bale press is put in the same building, and he gives the farmer his choice as to the round bale or the square bale. The farmer hauls in 1,500 pounds of seed cotton. He gins it, has it put up in the square bale, pays the ginning charges, sells the cotton. He does the same thing with the round lap bale, pays the ginning charge and the 20 cents per 100 pounds royalty. He counts the money derived from the two systems and finds he has more money for the cotton put up in the round lap bale.

The compress people always figure on the bagging and ties, figuring against the round bale. That is the test that you can not figure against. The farmer does his own figuring on that. That is the actual test of the two systems.

Q. Does the round bale enjoy the compress rates of freight?—A. I think it does. I think, however, it should enjoy the commodity rates.

Q. Have you experimented and proven to your satisfaction that more pounds in the round bale condition can be loaded into a car than of the compressed cotton?—A. Yes, sir; beyond any doubt.

Q. You think that fact is established?—A. No question about it. If you take Oakland, Miss., 40 or 50 miles below here, we had a press put in there last year and operated. You can take 50,000 pounds of cotton in the round lap bales and put it in 1 box car and the mill men in the East break the seal. It does not have to go to Memphis to be compressed and sampled, weighed in there, reweighed, and resampled. Take the same number of pounds in square bales: That would be 100 bales weighing 500 each. It takes 4 box cars of the same size and capacity to bring that 100 bales to Memphis to the compress. After it is landed here it is unloaded, trucked into the compress shed, insured, compressed, loaded back into the car, and it then takes 2 cars to carry that 100 bales or 50,000 pounds to the Eastern mills. You have to use 6 cars in handling that 50,000 pounds of cotton, while in our system we use 1 car right from the farm to the mill.

Q. You say the American Cotton Company guarantees the grade of cotton put up under your system. They guarantee the honesty of the ginner?—A. We have a contract whereby the ginner guarantees the American Cotton Company against false packing.

Q. If one-half, two-thirds, or three-fourths of the crop was put up by the American Cotton Company's system would it not become a trust and monopoly?—A. I do not see why it should.

Q. If that became a universal way of handling cotton no one could put up cotton in the round-bale system except by paying tribute to the American Cotton Company?—A. That is right.

Q. It would, therefore, become a trust if they controlled the manner of handling cotton. They will not sell presses?—A. They will sell the presses.

Q. Assuming that one-half or three-fourths of the cotton is put up that way, and suppose the spinners want it that way, the planter is under tribute to the American Cotton Company for \$1 a bale?—A. Yes, sir; 20 cents per 100 pounds.

Q. Would they not become a gigantic monopoly?—A. No, sir; it can never get anything beyond 20 cents per 100. They can not control the cotton crop.

Q. Once they establish the fact that that is the way to put up cotton and convince the buyers that they want the cotton put up that way they can change the terms of the lease and make a higher price?—A. No, sir; the contracts are for the life of the patent. They could reduce it, but could never make it any higher. The only way it could be a trust would be for the cotton company to make a contract whereby the farmer would be forced to sell them all the cotton. There is nothing in the contract that requires the farmer or ginner to sell a single pound of cotton to the American Cotton Company.

Q. What is the capital of the American Cotton Company?—A. \$7,000,000.

Q. Who is president?—A. John E. Searles.

Q. He was formerly treasurer of the American sugar trust?—A. He was treasurer of the American Sugar Refining Company.

Q. Connected with Mr. Havemeyer in the sugar business?—A. Yes, sir.

Q. As treasurer of that concern?—A. Yes, sir.

Q. That is commonly known as the sugar trust, is it not?—A. I think so; yes, sir.

Q. Let us assume that the American Cotton Company's bale will average 500 pounds; assume the crop is 12,000,000 bales, and assume that the American Cotton Company controlled the baling of 9,000,000 bales. That makes an income to the American Cotton Company of \$9,000,000?—A. Yes, sir. If they have increased the value of that 9,000,000 bales \$1.50 or \$2 a bale by this new process, they are entitled to it, are they not?

Q. You think they are dividing with the farmer?—A. Yes, sir. The farmer is the only man we figure with at all.

Q. If they make \$9,000,000 under their capitalization, I suppose they could declare a dividend of 150 per cent?—A. Yes, sir. The round bale is the only competitor that the square bale has. We have never located a round-bale press at any point where it did not raise the price of square-bale cotton from one-fourth to one-half cent per pound. That fact can be proven beyond question by the farmer and ginner.

Q. How was that brought about?—A. The city cotton buyer has an arrangement with some local merchant generally, or in large towns they have special

buyers to buy cotton and ship into Memphis. They are given limits every day—what price to pay during the day. They pay these buyers, I think, 50 cents a bale commission—perhaps 25 cents. Some are paid a salary. When the round bale starts up and puts a premium on, it raises the price of cotton. The Memphis cotton buyer telephones his agent raising the limit a quarter of a cent per pound, and in many cases one-half cent per pound. They have to do that to get any square-bale cotton at that point.

Q. Does that lead to any increase in the price of round bale? Do they still keep the price 45 points above the price of the square-bale cotton?—A. Not always.

Q. I understand they guarantee 45 points above the price of square-bale cotton?—A. Yes, sir.

Q. You have supposed a case where he telephones down and advances the price a quarter of a cent?—A. We have to increase to stay in the market.

Q. You are satisfied with 20 points advance?—A. If he raises his limit we have to raise ours.

Q. Proportionately, a quarter or one-eighth, possibly?—A. We could not do any business with one-eighth above.

Q. You do not always keep 45 points above?—A. Not always. Where there is a stiff fight made to shut the round bale out, and they get the price too high we let them have it until they get tired of it.

Q. Then you do not always carry out your contract or agreement of 45 points above?—A. Yes; because the prices are based on quotations of the regular cotton market. Memphis territory prices are based on Memphis quotations. Because a man comes up and raises the price one-fourth of a cent at Oakland, that particular case does not change the market quotation in Memphis.

Q. It affects the individual seller of cotton at that point. He has paid the American Cotton Company \$1 a bale. He has put up his cotton in the round bale under a guarantee that he is to get 45 points above the—A. (Interrupting.) Memphis quotations.

Q. Then you do not carry out the contract?—A. Yes, sir; because the contract is based on market quotations and not on speculative prices.

Q. The man that is putting up his cotton in round bales does not receive \$2.25 above the square-bale cotton, because he may not get more than 20 points above—hardly get his money back?—A. Whenever he does not get his dollar back he does not patronize the round bale further.

Q. Of course, if he does not get more than his dollar back there is no inducement for him to use the round-bale system?—A. I have one cotton buyer here that used our presses last season. This man buys for Eastern mills; he is an exporter, and I suppose he ought to know his business. He handles cotton both for our spinners and for foreign spinners. He also owns plantations and country stores. He was so well pleased with the round-bale business last year that he is going to put in 20 gin plants this year as an investment, with round bales.

Q. We had testimony yesterday from a cotton broker who buys 150,000 bales of cotton. He has instructions from customers, both East and foreign, to avoid the round bale.—A. Well, that man is interested in a compress, and that same man is now trying to make arrangements with me to handle the round-bale cotton in this town.

Q. He gave testimony that he had instructions from the spinners on the other side?

The WITNESS. Did you ever try the round bale?

Mr. SMYTH. No.

The WITNESS. You are behind the times.

Mr. SMYTH. I am not willing to take a man's guarantee 600 miles away.

The WITNESS. The only trouble we have had with round bales this year is that we can not get enough of them to fill our orders.

(Testimony closed.)

MEMPHIS, TENN., March 23, 1900.

TESTIMONY OF MR. JOHN W. ELDRIDGE,

Hillhouse, Miss.

The subcommission of the United States Industrial Commission met at the Peabody Hotel at 9.15 a. m., Senator Kyle presiding. Mr. John W. Eldridge, Hillhouse, Miss., was introduced as a witness, and, being duly sworn, testified as follows:

Q. (By Senator KYLE.) State your full name and address.—A. John W. Eldridge, Hillhouse, Miss.

Q. And your business?—A. I am retired from the sphere of active life. I am 75 years old. I have been a great deal in public life—foreign countries, as consul, traveling a great deal—and have spent a great deal in seeing progress—

Q. (By Mr. SMYTH.) Are you a native of Tennessee?—A. Born here 75 years ago.

Q. Born in Memphis?—A. Middle Tennessee. I have a brother here, Judge Eldridge.

I see your commission wish to know something about the negro—his condition in the days of slavery and his condition since that time, both educational and moral.

Q. (By Senator KYLE.) Those are very important facts, and what can you suggest for improvements?—A. I begin with the fact, gentlemen, that I have been associated with the negro all my life. Before the war I was a considerable owner of slaves myself. I know his character, his characteristics, his nature, I think, and his possibilities. At the present time I think there has been a very great advance—in the last 5 years. In truth, the more you get the negro out of politics—you understand, the more we can get him away from public assemblages and distract his mind from that—the faster he improves; he gets better; he gets more in harmony with his surroundings, and I think in the last 5 or 10 years I have seen a gradual advance. I have been a great deal on the plantation down there in Mississippi. My son has a thousand employed, I suppose, and I mix with them a great deal, and I think the negro is improving. I sit out there every Sunday morning right in front of the big Baptist Church which my son gave them—they have got a lodge in the upper story—and see men and children and women in that church all dressed as clean as white children here in town. It is wonderful the interest the mothers seem to take in their children in the way of dressing them. They are going dressed a great deal better than formerly. We sell goods down there at the plantation. My son has 2 stores with a large quantity of goods, and we buy as nice goods there and sell as nice goods to the negro; and the quality of goods many of the negro men and women buy when they come in there is very good. They buy the very best class of underclothes, \$3 to \$5 a suit, real lamb's wool. They buy the best hosiery, many of them—not all of them. Of course, in society of all kinds there are leading men and men who will lead the way. There are many leading men amongst the negroes who have much influence. Now, there is another class of negroes, generally coming from Carolina, and back in that section, and I do not find they are as far advanced as our Mississippi negroes. When they have been with us several years, they have been improved. Many of them stay with us 5 or 10 years. My son has some who have been with him, I suppose, 10 or 15 years who came originally from these States, and I find they have improved in the course of 10 or 15 years. Some of them have lived on a very small amount of money.

Q. (By Mr. SMYTH.) The conditions you are referring to when you say "down there," you mean in the delta?—A. Yes.

Q. Are the wages better there—the income of the colored man larger in the delta than in the hill country?—A. Yes.

Q. Gets more money?—A. Yes.

Q. How are the school facilities?—A. They have more in the bottom than in the hill country.

Q. Do you think the condition of the negro in the delta district is better than in the hill country?—A. I think it is far better in the hill country. They have an easy time of it on these old hills and they work just to suit themselves, and they don't care if they only make 1 or 2 bales of cotton. I am acquainted with the conditions in the delta; that is, as far as my information goes; I am familiar with the wages in the delta.

Q. Now this condition you speak of, as existing on your son's plantation, is that general among other plantations in the delta?—A. It is universal, pretty much. The planters have all become very much alike. Now, some gentleman before you yesterday, I believe Mr. Norfleet, stated that the negroes have gotten so they demanded of the landlord that they must rent the land. My son never was taken by that new process until this year. He made a great deal more money by working the plantation on shares, because if a man made any he got half, and he did all the work; he furnished the mule and furnished the tools etc., and land, and he got half, but as it is now he rents the land say for \$5 or \$6 an acre, and that is the end of it.

Morals; that is another very important thing as to what the negro race is doing; that does not read as well as education; of course there is a diversity in that as

in everything else. Some are strict in morals. I find this, however, though I am a little ashamed to confess it, that they are getting further away from the white men.

Q. Is the white men getting away from them in that respect?—A. Yes; don't work them anything like they used to.

Q. We had testimony just now that the white man ceased this on account of syphilis, etc.?—A. Not only that, but because the negro will not let them have it. The negro buck will go down and will stay right around them. It is not a matter of fear of disease as much as that fact; you can not get one of them to go into a store. If a girl goes into a store 4 or 5 negroes will come in and stand around; but the races are further apart in that line. There is one form of evil, that is, they take up with each other. I say the negro fellow will come down there on the plantation and he will say, "Mr. —, if I had a wife I would go to work." "Well, there is a woman up there that just came down from North Carolina; just go and take one of them if you want to." He goes over there and he agrees to it; never saw her before in his life; they just go together and they will stay together and never get a marriage license. But the African preachers are trying to control that; they are turning them out of the church.

Q. Are the preachers moral down in your neighborhood?—A. They say they are not; I do not know. They say they have more contributions almost than any one profession; they have access to all negro families.

Q. In the absence of the men?—A. They have wonderful influence with the women. The negro is influenced largely by his pastor; by the preacher.

Q. By the negro preacher?—A. Yes.

Q. He visits the family in the absence of the men?—A. Yes; or he goes around among the members while the employees are at work. I saw 3 or 4 down there who came during the conference that extended all over the South—the preachers through my district there—and they are very well-behaved men. I always speak with them, shake hands with them sometimes, when they show a disposition to know me, talk with them, and try to make them feel as though they were at home. I want to influence them as well as I can.

Q. Are there many illegitimate births in your section down there?—A. You call them illegitimate where they are not married, but many of the women are not married who have lived with the same man for years.

Q. Do they change women often?—A. No, sir; only a certain class of reckless negroes and women of the same character. They will just take a new one every 6 months and part if they get mad at them, and they will get a new husband or wife in a week.

Q. The law is not invoked to prevent that?—A. No, sir; it don't amount to much. We have nothing to do with their wives or anything of that kind. Now, there has not been on my son's plantation—he has from 4,000 to 8,000 acres in cultivation—and there has not been any such thing as difficulty between the white men managers and negro laborers of any kind.

Q. And you do not interfere with their wives?—A. No; we do not interfere with them, and if a woman comes into a store, and there is a white man standing around, there will be a half a dozen colored men in front of the store waiting for her. I think their morals are in better condition, their education is improving, and they are going to be more respectful in their manner. Many of them can read and write very well. I am postmaster there at Hillhouse and have a great deal to do with their letters, and I find nearly all of them improving. The negro is peculiarly created; as distinct from the white man as a mule is from a horse. He will carry his characteristics with him to the grave and to the heaven, if there is a heaven for the negro. But he is a negro, speaking kindly. He is grateful; he has no animosities; he has no revengeful spirit as a white man has; he is the best labor we could have in the South. Altogether he is the best labor in the United States. I have been all over Europe and several countries, and I have never seen labor as good as the negro. Taken away from politics—I know you are Northern men—

Mr. SMYTH (interrupting). No; I am not.

The WITNESS (continuing). Take him away from politics and let us do all we can to educate him and help him along, deal with him fairly and squarely, which I think we do as a general thing. If we have got to have him here, let us have him in a way—possibly give him liberties and rights and all that—but I find that he does better since Mississippi has limited the franchise and cut off all that turmoil and strife of election.

Q. (By Mr. RATCHFORD.) On that point, does the negro share in the right of franchise to-day equally with the white man?—A. Well, some of them do, sir, just according to the state of advancement. There are a good many like we are, that want to be politicians.

Q. (By Mr. SMYTH.) What is the law of Mississippi with reference to suffrage? What are the qualifications in Mississippi for a man to vote?—A. I should like to be very careful in stating that. He has to be qualified from several points of view; among them is a certain amount of education, enabling him to read and write part of the constitution of the State—of the United States. He has to know the meaning of that paragraph, and others besides—some others besides.

Q. Any property qualifications?—A. No, sir.

Q. Simply an educational one?—A. We have a good many negroes who are buying lands. Yes, large numbers of them, going up to 5 or 10 mules, 40, 50, 60, 70, or 80 acres of land. That class of men don't care much about politics or anything of that kind. They are simply going to start that way to make money, and some of them have credit here in town and can buy a barrel of bacon or barrel of sugar or whatever they want.

Q. Do you know whether the number of illiterates is on the increase or decrease?—A. I think, as far as I can say, in the country districts this is on the decrease.

(Testimony closed.)

MEMPHIS, TENN., March 23, 1900.

TESTIMONY OF MR. MAT W. MOSELEY,

Cotton Dealer, Memphis, Tenn.

The subcommission of the United States Industrial Commission met in the parlors of the Peabody Hotel at 9.15 a. m., Senator Kyle presiding. Mr. Mat W. Moseley was introduced as a witness at 2.23 p. m., and, being first duly sworn, testified as follows:

Q. (By Senator KYLE.) What is your name and address?—A. Mat W. Moseley, 274 Front street, Memphis, Tenn.

Q. What is your vocation?—A. Cotton dealer.

Q. That is, you buy from the farmer, do you?—A. I buy from anybody who will sell to me and sell to anybody who will buy from me.

Q. What would you call a broker?—A. A broker strictly buys on orders, you might say; but I buy and sometimes carry a stock of my own and sell when I see proper.

Q. So you come in contact with the farmers themselves?—A. No, sir; I buy all my cotton in Memphis.

Q. You know little of the condition of the farming class engaged in raising cotton?—A. Yes, sir; I have very little positive information.

Q. The cotton you get comes from what region?—A. I buy it here in Memphis or the Memphis district.

Q. Mostly Tennessee cotton?—A. No, sir; Mississippi and Tennessee cotton.

Q. Have you been engaged in plantation cotton raising?—A. No, sir; I know nothing of the plantation business.

Q. What can you say as to the prices of cotton now as compared with former years?—A. This has been a most remarkable year in the price of cotton—a marvelous season, the like of which we have not had in many years.

Q. So the cotton brokers and factors and all have been prosperous?—A. Yes; I think our country here is in better condition than it has been for a number of years. I think if we could have another 10,000,000-bale crop and get 10 cents for it everybody would get out of debt and have something left. Many mortgages would be relieved; people have paid off a great many.

Q. People have paid off a great many mortgages?—A. Yes, sir; I think our planting section here will be in a position where they will not have to borrow as much money as heretofore and not be so dependent on the commission men.

Q. You are not in a position of a factor who is loaning money to the farmer?—A. No, sir.

Q. What has been the range of prices for the last 10 years in cotton?—A. I believe statistics will show there has been a fluctuation of from one-fourth of 1 cent to 2 cents a pound from the beginning to the close of each season, sometime intervening between the beginning and the end of the season. It will either go up or down.

Q. Between what months?—A. We claim the year begins the 1st of September and closes the 1st of September. As to what time these variations would occur it would be difficult to say, except from statistics, which are kept and filed away.

Q. When is cotton generally the lowest price—what months of the year?—A. Well, I believe, as a rule, it would be difficult to say; but speaking from the impression on my mind, I think the averages would show sometime between the latter part of November and the 1st of January, when the bulk of the crop is being marketed and the showing up, the receipts, are largest, and when, as the people who consume this cotton can see a great deal of it, of course they are in no hurry to buy it; for that reason it is what we call a slow market, a depressed market.

Q. It is at that time the farmers are compelled to sell, as a rule, is it not—during the fall?—A. I suppose that is so. They have a great many obligations out that have to be paid and that compel them to unload their cotton.

Q. What percentage turn off the crop during the fall months?—A. I could not say.

Q. In times like this more could hold over for better prices, you think?—A. That is the great advantage our country would have. The great trouble has been that the planters and farmers here have been compelled to sell their cotton without regard at all to price. It has to be sold for whatever it will bring. For instance, a man has advanced money on a crop, and the farmer ships his cotton here, and when it arrives here, if he has not positive instructions about selling or holding that cotton, as a rule he sells it. The great trouble with the cotton market here is that during September, October, and November the cotton is rushed into the market in immense volumes.

Q. If it could be more evenly distributed during the year the farmer would realize a better price?—A. I think beyond question.

Q. Are you aware of any movement on foot to enable the farmer to store his cotton?—A. I do not know that I am except through the newspapers.

Q. Cotton is very good security?—A. It is considered the best.

Q. Suppose there were country warehouses built?—A. You can take our own town—if the people here, some good strong concern, would build an immense bonded warehouse (we have nothing of the kind) that would give the people who raise cotton cheap storage, cheap insurance, and other advantages, with a good compress attached to this plant, it would be a grand thing for us here. There is nothing of the kind. We have a great deal of storage capacity, but the cotton has to be drayed into the warehouse, drayed from the warehouse into the compress, and it is a useless expenditure of money.

Q. (By Mr. SMYTH.) Are the warehouse receipts taken as collateral by the banks for loans?—A. Yes, sir.

Q. There is nothing to prevent the farmer placing his cotton in the warehouse and borrowing money on the receipts?—A. Yes, sir; that is done all right.

Q. You think a bonded warehouse would have a cheaper rate of insurance?—A. That is right, and would enable him to get cheaper storage, and cheaper insurance, and give a higher valuation to his receipt, as a matter of course.

Q. Being bonded, the warehouse receipt would be taken more readily by banks and possibly at a lower rate of interest?—A. Sure.

Q. (By Senator KYLE.) What rates of interest are charged the farmers by the banks?—A. Now, I do not believe the farmers borrow much money from the bankers. They get the bulk of the money from the commission man, who stands between them and the bank.

Q. (By Mr. RATCHFORD.) What rate is charged by the commission men?—A. I could not say. That is a matter of contract.

Q. (By Mr. SMYTH.) What is the usury law in this State?—A. Six per cent.

Q. (By Senator KYLE.) Anything over 6 per cent is usury?—A. I think so; yes.

Q. (By Mr. SMYTH.) Is much cotton brought into Memphis by railroad?—A. A great deal.

Q. Are the rates high locally?—A. There is a question. It has been a question that has worried the cotton people here considerably, and a great many think there are special favors granted to some people—local the cotton in and reship, and they get—

Q. (Interrupting.) They rebate all the local rate paid in on the cotton?—A. Yes, sir. The cotton may be hauled in here free of charge, provided the road gets the cotton going away.

Q. Used, as the exporters say, as a common point?—A. Yes, sir. I would not like to make the statement. I say there is a feeling of that kind here. There has been no way on earth to locate it.

Q. I suppose the system is the same as in other places where a man is enabled to gather his cotton at small stations, and the road will take it out and rebate the freight paid from these small stations to the compress?—A. Yes, sir.

Q. And no one enjoys that privilege but the exporter shipping out?—A. Yes, sir; that is right.

Q. The effect on you or on anyone buying in Memphis who has to pay that freight in that way, you think, is a discrimination and gives an unfair advantage to the exporter?—A. That is right. Another thing here; a cotton shipper in Memphis cannot route his cotton out of this town.

Q. Explain that. I understand there is a physical division of cotton here, that each road is allowed a certain percentage of the cotton taken out of Memphis, and if the shipments exceed that amount, it has to turn over the surplus to the other road.—A. That is right.

Q. And as a shipper you are unable to positively direct by what road your cotton shall go; you do not know whether that road has received its proportion or not?—A. That is right. Until a few years ago, perhaps a year or some such matter, we had what we called fast-freight lines here. Their agents were here and they would make rates. They would give you an export rate to Liverpool—any export point. They can not do so any more. A shipper is not allowed to go to that man now and offer him cotton for shipment because the initial lines dictate the road that cotton must go over from here to its point of destination. We think as shippers that they have cut off a very splendid competitive arrangement which enabled us to get very much better rates.

Q. If you were shipping 500 bales to Liverpool you can not say whether it is to go by Savannah or Charleston?—A. You can not. You give him the cotton, your compress tickets, and the point of destination, and he hauls the cotton the way he wants it to go. A great deal of business has been lost by Memphis shippers. For instance, take a large spinning establishment like Knight Brothers, of Providence. As a rule, they want their cotton shipped over certain lines for reasons of their own, and they will tell you if you can not ship that cotton over that road to pass the order. We just can not do it from here, and the business goes elsewhere.

Q. You can not enforce your directions as shippers?—A. No, sir.

Q. (By Senator KYLE.) You are not in favor of pooling interests with the railroad?—A. I do not think so. I am against anything that is opposed to the interest of the town and the business of the town, and I think that is.

Q. What are the receipts of cotton at Memphis?—A. Last year we received about 770,000 bales, I think.

Q. That cotton was sold here?—A. I would not say all. That was gross receipts. There was perhaps 50,000 bales more that passed through here that did not stop in Memphis.

Q. (By Mr. RATCHFORD.) You are speaking of bales?—A. Yes, sir.

Q. (By Mr. SMYTH.) There is no competition of water rates either by Cincinnati or New Orleans for points East or the Continent?—A. There seems to be a pretty well understood arrangement and agreement here now that there is not much cutting of rates. They are standing by their agreements pretty well. There is just a little difference in shipping by river in the insurance proposition, 5 or 10 cents a bale, perhaps. There is that much in favor of the river.

Q. Against that you have high insurance to pay?—A. I do not know that you do. You see a great deal of the cotton that goes East is shipped here by people who have their own representatives in the East, who insure their own cotton, and it is rather difficult to tell what advantage they do get out of it.

Q. It has been stated here that the river insurance is higher than the railway insurance; why is that?—A. Would you not rather have a rail risk than a river risk?

Q. Is there more danger from sparks?—A. You know the Mississippi is a pretty rough stream, and there are a great many snags, and other steamboats; and we have lost more cotton on the river than we have by rail. They consider the risk better and safer by rail than river.

Q. How is it with the traveler? Are there not fewer lives lost by boat than by rail?—A. A man could probably take better care of himself than a bale of cotton.

Q. How is it on the ocean?—A. You take the river rate to New Orleans; if you want to ship a shipload of cotton from here to Liverpool, I think the insurance companies would charge more going down the river. The additional risk from here to New Orleans would be unreasonable as compared with the regular ocean rates, and very little of it has been taken from here in that way.

Q. What is the actual difference in shipping by water and by rail as regards insurance?—A. To save my life I could not tell you what the difference is. As I say, I have shipped cotton by river to people in the East, and would ask the question whether there was any objection to shipping the cotton by river, they covering their own insurance, and there was no objection.

Q. If you ship to New York City or Boston by water, it has to be transferred to the ocean-going steamers at New Orleans?—A. There is a great deal of cotton goes from here to Liverpool via Boston.

Q. To the Massachusetts mills, I mean.—A. What is the question?
 Q. Do you have to transfer the cotton from the barges to the steamer at New Orleans?—A. It goes by Cincinnati.
 Q. Suppose it goes the other way?—A. I never heard of it going that way. They could not afford to ship around that way. You see they have the rate from here to Cincinnati by river, and the river rate is a little cheaper than the rail rate. I do not know what the difference is, but not over 5 or 10 cents a bale.
 (Testimony closed.)

CHARLOTTE, N. C., March 15, 1900.

TESTIMONY OF MR. B. O. DUNCAN,

Farmer, Newberry, S. C.

The subcommission of the United States Industrial Commission met in the rooms of the Southern Manufacturers' Club at 10.12 a. m., Mr. Smyth presiding. Mr. B. O. Duncan was introduced as a witness, and, being first duly sworn, testified as follows:

Q. (By Mr. SMYTH.) Will you give your name?—A. B. O. Duncan.

Q. Your place of residence?—A. Newberry, S. C.

Q. What is your occupation?—A. I look after a little farm, but my principal occupation is student and writer of papers on political and economic and financial questions.

Q. The commission have understood that you have partly prepared a paper expressing some views on industrial conditions that you would like to submit to the commission, but that you prefer to complete it and then send it to us.—A. Yes, sir; I did not know in time, until your secretary, Mr. Sackett, wrote me from Washington the other day, and his intimation was that I might write, but I did not have time to finish up my writing until it was time to come.

Q. You prefer to write it?—A. I prefer doing that because I can do it with more care.*

Q. (By Mr. RATCHFORD.) Are you interested in manufacturing?—A. I am interested in industrial matters in general.

Q. Not personally interested?—A. No; we have quite a successful cotton mill in Newberry that I am familiar with.

Q. (By Mr. SMYTH.) You are not connected with the management or employment of labor?—A. In no way, except in the employment of farm hands to some slight extent.

Q. (By Mr. RATCHFORD.) There is no objection to Mr. Duncan's sending on his statement, which statement, it is understood, is sworn to?—A. Yes, sir.

Mr. SMYTH. You will prepare that statement, attach your affidavit to the bottom of it, and send it to Mr. Sackett at Washington.

The WITNESS. Very well.

Mr. RATCHFORD. With the request that it be incorporated in your testimony.

The WITNESS. There is one point which I wish to speak of—some erroneous statements in the testimony yesterday as to the relative numbers of the two races in South Carolina. It was spoken of as though it was 2 to 1. That is not correct. It is about two-fifths to three-fifths; about 400,000 whites and a little over 600,000 negroes. Several of the witnesses referred to it as though it was 2 to 1. It is bad enough as it is, but it is not as bad as it was represented. There is one other point that was referred to—that is, the question of the migration of the negroes and sending the negroes out of the country. Colonel Orr very emphatically referred to his opposition to it. I should like to say that I entirely agree with all he said on that point.

Q. (By Mr. RATCHFORD.) In that connection he was asked as to his opinion on colonization.—A. Yes.

Q. It does not follow that the colonization of the negro means the sending of him out of the country. We have some people who favor colonizing him in our own country.—A. Yes; I know that. We certainly have a surplus of negroes in parts of South Carolina, and it would be well to send out a colony of these, perhaps—that surplusage—but nothing like the idea that has been advocated by some, especially by ex-Senator Butler. While I generally agree with General Butler's ideas, on that point I do not agree with him at all. I think the negro is a necessity in the South as a farm laborer; we have no other in our State.

*The statement referred to was not furnished on account of the death of the witness.

Q. (By Mr. SMYTH.) You mean Senator M. C. Butler, of South Carolina?—A. Yes, sir.

Q. (By Mr. RATCHFORD.) You think if the negro was sent out of the South the farms would to some extent go to waste?—A. They would temporarily, because we have not the farm labor in South Carolina outside of the negro.

Q. Would not the readjustment of labor regulate that as it does in the North, for instance?—A. In course of time it probably would, but it would not immediately. I think it would take a good while.

(Testimony closed.)

CHICAGO, ILL., March 27, 1900.

TESTIMONY OF MISS EMMA C. SICKELS,

National secretary of the National Pure-Food Association; also secretary of the National Domestic Science Association.

The special subcommission met at 7.15 p. m., March 27, 1900, in the Auditorium Hotel, Chicago, Mr. Clarke presiding. At that time Miss Emma C. Sickels was sworn as a witness, and testified as follows:

Q. (By Mr. A. L. HARRIS.) You may state your name, your post-office address, and the name of your association, and the official position that you hold in the association.—A. Emma C. Sickels, 5435 Washington avenue, Chicago, secretary of the National Pure-Food Association, and also secretary of the National Domestic Science Association. These are two distinct corporations. They are two affiliated bodies.

Q. You may make your statement now in your own way, touching upon such points as you desire.—A. A Congressional report of an inquiry which was made a few years ago, into the unbalanced industrial conditions, gave as one of the causes, the crowding of women into all fields of men's work and the neglect of the home. It is evident, therefore, that inquiry might be well made into the reasons for this desertion of the home and the attraction which men's work has for women. Statistics show that in the colleges, universities, secondary and primary schools, the ultimate object seems to be for some form of professional life. Comparatively small opportunity is given for education in performing to the best advantage, the normal, healthful vocations of life, such as agriculture, mechanics, the best methods of conducting a farm or a business, or the best methods of conducting a home. In other words, education is designed to meet abnormal or diseased conditions of the individual or society, while the means for best promoting the normal conditions are neglected. Abnormal conditions are actually developed by the facilities provided for meeting them. Normal conditions suffer from neglect, and the social and industrial balance is disturbed. This is especially true in all lines of women's work. If women wish to fit themselves for some employment, the only opportunities for a thorough education lie in some field of men's work, some profession, some mercantile or mechanical industry. I can say from my own experience that it is easier for a woman to be a physician, a lawyer, a chemist, or a soldier than it is to be a cook, in the broadest sense of the word. It is easier to learn about anatomy, botany, the heavens above, or the animalculi in the deep sea than it is to learn about the principles of the combinations of food materials and the right use of foods for the best results to the individual and in the family. There is no place in which domestic science—the knowledge of daily living—can be taught in the systematic way in which almost every other science can now be taught.

For twenty years I have been trying to find some opportunity or some opening where I could make as thorough and systematic a study of the laws for the preservation and continuance of health as are now afforded in the schools of medicine for its restoration. In my own experience, finding that the lack of the right food, when I was a school girl, was the cause of a threatened invalidism for the rest of my life, I determined to make a study of this as a science, believing that it was a matter of the widest importance to all individuals. I have found no place, in any school or university, where the simple necessary rules of life are efficiently and effectually taught. After having learned of the report which was made by the Congressional committee and of the importance of woman's relation to this industrial condition, it seemed to me that the legislation which is now being considered in reference to other industries should also apply to this. I have found that it was a new subject to nearly all of the gentlemen to whom I have proposed

it. I have found also, that it seems only to need to have its importance presented to them to have their ready cooperation.

Last year a subcommittee was appointed from the United States Senate Committee on Agriculture to consider the subject of a systematic study into the methods of preparing foods, to be made in the different agricultural colleges, which are now more or less equipped for that purpose; to have these investigations scientifically carried on, and report to the Department of Agriculture. Through this Department these reports would be systematized; the best work of the different colleges could be concentrated, and reports sent out for the use of the different schools and colleges and for distribution in the homes.

There are many colleges which are now giving attention to this subject—a study of the systematic preparation and use of foods. These are handicapped by lack of funds, and are even more handicapped by lack of system. By the carrying out of this plan, which received the cordial approval of the Senate committee, the work which is now being done in a limited way can be broadened and can be made available for the use of the homes throughout the country.

It was with the idea of showing the direct relation of this educational to this industrial problem, which is becoming so important in the social and industrial conditions, referred to in the beginning, that this matter has been brought before the Industrial Commission for your consideration and investigation of the different lines and of the different facts which have come within our observation, with a view to learning on our part in what way legislation can most fully bring about the best knowledge, by industrial education, in the preparation and use of food. In direct connection with this is also the national legislation for uniform standard of food. These are the subjects which the representatives will treat to-night.

Q. In what States have you departments or communications with agricultural colleges?—A. We have not departments, but the different colleges themselves have established departments in Minnesota, Iowa, Ohio, Illinois, Kansas, and I do not know what other States. (To Professor Davenport.) Do you know in what other States?

Professor DAVENPORT. South Dakota and Michigan.

Q. (By Mr. A. L. HARRIS.) Are these schools in a flourishing condition?—A. They are in a flourishing condition so far as the opportunity affords, showing the recognition of the necessity, but they are handicapped by the lack of system and lack of funds.

Q. Do you desire to have other States inaugurate the same system in their agricultural colleges?—A. Yes; and some uniform system should be developed which will be applicable to all of those which are established and those which will be established.

Q. You desire to have some national legislation along this line?—A. That is the purpose. That was recommended by the Senate Committee on Domestic Science last winter.

Q. Have you anything further now that you desire to state?—A. I have nothing further.

Q. (By Mr. KENNEDY.) In the public schools in some cities the girls are given lessons in cooking once a week or twice a week sometimes. Is it your idea to have anything in connection with this science of yours taught to these little children in the cooking schools or the public schools?—A. Yes; that would naturally follow from this work in the universities. It would extend throughout the educational system of the country.

I should speak of a class I had in the Social Settlement, where the women were the wives of laboring men who could not afford the car fare to come, but walked some of them a mile through a blizzard, bringing their own utensils with them; and they said it was "such a great thing to get up in the morning and know how things were going to turn out." It seems as if the means of meeting this should be as extensive as the need, which is an underlying necessity, I think, throughout the whole social system.

In our domestic science work, which was the first phase of this movement which was organized, we found that there were many others who were working along the same line, not knowing of one another's work. A conference was called January 29, 1897. A number who were interested in different lines responded, and from that grew the National Pure Food Association, of which Dr. Jones is the president.

Q. (By Mr. CLARKE.) You spoke of lack of text-books or other instructive writings on the subject which you experienced in your school days. Has that want been supplied to any extent?—A. It has not. I have here a letter, from the president of the Illinois Domestic Science Association, in which she says that the women have organized throughout the counties of the State in connection with the teachers' institutes. They have obtained the literature supplied by the Department of

Agriculture upon this subject, and all others which they can find available, but they find so little of practical use in them that it is very discouraging.

Q. Some hygienic writing will be necessary as a part of the text-books or the literature on the subject?—A. Yes; and this phase of the subject is being taken up by the different schools in agricultural experiment stations, showing the nutritious effect of food.

Q. Have you gathered the pamphlets or circulars on the subject which have been put out from time to time?—A. I have, and studied them carefully. I am supplied regularly with each new publication as it comes out from these experiment stations by Dr. True, with whom I am personally acquainted. Dr. True is in charge of this department in Washington.

Q. Are you familiar with the temperance text-books which have been issued to the schools in some of the States?—A. No; I am not. It has been my stand and argument with the temperance women that lessons in nutrition of food, and the useful application of that knowledge of nutritious food, would be much more effective than lessons on a stimulant, the use of which in most cases is due to the lack of nutritious food. So I have paid comparatively little attention to that phase of the question.

Q. Have any steps been taken by the Pure Food Association toward providing suitable literature on the subject?—A. The Pure Food Association has worked through and with other organizations in the line of this national work, feeling that it would be so much more effective and broader to reach those who are already widely equipped.

Q. (By Mr. A. L. HARRIS.) Is the Agricultural Department at Washington doing anything in the way of nutritious food; making any appropriations?—A. Last year an appropriation was made of \$15,000 to investigate into the nutrition of food. I think the argument will hold which I gave to Secretary Wilson, that although he might know the exact amount of carbohydrates and proteids in the foods set before him, if they were not prepared correctly he would not appreciate his dinner very well; showing that in practical application the methods of preparation have the greatest value and importance. These investigations which are now made are almost solely as to the nutritious effects of the food; the so-called balanced ration of individuals.

Q. Has the Secretary of Agriculture made any recommendations for appropriations along the line of your association?—A. He told me that it was a subject in which he was very heartily interested, and that he would be very glad to yield to the public request; that if he took the initiative he would be accused of making requests personally which were not supported by the public; but that he would second and support any request that was made publicly for it.

Q. You understand, then, he is in sympathy with the work of your association?—A. He so told me, and he has so told others.

(Testimony closed.)

CHICAGO, ILL., May 27, 1900.

TESTIMONY OF DR. SAMUEL J. JONES,

President National Pure Food Association.

The special subcommission met at 7.15 p. m., March 27, 1900, in the Auditorium Hotel, Chicago, Mr. Clarke presiding. At 7.40 p. m. Dr. Samuel J. Jones was sworn as a witness and testified as follows:

Q. (By Mr. A. L. HARRIS.) You may state your name, your post-office address, and your occupation.—A. Dr. Samuel J. Jones, 92 State street, Chicago; physician.

Q. You may state what office, if any, you hold in connection with what is known as the National Pure Food Association.—A. I have tendered my resignation as president of it, but I have not been informed of the acceptance of my resignation. I was elected president when the association was formed, and have been the only president of the association.

Q. When was the association formed?—A. In 1897.

Q. Is it incorporated?—A. It is, under the laws of the State of Illinois, as an organization not for profit; chartered in 1897.

Q. You may state as briefly as possible and in your own way the object of the association and the cause why such an association should exist.—A. Perhaps I had better begin with the initiative which led up to the formation of this organization. In January, 1897, I with others, was invited to be present at a meeting

of the Domestic Science Association held in this city. After a discussion bearing upon the subject of food and its preparation, I was asked to express my views in regard to the discussion which had just occurred. I stated that it seemed to me that it was in the right direction, that the work they were doing was noble work, but that they had not begun at the beginning; that the old maxim, in discussing the best method of cooking a hare, was to first catch the hare. Assuming that they had gotten pure food, their discussion as to the selection of the different kinds of food and the best mode of preparation was all right; but how do you know that you have gotten pure food to prepare? It is a known fact that the best cooking can not purify impure food, although poor cooking may make very bad food out of what is pure. How do you know that your supplies that you get and that you propose to serve as pure food are such? We get them from the dealers who deal in these articles, assuming that they are familiar with their condition and that we get the best we can, and we go on that assumption. I said: The theory is all right, but when it comes to the practical application of it experience has shown that in order to make your work effective you must go back to the starting point. You must secure the pure food, then your practical application comes in well under your domestic science, which is the practical application after having secured this. The question at once arose, and was put to me: How would you suggest that we do this? You have got to reach the producer in the first place, the farmer who supplies us with our vegetable and most of the animal food, and trace it from him through the middlemen to the consumer. How can this best be done? I said, I have not given special thought to the matter, but the first thing that occurs to me is that an organization should be formed, and that back of that should be the law, which is the only thing that will secure the accomplishment of the object that you have in view. Therefore, my first thought would be to secure an organization, incorporated by the State; it can be made national in character, although the charter may be from this State. After discussing the matter pretty fully they decided to form an association and adopt the name of the National Association of Producers and Purveyors of Pure Food.

When the charter was obtained by-laws were adopted for the government of the organization. This was the name given in the original charter. We had nothing to guide us; therefore we had to grope our way along to find out what was really essential to the accomplishment of the aims of the organization. We must secure the interests of the producer, of the middleman, and the consumer, and the more we discussed it the more we were satisfied that those who were dealing in food products for profit should have no say in the management of it, otherwise our object would be defeated. Therefore two sets of membership were formed—the active members, who should not have any financial interest in it, and associate members, who were willing to contribute toward the expenses, but who should be precluded from getting control of the organization and diverting it from the object we had in view. Later, it was decided that as the name was long and that we could not take into active work in the association those dealing for profit, it was decided to change the name of the association to the National Pure Food Association, and that is the name of the organization now. The change was legally made in this State. Why this step was taken was in consequence of assurances we had from different sources, which we believed to be reliable, of the great extent of dilution and adulteration of food, making a distinction between that which simply impaired the efficiency without introducing anything positively deleterious in it, but diminishing the nutritive value of the food somewhat. I do not know whether you desire to go over these by-laws to give you an idea of what they are. I might just read a few of the principal points. [Reading.]

"ARTICLE III, SEC. 1. Every adult person of good moral character may become a member of this corporation upon making application to and being accepted by the secretary of this corporation, provided such acceptance be indorsed by the president of the board of directors; and if not so approved by the president of the board of directors, such application shall be by the secretary rejected, provided such application does not embrace any applicant for membership provided for in section 2 of this article."

That is the distinction we made between the active and associate members. (Continuing to read:)

"SEC. 2. No person shall be eligible for active membership in this corporation who is either a manufacturer or distributor of food products for profit. Except such persons may, by application to and upon approval of the board of directors, become associate members, but without the right to vote at any meeting of the association; and no such person shall be an officer or director of the said corporation."

"SEC. 3. Active and associate members shall pay such an amount of dues, payable at such a time as the board of directors herein or hereafter fix.

"SEC. 4. The board of directors may, in its discretion, name any person or persons as honorary members of this corporation, provided such person or persons shall not be of the class excluded from active membership by section 2 of this article."

* * * * *
"ARTICLE VI.—*Board of directors.* SEC. 1. The business of this corporation shall be intrusted to and transacted by a board of 9 directors.

"SEC. 2. That at the annual meeting of the corporation in the year 1898 3 of the present members of the board of directors, to be chosen by lot, shall retire, and their places be filled by 3 persons elected for a term of 3 years, and the remainder of said board shall continue in office for the succeeding year.

* * * * *
"ARTICLE VIII.—*Officers.* SEC. 1. The offices of this corporation shall consist of a president, vice-president, secretary, and treasurer, who shall hold their respective offices for 1 year and until their successor or successors are elected and qualified."

Then it goes on with the duties of the different officers, beginning with the president, and provides for annual reports, amendments, and so on. Those are the principal points in that. In discussing the matters we found that there were chemists in the city who had been connected with the State board of health and other organizations, who had given considerable time to the investigation of these articles to determine the correctness of charges that were made of the extensive dilution and adulteration of food. After conference with Mr. Harris, which I had a couple of days ago, and in which I suggested that we might be able to have present with us this evening some of those chemists who can not only give statements as to the results of their work, but present some of the articles that they analyzed, with the results. I communicated with two, and others were out of the city, whose testimony would have been valuable, but whom we could not get. Mr. Kennicott is present. He was the city chemist for the department of health for the city. He has an engagement. He is present and would like to get away, so that if I may interrupt my statement at this point, and you give him a hearing now, he might be able to present some matters that might be important and perhaps of interest to you, and that he then be excused and I continue.

(After hearing the testimony of Mr. Kennicott, the commission resumed the hearing of Dr. Jones, as follows:)

Q. (By Mr. A. L. HARRIS.) You may take up the subject where you left off, and then your testimony will appear consecutively.—A. If you will allow me to digress a little in regard to this question of adulteration of milk, it recalled a little experience during our civil war. I was a surgeon in the United States naval service in charge of the naval hospital in New Orleans. The supply of water is kept in cisterns. During the dry season the supply got very low, and the milk supply was very animated. One of my assistants got some milk and turned the can back to the milkman and said, "What proportion of water do you put in the milk?" He said he got this milk of another man, and he added: "These little wigglers in the dry season get into the cisterns and they get into the milk." So you see there are different methods of diluting and adulterating, and different adulterating substances.

In reply to a question that was asked as to whether any literature had been put out by our National Pure Food Association, a circular in this form was issued in an effort to educate the public in regard to the work that we were trying to do and to interest them, on the theory that people are most apt to be interested in those things that they know most about. It is not very long, and perhaps I had better read a part of this as covering the ground that we were trying to accomplish and explain the steps that were important, because we are now groping as was sanitary science a quarter of a century ago. When I began my professional career, we knew practically nothing about sanitary science, and what we know as sanitary science now may be considered as practically the result of the investigation of the last quarter of a century. We are going through that same thing now in regard to food for human beings. As has been justly said, the inferior animals have been taken care of, because they had a market value in dollars and cents; their owners could see directly the connection between nutrition and developing the market value and the money returns. The farmer could see that in his horses and cattle but could not see it in himself or in his family; they were a secondary consideration; they had no market value. Considering matters from that standpoint, it occurred to us that a circular somewhat of this nature might arouse attention and interest, and get cooperation. We were working without money practically paying our expenses for the privilege of working for the public; in other words, meeting expenses incident to this out of our own pockets until we thought

we should interest enough of the public that a sufficient amount of money could be contributed to enable us to put into practical working our ideas, first as to the securing of pure food, supplementing this with domestic science, as the term is understood—a practical application of this principle. (Reading:)

PURE FOOD.

"So well known is the fact that many fraudulent articles are now sold for food that no special evidence is necessary to prove that adulteration of food is a very prevalent and widespread practice; nor does it need any argument to convince one that impure food is unwholesome.

"That 'the best is the cheapest' in the long run is especially applicable to the purchase of foodstuffs. The supposed cheapening of the price of food by fraudulent adulteration is really expensive, inasmuch as it often costs the price of health itself, and in the next place the price necessary for its restoration, even when such restoration is possible.

"The adulteration of food is not always effected by the admixture of deleterious ingredients directly injurious to life and health. The impurity consists in the lowering of its nutritive value. The object of food is nutrition. We eat to be nourished. If the volume and weight of foodstuffs are maintained by the admixture of substances that, without actually and directly causing injury, yet fail to sustain life, impart strength, and repair loss; that is, if the quantity of material taken into the body does not amount to the value of nutrition represented by that quantity of that special class of food, the body will fail to perform the amount of work which is the measure of the work-producing power of that food. In that case the expenditure will exceed the income, and the health of the constitution must break down in consequence. All this is now reduced to an exact science. There can be calculated with accuracy the units of heat produced by the consumption of a given weight of carbohydrates (as sugar, starches, etc.), and hydrocarbons (as fats, butters, etc.), and the mechanical equivalent of a given amount of albuminoids (or food containing albumen, as eggs, meat, pease, beans, etc.) in foodstuffs, just as easily and as certainly as can be estimated the measure of mechanical energy from the consumption of a given weight of coal.

"Thus it is rendered apparent that only pure food should be eaten that the body may be properly nourished with the least possible effort, without unnecessary expenditure of digestive effort that tends to impair health, and without the expenditure of money for articles having less food value than they are believed to represent.

"An association has been organized and chartered to secure these economical and philanthropic ends, without capital and with no intention of financial gain. As every housekeeper and every consumer is naturally interested in the advantages which the association aims to secure, all are invited to cooperate in making the attempt a success.

"It is contemplated to establish an exchange situated in a central and convenient locality, with exhibits of all descriptions of foods tested and found to be of commendable purity, and to employ competent chemists and microscopists to analyze and report upon samples of manufactured and prepared edibles for the information and service of purchasers.

"Lectures and demonstrations on foods and cooking will be given, as well as instruction regarding the influence on the body of different kinds of food.

"Housekeepers, heads of families, and others desirous of joining the association are requested to address Miss Emma C. Sickles, secretary of the National Pure Food Association, room 346, 325 Dearborn street, for terms of membership and other information.

"MAY, 1897."

THE WITNESS. We found that in the stringency of the money market here it was impracticable for us to raise the money that was necessary to carry this out. There being no existing laws to accomplish the purpose, we thought to educate the public and arouse such an interest that we should ultimately secure both State and Federal legislation. Finding that we could not make this exchange a success, we directed our efforts through the press, through social organizations, by public lectures, and other means, to arouse the people in this city. Through the farmers' congresses and different agricultural bodies the matters were discussed, and an interest developed in that way. The domestic science organization was an advantage to them in their practical application of it, and they renewed and redoubled their energies in that direction. We continued to work until we saw the prospect of the passage of the law in this State, and a pure-food commission and officials to see to the enforcement of it. The prospect at the last session of Congress gave us hope that some law would be enacted by Congress when that would reach the result

of attempting to unify as far as practicable the State laws already enacted, and perhaps to encourage other acts, and in that way secure a control between the States where articles were manufactured or prepared in one State and transported into another, somewhat similar to the interstate-commerce act, with possibly the advantage of the power to enforce its rulings when once rulings were made. But with the little progress that was made there, and especially when we found that in consequence of the pressure of work in Congress none of the bills were likely to go through, it occurred to us that perhaps a pure-food commission bill might be passed, and an effort was made in that direct on. For a time, to the outside world at least, it seemed as though that might be practicable. But as it got closer to the end of the session we found that that could not be accomplished, and Senator Mason, as you know, then asked that a subcommittee of the Committee on Manufactures be empowered to sit during the interval between the last Congress and the present one and take testimony in regard to it. So that, having passed into the hands of the State in our own State, and progress seeming to have been made in efforts toward Federal legislation, we concluded that we had done as much as we could do actively, giving our time, efforts, and our own money to the advancement of this, and that we had better wait and see the outcome, so far as the action of Congress was concerned, and, so far as it would be practical for us to do so, to cooperate with our State authorities to secure this pure food. We have not especially advocated any of the bills that have been introduced into Congress. When the matter was up for a pure-food commission—trying to get a pure-food commission—we sent a memorial somewhat of this character to Congress. (Reading:)

"The National Pure-food Association was incorporated in 1897 under the laws of the State of Illinois for the purpose of investigating the subject of food, its production, manufacture, commerce, and preparation, and to disseminate among the people the knowledge thus gained for their benefit. In the belief that this matter would commend itself to the National Government and receive its support, an effort has been made, and it is being made, to properly present the aims of the association to Congress, asking such legislation as may seem best suited to give the movement national character and national support for the good of the people. The highest aim is to secure health and well-being for mankind, with just reward to the producer and economy to the consumer.

"To secure these important results, in view of the present almost unlimited sophistication of food, the National Pure-food Association asks that Senate bill 5375, introduced by Senator Thurston, to create a pure-food commission, be enacted into a law, and it does so in the belief that such a commission would prove to be a practical and an efficient means of securing such facts relating to food for man as are important if not indispensable to a proper understanding of the existing situation as a basis for such legislative enactments, national and State, as may be necessary to remedy existing evils as they relate to the food supply for mankind, and thus to better guard the public health in the future in the interest of the individual and of the Commonwealth."

Then there are some extracts from the resolutions passed by the Domestic Science Association of the Farmers' Congress, and so on. I will leave some of these with you, showing the direction in which we were trying to work.

Q. (By Mr. CLARKE.) If you wish to make them a part of your testimony, I would suggest that you mark those passages, making the selections as brief as you can.—A. They are reprints and I will just leave them—reprints stating what the resolutions were, and so on.

As I stated to Mr. Harris, a chemist was employed by the proprietor of a restaurant in this city, who brought a pie to him one day and said, "I want an analysis made of this, we are selling our pies as cheaply as we can to make a profit; our competitor is underselling us; and I want to know what his filling is that he is putting in, that he can undersell us as he is doing." The man made an analysis and he said the result was of such a character that it led him to buy some articles himself from the same restaurant and analyze those. After he had done that in half a dozen instances he said, "I came to the conclusion that I would bring my lunch down with me. I had taken all the down-town lunches I wanted." And he went on to specify what his experience was, and it was such that I wish he could have been present this evening to relate it to you.

In some of our addresses to the public we have taken up the effect of this upon the human system. Taking man as a human machine, and his productive power, what is the effect primarily upon the individual? As we have seen, if the food is deficient in nutrition, it impairs health, it impairs comfort, it impairs the working capacity of the man as an individual member of the community, and so in that way depreciates his value to his employer. It militates against the interests of the employer and his manufacture or industry or whatever it may be. Take one individual and notice the difference in the productive results of that one

man. Multiply that, as it must be multiplied, many times with many of our large manufacturing establishments. I had occasion to appear before representatives of one of our largest industries in the city a few years ago, employing some couple of thousand of men. I was advocating improvements in the interest of the masses of the people and was in position to give them assistance. To illustrate the subject, you take one man whose health is impaired, who feels that he must go to his work in the morning or he will lose that. He is not capable of doing justice to himself or to his employer. Multiply that as many times as you have to multiply it with the large number of men in your employ, and what is the difference in the productive results to you? That is a question of dollars and cents. On the other hand, what is the effect upon the man and his family? It is not the man that is well fed, well nourished, in good health, comfortably housed, that depends upon artificial stimulants. It is the man that is depressed mentally and physically who wants something that will brace him up, as he expresses it; and as he braces himself, it is like using kindling wood to get up a quick fire. It burns rapidly and burns out quickly. He wants to prevent freezing and he wants to get warmed up, and that is just the way with these men. They are the men that patronize our large number of saloons in this city. The walking delegate will get that man's ear when the temperance missionary will not. The delegate will tell him that his employer is rolling in wealth that he can not spend while the employee is not getting money enough to purchase the food that is necessary to nourish him, and his family is suffering also. He believes that he is a very much abused man. So I tell them that it is a much more efficient temperance work to have that man's body well nourished than it is to send a temperance missionary to him.

Now, take the effect upon the dealer, the man that is selling this diluted food—we will call it sophisticated food, or whatever term you see fit to apply. He may do it against his inclination. He says, "My competitors are doing it and underselling me—that is, by putting in the filling—and we have to meet that competition." He quiets his conscience; it becomes a matter of necessity with him to meet them on their own grounds or to go out of business. Therefore it is demoralizing to the individual himself. It impairs confidence in his business integrity as an individual. When that is multiplied through a large number of individuals it impairs confidence in business integrity at home and abroad. It militates against productive interests, and in that way militates against the interests of the Commonwealth. It is far-reaching in its effect from a physical standpoint, from a moral standpoint, and from a financial standpoint, militating against the interests of the State and the nation.

The question then comes, Can anything be done to stop this practice that is now almost at flood tide? It is with the hope that we might be able to present something from our practical knowledge here in this city, which is regarded as one of the storm centers in this matter, that we have come before you, to see whether we could present it in such a way as to throw any new light from personal observation and experience and our efforts in this direction.

Another feature that I have marked is the question of uniform legislation by the various States—first, to endeavor as well as we can to secure uniformity in laws, and in the next place, in the interpretation of those laws, or, as it is expressed, the ruling. Since our pure-food law has gone into effect the rulings of our commission here have raised the question as to whether it is not going to drive out some of the industries from our State that are desirable. Such laws should be framed to be as definite as practicable, that it may be understood what was intended, and that that object may be properly carried out and not diverted by rulings of the officers. So that question within the last few days has come to my knowledge in regard to a business that has been here for some time and built up a very worthy industry that is likely to be driven from the State under the ruling of our commission. But what shall be equitable to the laborer and the employer and to the producer and the consumer? What I have just said in elaboration of the effect upon the individual as it relates to his employer reaches that industry and affects the credit of the city, the State, and the National Government so far as its results are concerned. As to the protest and the exclusion of many of these things from European markets, those that they adulterate and send over here of course they are not going to raise any objection to, but as it is a poor rule that does not work both ways. It is a question whether, while trying to protect our own industries and not injure those, we shall open the door to spurious importations from other countries. As has been shown here this evening, if they fail to find a market for them in one city they will find it in another more closely in touch with market conditions which concern their business and industry in the United States.

Q. (By Mr. A. L. HARRIS.) Is your association working in connection with the

food and dairy commissioners, as they are sometimes called, in the different States?—A. No; we have done nothing of the kind. Our work was more tentative, confined more particularly to our own city and our own State, hoping through some of the officers and others to bring it before other States and before the Federal Government.

Q. There is no necessary conflict, I suppose, between the work you are doing and the work they are doing along their line?—A. No; on the contrary, we are trying to profit by what they have done, and if they see anything to profit by what we have done they are free to do so. The nearest that we have come to that is to have some of our officers attend some of the farmers' congresses and the Domestic Science Association, and thus give the results of our effort to draw attention to the importance of the work and what we believe to be the practicability of going on in the evolution just as we have done in sanitary science. We are trying to cooperate with everybody without trying to antagonize anyone. We have the same object in view, only working through different channels for the same end.

Q. Have you sent representatives to the National Pure-food Congress?—A. We have done so. I myself did not appear because I had an impression that there were more personal—I will not say wholly selfish—motives lying back of a good deal of the work; and as president of the association I felt that it would be better if I kept aloof from anything that would be even open to question. It was thought desirable that we should have representatives there, and some of our directors were present at the congress. But we felt that we were on broader ground; we did not wish to antagonize and did not antagonize in any way; but we believed that as our association was free from personal bias, no personal ends to be accomplished by it, that we had better maintain that position.

Q. Does your association support the bill that was agreed upon by the recent pure-food congress at Washington?—A. We have not committed ourselves to any bill or proposition. We went so far as to ask for that bill to create a pure-food commission. We have not advocated anything else. We ask simply for the principle; we do not care how it originates, where it originates, or who originates it, simply that it shall meet the object that we have in view—to secure pure food for the masses of the people as the foundation for good health and efficient working force.

Pure food is the first demand of animals, the human animal as well as the inferior. It begins with the beginning of life and only ends with the ending of life; and yet here we are at the closing of the nineteenth century, and how much do we know of most of the food—the masses of the people? I speak of practical value for the nourishment of our own bodies—the nervous and muscular systems. We have gone on all this time and we are still groping in darkness, just as we did in regard to sanitary science up to a quarter of a century ago. With all man's boasted intelligence it is humiliating to us to think how little we know in regard to the character of food, its purity, the effect of different kinds of food upon the system, the methods of preparing it, the injurious effects of certain modes of preparations, being guided simply by our tastes, whether they be educated or perverted. But we do not care how that is gotten so long as we can reach the object that we have in view—of securing, first, good, pure, nutritious, and economical food; next, that the people may be instructed how to prepare and utilize that food to the best advantage from a physical standpoint, from an economic standpoint, from the mechanical force that is produced, considering man as a machine, where we put food in to develop the power instead of putting coal into a furnace to generate heat, steam, and electricity as another means of motive power.

I personally should be opposed to the advocacy of any bill having any selfish object. I think it is the right of people when they want to buy anything, to have the privilege of buying it, and I think it is the duty of the vendor to let the people know what they are getting and what they are paying for, and the law should secure this.

There is another illustration of dilution: A man from an adjoining State was telling me that a miller in his vicinity regulated the amount of dilution of corn meal by a man's promptness of pay, doubtful pay, or prospect of no pay at all. If he was prompt pay, he got corn meal; if he was doubtful pay, he got a certain percentage of corncob along with the corn, and if he was very doubtful he got a very large proportion of cob and comparatively little corn. That man had little opportunity of knowing how much he was being cheated. In many instances a farmer himself might be able to judge of it; others that were using it would know comparatively little of the character of the feed they were getting to feed to their animals. So that it was not only the power of the man that would be diminished, but of his animals that were to be fed upon that. My own impression has been that a man should be at liberty to buy what he wants, and

Dr. Wiley at Washington a great many investigations have been made into the adulterations of food. The records of the Department of Agriculture, division of chemistry, show facts similar to those which I have stated—that adulterations are not generally of a harmful character, but of a character which dilutes the food. I have with me a few samples of such food, which I collected while acting as chemist for the department of health of Chicago. [Witness produces samples.]

Here, for instance, is some ground coffee which contains dried grain. There is nothing injurious in the use of dried grain. In fact, there are now sold many compounds which are substituted for coffee which consist of dried and browned grain; but that was sold as coffee.

Here is a sample of artificial coffee beans. Here is a sample of ginger filler. It looks just like ginger, is not injurious to health, and is used to fill out and make a cheap ginger or to adulterate the ginger, for which they charge the same price as good ginger.

Q. (By Mr. A. L. HARRIS.) What per cent of good ginger is in that?—A. There is no ginger whatever in it.

Q. None whatever?—A. No; these are fillers. This is pepper filler. Here we have cinnamon fillers. I simply brought a few of these. Practically all the spices are imitated in this way. Here is a sample of supposedly cayenne pepper, which contains no pepper. This is nutmeg filler, this is mustard filler, this is allspice filler, and this is clove filler.

Q. Can you state what the filler is composed of?—A. The fillers are composed of dried and pulverized grains. It is stated, although I have never found it, that ground olive stones are used to imitate black pepper, and I know that ground buckwheat hulls are used to imitate black pepper, and are used as so-called filler. Of course, it is practically impossible to find where these fillers are made, but they are on the market and are extensively used. They are also extensively used for filling drugs. I can conceive of no more hollish crime than that of man who will first adulterate the food and break a person's health down by adulterated food, and then sell him an adulterated drug in the attempt to cure him; but that is done, and frequently done. As an example of an injurious adulteration, I might mention pease which are greened with copper. This bottle contains a little piece of platinum foil, upon which is plated copper from a can of French pease. In the process of analysis copper is obtained in that way by plating on a piece of platinum foil.

Q. (By Mr. KENNEDY.) Will you explain the manufacture of these coffee beans?—A. I can not. Those coffee beans I obtained from Dr. Wiley.

Mr. A. L. HARRIS. In appearance they look like genuine beans.

The WITNESS. The only way you can tell is by examining the crack in the bean. It has not that feathery substance found in the genuine. Here is another class of adulteration which is unintentional sometimes, and not classed as an adulteration; that is, the making of filthy foods, either in a careless manner or by people who assume a way of don't care. For example, there is a piece of bread with a young rat baked in it. There is a sample of candy. When I obtained it it was dusted over with flour. It was sold in a department store, and while it appeared to be perfectly good, on brushing away the flour it was found to be in an extremely filthy condition.

These are a few samples of adulterated food. Grocers and men who are selling foods become so used to handling things of that kind that they seem to forget entirely the position that they hold and what they owe to society. As I said before, it is merely a question of what they can get for the goods, and selling them with the hope that they will not hurt anybody. To illustrate this, they tell a story of a grocer who once called down to his boy and asked him if he had watered the oysters, and he said yes; and mixed the tea (?), yes; well, then, come up to prayers. I merely tell this to express the idea that they become so used to things of that kind that it becomes a second nature to a man to sell adulterated goods.

Now, as to the remedy for this kind of thing: We have a great deal of legislation in regard to pure foods, but every State has its own laws. The State of Michigan has excellent food laws. A spice dealer told me recently that they had to be very particular about the spices they sent to Michigan. Illinois has recently enacted a food law which is now in operation. Massachusetts has splendid food laws; also many of the other Eastern States; but until we have some national legislation which will cover the whole country we can do but little. If a man who has a poor class of goods in one State can ship them into another so that they pass, we can do but little. If they do not pass inspection in one State they are very apt to in another. The remedy for that thing would be to force manufacturers to mark goods for what they are. I personally do not object to the use of butterine. I consider it good food, but I do not want to buy it for butter and pay butter price for it; other foods in a similar manner. If a spice is filled and I wish to buy a pepper which is not

as pungent and as full strength as pepper I want to know if it is a filled pepper, whether it contains buckwheat hulls or ground peanut shucks. For instance, a package containing filler should be marked that it contains so many per cent of ground peanut shucks. Then people can take their chances on what they are buying. Nothing can be accomplished unless we have some national legislation in regard to the marking and tagging of goods.

Q. (By Mr. A. L. HARRIS.) Have you any bill in Congress in mind that would give the remedy that you propose?—A. I know of no bill at present in Congress, but I have great hopes that some law will be enacted in connection with the recent investigation of pure food—I believe it was under Senator Mason.

Q. I suppose you have examined what is known as the Brosius bill?—A. No; I have not.

Q. Would you establish a separate department, or would you place it under the control of the Department of Agriculture?—A. I would place it under the control of the Department of Agriculture; they have had more experience with it.

Q. Has Senator Mason introduced a bill along that line?—A. I have been looking for it, but I have not seen it.

Q. (By Mr. KENNEDY.) I should like to have you tell us something about the extent of the use of glucose in food and the effect of it on the system.—A. I place glucose in the same category as butterine. I do not consider glucose harmful. Many of our fruits contain glucose—grape sugar or glucose. It is a good food if properly used. There would seem to be a great prejudice against glucose, particularly a few years ago, because it seemed to hit the sugar business. There is nothing in glucose that is harmful.

Q. Is there anything of value in it as food?—A. Glucose is a valuable food; yes.

Q. (By Mr. CLARKE.) Have you had any experience, when serving the city government, with the difficulty of getting manufacturers of foods and dealers in foods to label them?—A. Yes. We have a law in Chicago requiring milk dealers to mark skimmed milk with a tag—a tin tag upon the can upon which is stamped the words "Skimmed milk."

Q. (By Mr. KENNEDY.) That is simply a city ordinance, is it not?—A. Yes. We experienced considerable difficulty in getting them to keep a tag on the can, but the ordinance has undoubtedly accomplished a great deal of good.

Q. (By Mr. CLARKE.) Do you know how milk is ordinarily adulterated?—A. The ordinary adulteration of milk is by removing the cream. This seems to exclude the right to the word adulteration; it properly comes under the head of sophistication, as it is called. The removal of the cream from the milk produces an unbalanced food. It takes away the larger part of the food from the milk, so the milk then is an unbalanced food. That is the principal way in which milk is adulterated in Chicago.

Q. What is done to restore the appearance of the milk somewhat to its ordinary state?—A. That is done by coloring.

Q. What is used for that coloring?—A. The color which is used in these days is annatto, and also aniline dyes. Annatto is very much used.

Q. Are aniline dyes and annatto harmless?—A. It is an unsettled question as to whether those dyes, a number of them, are harmful or not. Some chemists believe they are harmful, and others that they are not. It is hardly a settled question.

Q. Is it your opinion that there is very little pure milk sold in cities?—A. Yes.

Q. You spoke of the high character of the pure-food laws of Massachusetts. Have you any knowledge as to whether pure milk is obtainable in Boston and some other large cities there?—A. As far as my experience goes, Boston probably has the best milk in the country; in the East, at any rate. The milk is naturally of a high standard in Boston. In Boston, for a part of the year, the standard of total solids in milk is 13 per cent, whereas the standard of total solids of the milk in Illinois is 12 per cent. In Illinois the milk would not stand such a standard as 13 per cent.

Q. What would be the average standard of pure unadulterated milk?—A. Twelve per cent of total solids. The rest, of course, would be water; that would be 88 per cent natural water.

Q. Can you suggest any other law for securing unadulterated food than correctly labeling it?—A. I have given the matter a great deal of attention and I have given it a great deal of study and reading, and I know of no other way that the matter could be handled than by labeling and inspecting goods after they are labeled, in such a manner that the manufacturer may never know when his goods are likely to be taken and inspected.

Q. Is it your belief that there would be any market for adulterated foods if they were so marked?—A. There is a market for them; yes. There is a large market for butterine that is so marked, a very large market.

Q. Do you think there would be for pepper of the character of the sample that you have shown us here?—A. It would be doubtful.

Q. Coffee and ginger?—A. There is a market for adulterated coffee; but unfortunately that is among the restaurants, and the people who use the coffee never would know it. Such a law would prohibit the larger proportion of adulteration.

Q. (By Mr. A. L. HARRIS.) Could not a law be framed to prohibit the use of imitation coffee in a restaurant?—A. I should think it could; yes.

Q. (By Mr. CLARK.) In regard to washing powders—are you familiar with them?—A. Somewhat. Shall I mention any brands?

Q. You can or not, as you choose.—A. You mean similar to Gold Dust, Pearline, and such things as that?

Q. Yes; things of that sort; are they composed of anything that injures the fiber of goods, especially cotton goods?—A. The washing powders—I understand that the first that was put out was made up of a lot of soap which was not of good quality. This soap was ground and sold in a pulverized form as washing powder, and a large market was found for it. Then other manufacturers commenced the manufacture of washing powders. They are practically soaps. A number of them contain free alkali and have the same effect as adding sal soda to the water in which the washing is done. Fabrics which would be injured by the alkali are injured by the washing powder.

Q. Do you know, practically, how much the life of cotton garments is shortened by the use of these powders?—A. No.

Q. If you thought that the evil was general and that garments ordinarily will not wear more than one-half as long when these powders are used as when they are not, do you think it should be a subject of legislation to prohibit the use of such powders?—A. I never have given that subject much consideration. I should prefer to consider that before making an answer. It is not such a vital question as the question of the health of the people.

Q. It is rather more of an industrial question than the food question or health question, perhaps, but of course there can be no economic value to the people at large, especially to consumers, in having their garments destroyed before their natural time.—A. People can find out such things for themselves very easily, but in using such a large variety of foods they have no means of knowing what it is that is injuring them; whereas if a person is using a certain soap and finds that his clothing, which was washed with this soap, was rapidly deteriorating, he would naturally make some change.

Q. Supposing they were unable to make a change, finding that the use of these powders or soaps rendered washing easier, and therefore their domestics would use them on the sly, you would not know how to grapple with that problem?—A. It is rather a difficult problem to grapple with—the domestic problem.

Q. (By Mr. KENNEDY.) A great many people drink beer, and I presume you will agree that if they will drink beer it would be to the advantage of health that they should drink pure beer?—A. Certainly.

Q. I would like to know whether you have ever had occasion to make analyses of beer, and if you can tell us something about the impurities of beer?—A. I have made a number of analyses of beer, but I never have found anything particularly injurious in beer, although I have been told and frequently read of adulterations of beer which are undoubtedly injurious. Some of the foreign beers have been colored with picric acid.

Q. Colored after they come here or before?—A. No; colored abroad. There is a great deal of beer made with impure water, which would come under the head of an adulteration.

Q. Have you learned that in your investigations?—A. Yes.

Q. (By Mr. A. L. HARRIS.) Have you any law in Illinois called the bakery inspection law?—A. I do not know of a bakery inspection law in Illinois.

Q. No law requiring bakeries to be above ground?—A. If there is such a law, I do not know it.

Q. Has there been any adulteration of flour with anything such as flourine since the Federal legislation on that subject?—A. You mean the adulteration with corn flour?

Q. With corn flour; yes.—A. Whether any adulteration with corn flour has been done in this city, I do not know. I know that a friend of mine, who is a chemist, has examined a great many samples of flour without finding corn flour. I have made no investigation of it myself.

Q. Would flourine be deleterious to health?—A. By flourine you mean corn flour?

Q. Yes.—A. No; it would not.

Q. But it would be an adulteration?—A. It would be an adulteration; yes.

Q. And there should be a law to prevent the adulteration so that the consumer could buy what— A. (Interrupting.) Buy what he pays for; what he asks for.

Q. Did you make any analyses of molasses during the time you were a chemist for the city?—A. A few, yes; not more than four or five.

Q. What was the result?—A. I found nothing deleterious in molasses.

Q. Molasses labeled "pure maple molasses?"—A. Yes. I examined some maple molasses and was unable to tell whether cane sugar had been added to it or not, because cane sugar is a natural constituent of maple molasses.

Q. In the absence of national law, what would you recommend to the State in regard to the protection of the purchaser against impurities in food; would you hold the seller liable and make him liable under the law, or would you try to trace it to the wholesale dealer or the manufacturer?—A. I see no reason why the seller and the manufacturer should not both be held.

Q. These samples that you have exhibited to-night, are they all of the adulterations that you found in your experience as a chemist for the city?—A. Oh, by no means, no; these are only a few samples.

Q. You may state in a general way how much adulteration you found during your official term?—A. I found that there were very few foods which are not at times adulterated. There seemed to be adulterations for practically everything. For instance, cream of tartar is sold in Chicago, a so-called cream of tartar, which contains no cream of tartar whatsoever, but consists of soda calcium phosphate, which is similar to the phosphate rock which is sold as a fertilizer. There is nothing unclean about it. And I have analyzed samples of cream of tartar which contained as high as 55 per cent of plaster of paris. Whether it was added as plaster of paris or came in in the manufacture of this soda calcium phosphate, of course, I am unable to tell.

Q. What effect does plaster of paris have upon the stomach?—A. Well, it is simply so much inert matter; it can not be digested; it is equivalent to eating so much sand.

Q. You may state any other impurities that you discovered during the time, that you now call to mind, and what the impurity consisted of, or the adulteration?—A. I found practically all spices adulterated at times. I know of the adulteration of flour with corn flour, of butterine sold as butter, of olive oil adulterated with cotton-seed oil, and many other adulterations that I do not call to mind right at present.

Q. (By Mr. CLARKE.) I wish to inquire if olive oil is not actually improved for consumption by a proper admixture of cotton-seed oil?—A. Do you mean more palatable?

Q. Yes.—A. I have used cotton-seed oil, knowing that it was cotton-seed oil, as a salad oil, and I like it just as well as the olive.

Q. Are you not aware that large quantities of cotton-seed oil are shipped from this country to Italy and Spain and mixed with olive oil to the improvement of that oil for that market?—A. I do not know that it is to the improvement of it, but I have been informed a number of times that cotton-seed oil was shipped to Europe and repacked and sent back as olive oil. As far as its food value is concerned, I should consider the cotton-seed oil just as good food as olive oil, or very nearly so.

Q. You would not deem it necessary, then, to provide by law against an admixture of that character, which really does no harm, would you?—A. Yes. I do not believe in allowing anything to be sold for what it is not. Who is going to decide whether it is just as good as olive oil? Would not that open the gate to allow all sorts of things to be handled in that manner?

Q. Would you extend similar legislation to the matter of fabrics? Take woollens, for instance; would you require that woollen garments should be labeled as to the per cent of pure wool used in them—such a per cent of wool extracts and such other per cent of shoddy?—A. I have never given that matter consideration.

Q. You can see how it might affect the health, as well as the wearing qualities of the garment, can you not?—A. Yes, I can.

Q. (By Mr. A. L. HARRIS.) In the composition of a cheaper product for a pure product what effect does that have upon the production of the pure product, or rather the encouragement of the production of the pure product?—A. Of course if we allow a poor product to be sold as a good product it keeps down the production of the good product, because the poor product can be sold for a lower price; there is more market for it. Therefore, the good product does not have so great a sale and there is not such an incentive to produce it.

Q. What would be the effect eventually, then, without some legislation to protect it?—A. The effect eventually would be that good products would be driven out of the market entirely. When manufacturers find that there is not a sale for the good product, they must make a living, and they will naturally go into the manufacture of the poor product.

(By Mr. CLARKE.) Do you think of any further statement.

that you would like to make?—A. No.

(Testimony closed.)

CHICAGO, ILL., March 27, 1900.

TESTIMONY OF MR. F. M. M'KAY,*Trustee of the University of Illinois.*

The subcommission met at 7.15 p. m., Mr. Clarke presiding. At 9.25 Mr. F. M. McKay, of Chicago, a trustee of the University of Illinois, was introduced as a witness, and, being duly sworn, testified as follows:

Q. (By Mr. CLARKE.) Please give your name, post-office address, and occupation.—A. F. M. McKay; Chicago, Ill.; 61 Alice court; public-school teacher; trustee of the University of Illinois.

Q. (By Mr. A. L. HARRIS.) Are you interested in the domestic science question?—A. Yes; I think that all American citizens ought to be interested in that question.

Q. You may state in your own way such information as you think would be of use to the commission.—A. I think that there ought to be national legislation along these lines for securing pure food for the consumer. That ought to be under the control of the Department of Agriculture of the National Government. State laws are too desultory and conflicting to be very effective or to secure the best results. Inasmuch as the National Government has established these experiment stations in very nearly all, if not all, the States, it seems to me that through these experiment stations they can obtain the necessary information in regard to the food supplies of the various States, and therefore the Department of Agriculture is the proper body, it seems to me, to originate the most effective legislation. I would suggest that a special appropriation be made by the National Government to each one of these experiment stations for carrying on investigations upon this specific subject of pure food.

In regard to the land-grant colleges organized by act of Congress in 1862, that law provided that these institutions' main object should be instruction in agriculture and mechanical arts without excluding other scientific and classical studies. This left an opportunity for the States to organize under that law not merely agricultural and mechanical colleges but universities of the broadest type, of which Cornell University is, perhaps, the best example in this country; and the gentleman for whom that institution was named said his desire was to organize such a university that any person could obtain the best instruction in any branch of human knowledge. Many of these universities have developed into real universities. Congress wisely, I think, left the courses of studies to be prescribed by the various States through their boards of trustees, giving each institution an opportunity to develop along lines that seemed to be demanded in the various communities where these institutions were established. It has been the aim of boards of trustees to meet the demands for instruction in various branches in the communities where their institutions were established, and I believe that these institutions have very largely met the demands for instruction in various branches of human knowledge. If there was a large demand for instruction in mechanical engineering, it will be found that the college of mechanical engineering has developed very rapidly; if there was a large demand for electrical engineering, it has happened that large sums of money have been put into the equipment of the electrical engineering department. If there seemed to be little demand for any specific branch of instruction there was not very much money put into that department. When these institutions were established, back in the sixties, there was not much demand for a scientific instruction in agriculture, especially in these Western States. If a man could go on to the prairies of Illinois and by turning over the soil and cultivating it very indifferently raise a crop of 50 or 60 bushels of corn to the acre, he could not see the necessity of studying the value of fertilizers or going into the analysis of soils and then selling his corn at 10 or 15 cents a bushel, because it did not pay. The time has arrived when it is necessary, to make farming successful, that each acre of land must produce the best possible results. There is now arising a demand for scientific agriculture, and I believe that these institutions are going to meet that demand. It is certainly the intention in Illinois to do that, as the board of trustees has asked for large appropriations for the college of agriculture. I think I may say that when our building now in process of erection is completed we will have the most complete equipment there is in this country. I think that is all I care to say unless there are some questions.

Q. Does the university overshadow the agricultural and mechanical departments of these colleges?—A. No. The literary department is overshadowed altogether, and always has been, in the University of Illinois.

Q. What is the tendency of the farm boy, when he comes to the university and studies the classics in connection with agriculture, to go back to the farm?—A. If you refer to the classics there, as to Latin and Greek, I will say that there are very few students in the University of Illinois studying Latin and Greek, and there has never been any considerable number studying those languages. If you refer to the literary college or the college of literature and arts, including English and the modern languages, such as French and German, I will say that that college has always had a larger number of students, I think, than any of the other colleges. As we are organized there, we have four colleges: The college of agriculture, the college of science, the college of engineering, and the college of arts. Recently we have organized the college of law and the college of medicine; I had almost forgotten those.

Q. Is there any complaint on the part of agriculturists that their sons, after graduating even in the agricultural course at a university, do not come back to the farm?—A. I think I have heard such complaints; yes.

Q. Do you know the per cent of those?—A. No; I could not state the per cent. Q. Do you believe it to be large or small?—A. I should say of those that took an agricultural course, that the per cent who went back to farming was very small, and I think I can state the reason for it. A young man going through the university in a 4-years' course has obtained a fairly liberal education. If he took the regular course in agriculture, he got more than simply the technical agricultural subjects. He had considerable literature, both English and modern languages, and he had a good knowledge of chemistry, physics, and biology. A number of these men are now deans of colleges of agriculture or professors of agriculture; some are directors of these experiment stations. I am speaking of our own graduates, now, from the University of Illinois. They went into these positions because they could earn more than they could on the farm. It was a matter of dollars and cents.

(Testimony closed.)

WASHINGTON, D. C., May 15, 1900.

TESTIMONY OF PROF. ROBERT C. KEDZIE,

Professor of Chemistry, Michigan Agricultural College, and Chemist of the Michigan Experiment Station.

The commission met at 10.35 a. m., Mr. A. L. Harris presiding. At that time Mr. Robert C. Kedzie was introduced as a witness, and, being first duly sworn, testified as follows concerning the beet-sugar industry:

Q. (By Mr. CONGER.) You may state your name and post-office address.—A. Robert C. Kedzie, State Agricultural College, Michigan.

Q. And your occupation?—A. Professor of chemistry at the State Agricultural College, and chemist of the experiment station.

Q. How long have you been engaged there?—A. Since 1863; 37 years.

Q. You may now, if you will, in your own way, give to the commission such information on this subject as you think will be of use and interest.—A. Before entering upon this, I have some specimens here that could hardly be taken down in shorthand, though sometimes done in spoon hand—specimens of the beet sugar itself as produced in Michigan, and a refined beet sugar from Germany; specimens of the beet sugar that is produced in Nebraska at the Grand Island Works, and then some mounted specimens of the sugar—a "study in sugar," as I call it—mounted specimens that give samples of the sugar produced from sorghum in Michigan and sugar produced from sorghum in Illinois. These specimens were prepared for the information of the members of our legislature, mounted in this form for comparison, when they had under consideration the question of offering a bounty for the production of the sugar beet—to encourage the introduction of the sugar-beet industry in Michigan. This is preliminary, and sometimes an object lesson of this kind assists in the understanding of the question more than the spoken statement.

I have written out here to a pretty full extent the remarks I have to make, and have commenced by saying that (reading)—

"The hope for a domestic supply for our people has been cherished in Michigan for years. In 1881 the legislature passed 'An act to encourage the manufacture of sugar,' exempting from taxation for 5 years the apparatus used in making sugar, and offering a bounty of \$3 for every 100 pounds of sugar. Under this

law 10 tons of sugar were made from sorghum and \$404 paid as bounty. It was found that sorghum as grown in our State was not profitable for making sugar, because the proportion of glucose to sucrose was too large to permit profitable manufacture of crystallized sugar."

Q. (By Mr. CLARKE.) Would you pause right there and explain for my benefit, on account of my ignorance, the exact difference between sucrose and glucose?—A. The chemical difference is that there is a little more water in the glucose. The proportions which make up the glucose are 6 equivalents of carbon, 12 equivalents of hydrogen, and 6 equivalents of oxygen; in the sucrose, or cane sugar, we have 12 equivalents of carbon, 23 of hydrogen, and 11 of oxygen. That is, if you will double the equivalent of the glucose and subtract 1 molecule of water, you have the composition of the sucrose. The difference, however, is more than simply the difference of chemical composition. The glucose is very difficult of crystallization in pure, well-defined, sharp crystals like we have here. It is a sweet material, but only about two-fifths the sweetness of the sucrose. But the difficulty, so far as the manufacture is concerned, is that when you have an equivalent of glucose present it will render uncrystallizable another equivalent of the sucrose, so that while the sorghum (Chinese cane) may contain a large amount of sugar—that is, sweetness—you can get from it only a relatively small amount of sugar in the form of clean, well-defined crystals. (Continuing to read.)

"Attention was then turned to sugar beets as a more promising material. In 1890 the college imported 200 kilograms of seeds of each of 4 kinds of sugar beets cultivated in Europe, viz: Klein Wanzlebener, Austrian Wohanka, Vilmorin Imperial Improved, and White Silesian. That was about 1,700 pounds, 800 kilos—200 of each. These seeds were given to farmers with directions for planting, cultivating, and harvesting the beets, requesting a sample for analysis. The seed was sent to leading farmers in all parts of the lower peninsula. Four hundred farmers received the beet seed and 228 reported results and sent beets for analysis. These reports came from 39 counties. The average content of sugar in the juice was 14.20 per cent, the coefficient of purity was above 80 degrees in 200 specimens and below 80 in 27."

This coefficient of purity—I might say a word in regard to that. We take the sugar beet and pulp it and extract the juice, all we can get; then by taking the specific gravity we determine the total percentage of the solids in solution—that is, materials that would be solids but for the water—the matters that are in solution in the water. Suppose we find that the total quantity of the solids in solution in the beet juice is 20 per cent, and then by other analyses we find that the proportion of pure sugar is 16 per cent. That would be 16 parts out of 20 pure sugar, and the other 4 parts would be nonsaccharin materials. That would give us a purity of 80 per cent. The purity means the proportion of readily crystallizable cane sugar present in the juice as compared with the total amount of solids there present. (Continuing to read:)

"The yield of beets per acre (estimated) was 13 tons. The season of 1891 was favorable for the growth of sugar beets; the average temperature from June to September was 64.55° F., and the rainfall 11 inches. September and October were dry and sunny, well suited to ripening the crop.

"Having thus demonstrated the adaptedness of Michigan to produce sugar beets of high quality and well suited to making sugar, the college did not further push these investigations. The agricultural problem was solved, but capitalists and manufacturers were not ready to enter and possess this land of promise."

"In 1897 general interest was awakened in this subject and legislation was secured to promote the manufacture of beet sugar. The lively interest taken in this subject by Secretary Wilson, and the aid from the Department of Agriculture in furnishing beet seed, transportation by mail, ect., greatly promoted the efforts of the college. Seed was sent to many leading farmers who would undertake to raise at least 1 acre of beets, also to a still larger number of persons whose work was of the amateur class. The season was only a fair one for sugar beets, the temperature for May and June being 3° F. below the normal, and the rainfall in July being 5 inches above normal, making cultivation difficult; but August and September were warm and full of sunshine, and October was nearly 5° F. warmer than normal. The beet crop was quite satisfactory. Specimens of beets received for analysis numbered 493 and came from 64 counties. The average content of sugar in the juice was 16.08 per cent, and the coefficient of purity was 80° and above (some went as high as 92° of purity), while in 85 samples the purity was below 80°, ranging from 62° to 79°. In most of these cases of low purity the beets were grown on mucky soil."

That has been a great difficulty with us. The farmers think they can raise beets, and they do raise mangels on mucky soil, and they think that is the soil for the production of sugar beets. It is for beets, but not for sugar.

during the growing season—the most severe for 36 years, from 1864 to 1900—even worse than that of 1871, the year Chicago was burned. The rainfall for the three summer months was 3.96 inches, while the normal rainfall is 9.50 inches. If we add to this the rain for September, 1899, the total is 6.10 inches, while the normal is 12.24 inches. The rain for 1871 for these four months was 8.24 inches, or two inches more than in 1899.

"In localities where the drought was very severe the smallness of the yield from this new crop from which so much had been expected was very discouraging to the farmers, and in some of their meetings resolutions were passed not to plant sugar beets. Other crops had suffered even more severely, notably wheat; but in the case of so well-known a crop as wheat the loss might be charged to an inscrutable Providence. Some of them seem to feel that while the old charter of agriculture given to Noah, 'While the earth remaineth, seedtime and harvest shall not cease,' will hold good for wheat, which has been so long and so favorably known, it can not be relied on for a new crop like sugar beets. Surely a careful study of the nature and habits of a new crop and its adaptedness to our soil and climate, and to the usual methods of farming in our State, is a wise precaution.

"Let me call your attention to the physical basis of sugar-beet raising in our State.

"The physical basis for growing a beet crop is the quality and the composition of the soil. In the lower peninsula the soil is technically known as the drift. The intermingling of many kinds of soil and the porous character of the deposit fit the soil for crops of the tuberous class in particular. The lands adjacent to the Great Lakes and the southern half of the peninsula are adapted to the raising of all crops and fruits suited to our climate, and especially tubers.

"Many years ago an invitation was extended to leading farmers in different counties of Michigan to send specimens of soil for analysis, which would fairly represent the leading agricultural soils of the county. It is probable that the best was sent that the county affords. This is human weakness run into the ground.

"Twenty-eight soils taken from counties that fairly represent the sugar-beet district are here selected to show the chemical composition as specially related to the demands of this crop, giving the average percentage of lime, potash, and phosphoric acid and the physical condition which enables the soil to take up and hold water by capillary attraction, and thus withstand drought, or water-capacity of the soil.

"Average of the most important ash materials:

	Per cent.
Lime (CaO)	1.13
Potash (K ₂ O)	1.36
Phosphoric acid (P ₂ O ₅)33

"This table shows the Michigan soils rich in the ash materials required for sugar beets. Potash is in special demand for this crop, and these soils are remarkably rich in this chemical.

"The relation of the capacity of soils to hold water by capillarity to their power to produce crops is coming into prominence as the result of recent investigations.

"Prof. Milton Whitney, of the Department of Agriculture, is making extended inquiries of this relation of soil and water in securing the best conditions for the production of special crops. The quantity of water which dry soils will thus take up or hold varies with the kind and texture of the soil. If 100 grams of quartz sand are poured into a funnel with a small filter to prevent the soil running out and water poured on the sand till completely wet, and the excess of water allowed to escape, it will be found that the sand will take up and hold, by capillary attraction, 25 grams of water or 25 per cent of its weight, which is its water capacity. If other soils are treated in the same way, they will take up a different percentage of water. A prairie soil, on the average, took up 62 per cent of water; fine soils from river bottoms, such as the Tittabawassee, or the river Raisin, 57 per cent.

"The less water a soil will absorb the more rapidly it will part with it by evaporation and by filtration. A soil whose water capacity is less than 32 per cent is liable to suffer in dry weather. The average water capacity of these 28 soils is 47.4 per cent, and shows the ability of our soils to withstand drought. The influence of the Great Lakes that surround us on every side except the south will attract the attention of everyone who glances at the map. Our winds receive a moistening and ameliorating touch in passing over these vast 'unsalted seas.' Not in vain has nature thrown her protecting arm around our peninsula.

"An adequate and distributed supply of water is an essential condition in agriculture. The average rainfall in central Michigan, as shown by 36 years' observation at the agricultural college, is 32 inches. Along the shores of the Great Lakes the rainfall is a little larger.

Average monthly rainfall during 36 years for the 6 growing months at the agricultural college.

	Inches.
May	3.23
June	3.50
July	3.23
August	2.77
September	2.72
October	2.44

"This shows on the average an abundant rainfall for May, June, and July, the period when the sugar beet requires plenty of soil moisture, when it is grappling with the soil and sending down the tap root to give it a hold upon the subsoil and derive its supply of food, both liquid and solid, from the deeper soil without absolute dependence upon the surface soil. In August there is an abrupt drop in the amount of rain, and a progressive fall in September and October. This is the season of our 'summer dry spell,' often becoming a veritable drought. This is the season of little cloudiness and abundant sunshine, when the beet is rapidly growing and packing its cells with sugar. If May, June, and the first half of July are warm and moist to establish and strengthen the growing plant, and if the balance of summer is hot and dry (short of drought) we have the ideal season for growing sugar beets. Sugar is essentially condensed air, water, and sunshine. With cloudy and rainy weather during these critical ripening months we would secure large beets and little sugar."

Now, in consequence of some remarks made by Dr. Wiley here yesterday in regard to the sugar beet as an exhausting crop, I have written a little digression that I would interpolate here. [Continuing to read.]

"The sugar beet is an exhausting crop when the whole crop is permanently removed from the land, because it takes off a large amount of potash and phosphoric acid and much organic nitrogen; but none of these materials are removed in the commercial product—sugar—which contains only carbon, oxygen, and hydrogen, a pure carbo-hydrate, the carbon coming from the carbonic acid of the air and the oxygen and hydrogen from the rain, all these combined and organized under the force of the sun's rays acting through plant life to produce sugar; not a particle of potash, phosphoric acid, or organic nitrogen being found in pure sugar. The sugar is essentially condensed or organized wind, water, and sunshine. No amount of sugar removed from the soil can reduce its crop-producing quality. Dr. Wiley charged me to say to you that 'the export of sugar can not impoverish the soil.'

"How, then, can sugar beets be an impoverishing crop? It is because of the removal from the land of other materials in the crop aside from sugar, substances which contain all the fertilizing substances which are found entirely in the leaves, crown, pulp, and molasses of no further use in making sugar. These by-products contain all the fertilizing materials of the crop, the removal of which is the only impoverishing element of beet growing. If these are all returned to the soil, either directly or by feeding to stock and returning the manure to the land, there is absolutely no reduction of the power of the soil to produce crops; on the contrary, an increase of fertility year by year. This is probably the reason why France has increased its wheat acreage from 17 to 28 bushels since the introduction of the sugar-beet industry. In Germany the farmers are not allowed to remove the leaves and crowns of the beet from the field. In both countries the sugar beet is considered the best possible crop to precede a crop of wheat. Another reason for the excellence of sugar beets as a preparatory crop is the kind of cultivation required for sugar beets—thorough and clean tillage, not only subduing the soil but keeping out the weeds—the tramps and bums of agriculture.

"It is only by retaining all the waste products of the sugar-beet factory and keeping them on the farm that the soil can be kept up in fertility and actually made more productive. The leaves and crowns of the beet should never leave the farm; the pulp should be converted into beef or milk by feeding to stock, or by drying the pulp, as proposed at Bay City, preparing it for long storage or transportation to a distance. Even the residual molasses should be fed to stock and not allowed to flow into the Saginaw River."

Q. (By Mr. CONGER.) Dr. Wiley stated that this crop could or should be raised only once in 4 years; what is your idea about that?—A. I think he is right in that. It should not be grown in succession, because any crop that is grown in continuous succession, unless it is weeds, is an exhausting crop, and weeds are the most exhausting of all.

Q. Is it more injurious to the land to raise beets in successive crops than it is to raise wheat so?—A. Yes, because the beets have a wider range for feeding, and the sugar-beet crop removes more of these elements from the soil than does the wheat crop. The wheat is called an impoverishing crop because it is a surface

feeder; the supply has got to be right at the surface, and while wheat is exhausting on the surface soil the sugar-beet crop is on the whole more exhausting for the soil as a whole, both the surface and beneath. It has been found, as a matter of wide experience in France and Germany, that the alternation and rotation of crops very thoroughly carried out is essential for the raising of beets.

Q. You speak of wheat as being a good crop to follow the raising of beets; what other crops would you recommend for the other 2 years, if beets are to be recommended only once in 4 years?—A. I would want to get in a crop of clover, the great catcher of organic nitrogen and atmospheric nitrogen, thus securing a supply of nitrogen for succeeding crops. The inversion of the whole crop is not so essential in the case of grain and potatoes, because the very thorough cultivation that must be had in regard to the beets to keep the weeds entirely out and keep the soil in the very best possible condition for the growth of the crop will assure a good condition of tillage for the succeeding crop. The land is in the best possible condition.

Q. If wheat is to follow the beet crop, what should precede the beet?—A. A barley crop frequently precedes it; some sown crop; what in England they call white crops; that is, some grain crop.

Q. (By Mr. A. L. HARRIS.) Can commercial fertilizer be used to advantage?—A. Unquestionably; but the point I wanted to make was simply in offsetting the, as I thought, a little too strong statement of Dr. Wiley, that it was the absolutely exhausting crop of all crops. It is absolutely the exhausting crop only as it is the crop which is mismanaged so far as the by-products are concerned. Now, you take, for instance, in the case of the growth of crops in China, where, according to the Chinese tradition—which may not be the most reliable—but still it is supposed that their soils have been in continuous cultivation for over 4,000 years, and they are still rich and productive. It is because they return everything to the soil. The excrement of every kind of animal, and human excrement, are saved as you would save gold, to go back on this land, and the consequence of it is the soil has not fallen off in productiveness, but has continued to produce for all time. Where we export the wheat crop we are carrying off our fertility. Sir Humphrey Davy, in his earliest lectures on agricultural chemistry, stated that the continuous production of corn—that is the English term for grain—that the continuous production and exportation of corn leads inevitably to the destruction of the fertility of the country, and instances Sicily as a country which has been thus denuded.

Now, in the case of sugar beets nothing of this kind takes place, because all that is taken off is wind, water, and sunshine, and we can have that in abundant supply. There is no necessity nor call for the impoverishment of the soil so far as the production of commercial sugar is concerned, because it contains no elements of fertility whatever.

After this digression I return to the subject of rainfall, so far as fertility is concerned. [Continuing to read.]

"The distribution of rain during the growing months is a matter of importance. If we assume 2 inches of rain per month as the minimum for most crops we find that during a period of 36 years in central Michigan the months of May and June have each had less than 2 inches of rain for 5 times; July, 11 times; August and October, 14 times, and September, 14 times. If the crop is not a surface feeder, like the grains, but a deep feeder, such as the tap-root plants, even less than 2 inches will suffice for a time. But if the plant is a sunshine feeder the absence of moist weather is a matter of less consequence during late summer and early autumn.

"It must be conceded that by reason of soil, climate, and peninsular position Michigan is well adapted to production of beets for making sugar. Another important condition is the intelligence and energy of our people. Some Europeans are horrified at the presumption of our people in assuming that, without decade after decade of training and drill, our people have the audacity to suppose they can make sugar from beets. What might be called presumption in others may be enterprise with us. After putting their hand to the plow our people are not inclined to look back. One evidence of the tendency to press forward is the bounty law of 1897."

I have introduced here the whole of this bounty law because it is a matter of history. It is an act which was passed in 1897, approved on the 26th of March, 1897. Summarized, it provides for the offering of a bounty of 1 cent a pound for all sugar produced above a certain degree of purity; and for the securing of the data concerning the amount of beets so raised, and requiring a certain amount of payment by the ton of 2,000 pounds for all beets raised, guarding against frauds on the Government and so on. This was the bounty law of 1897 and gave us the great start in regard to our sugar-beet industry, so far as the manufacturing was concerned. (The law above referred to is as follows:)

THE MICHIGAN SUGAR-BEET BOUNTY LAW OF 1897.

[As part of the history of the sugar beet in Michigan.]

[No. 48.]

AN ACT to provide for the encouragement of the manufacture of beet sugar and to provide a compensation therefor and to make an appropriation therefor.

SECTION 1. *The people of the State of Michigan enact, That there shall be paid out of the State treasury to any person, firm, or corporation engaged in the manufacture in the State of Michigan of sugar from sugar beets grown in the State of Michigan one cent per pound upon each and every pound of sugar so manufactured under the conditions and restrictions hereinafter provided.*

SEC. 2. No money shall be paid for sugar so manufactured unless such sugar shall have been so manufactured in this State and from beets grown in the State of Michigan, and unless such sugar shall contain at least ninety per cent crystallized sugar, and the manufacturer shall produce good and sufficient receipts and vouchers to show that at least four dollars per ton of twenty hundred pounds has actually been paid for all beets purchased containing twelve per cent of sugar, said twelve per cent being the basis for valuation of the purchase price of four dollars per ton. The quantity and quality of sugar upon which all of said bounty is claimed shall be determined by the commissioner of the State land office, with whom all claimants shall from time to time file verified statements showing the quantity and quality of sugar so manufactured by them, the price paid the producer for the beets actually produced in this State, upon which said bounty is claimed.

SEC. 3. The persons, firms, or corporations so intending to engage in the manufacture of beet sugar in this State shall, before commencing the same, file a statement with the commissioner of the State land office setting forth their proposed undertaking, the capacity of their manufactory, the number of tons of beets they intend to manufacture per annum, and request said commissioner of the State land office to appoint a suitable weighman and inspector, as hereinafter provided.

SEC. 4. It shall be the duty of the commissioner of the State land office to appoint a resident weighman and inspector and such assistants as may be necessary in each town where it shall appear to him from the application of the persons, firms, or corporations so engaged or intending to engage in the manufacture of beet sugar, that such weighman and inspector is needed, and in all cases where the output of persons, firms, and corporations engaged in the manufacture of beet sugar in this State shall aggregate or exceed two thousand pounds per day, and such weighman and inspector shall weigh all beets received by such persons, firms, or corporations engaged in the manufacture of beet sugar, and keep an accurate account of the same with each and every purchaser of sugar beets and make such examination and test as to the quantity and quality of the sugar so manufactured as he may deem proper in arriving at the standard of sugar in each town so manufactured by such persons, firms, or corporations. The sugar thus manufactured shall, under the direction of said weighman and inspector, be placed in original packages, which shall be examined, weighed, and branded by him by a suitable brand showing the quantity and quality contained in each of said packages, of which an accurate account shall be by him filed in the office of the commissioner of the State land office.

SEC. 5. The compensation and fees for such services, above provided for, to be performed by said weighman and inspector and assistants, shall not exceed one-eighth of one cent per pound for the beet sugar so examined, weighed, and branded by him, nor shall they receive to exceed the sum of three dollars per day for any one day's service actually performed as such weighman and inspector or assistant. He shall give a bond with good and sufficient sureties in the sum of not less than two thousand dollars to the State of Michigan, contingent upon the faithful performance of his duties, said bond to be approved by the secretary of state, and he shall also take, subscribe and file in the office of the secretary of state the constitutional oath of office. The said fees of compensation together with the cost of said brand and all analyses that the said weighman and inspector shall be required to make shall be borne and paid by the persons, firm, or corporation claimant of said money; the said weighman and inspector shall perform all duties pertaining to his position in an impartial manner, and shall furnish and file with the commissioner of the State land office, also with the manufacturer of said beet sugar, a monthly statement in duplicate of all sugar so manufactured by said person, firm or corporation. The said weighman and inspector shall, upon receipt of beets at such manufactory, select such samples of beets as he deems fair and equitable, and shall keep an accurate record of the gross weight of said samples, and shall

estimate the per cent of said gross weight to be deducted therefrom as a reasonable and fair allowance for dirt and dockage, and he shall also test, or cause to be tested, said samples to ascertain the true per cent of sugar they contain, and make a record of the same. All beets from which samples have been taken shall be promptly weighed and an accurate record of the gross weights of the same shall be kept, also of the number of pounds to be deducted for dirt and dockage as fixed by the per cent of dirt and dockage of the samples, and also of the pounds net weight so obtained, and said net weight and the per cent of sugar as determined by the test of the samples shall be the basis of settlement between the buyer and seller, and in order to obtain the bounty provided by this act the buyer must pay at least four dollars per ton for beets containing twelve per cent of sugar, and a sum proportionate to that amount shall be paid for beets containing a greater or less per cent of sugar.

SEC. 6. When any claim arising under this act is filed, verified, and approved by the commissioner of the State land office as hereinafter provided, he shall verify the same to the auditor-general of the State, who shall draw a warrant upon the State treasurer for the amount thereof payable to the person, firm, or corporation to whom said sum or sums are due.

SEC. 7. That the sum of ten thousand dollars be, and the same is hereby, appropriated from the general fund in the State treasury not otherwise appropriated, to be known as the beet-sugar fund and to be expended under the direction of the commissioner of the State land office as herein provided, and the money for payment under this act shall be drawn from the State treasury on the requisition of the commissioner of the State land office, which shall be presented to the auditor-general, who shall draw his warrant on the State treasurer therefor, and the auditor-general shall incorporate in the State tax for the year eighteen hundred and ninety-seven the sum of five thousand dollars, and for the year eighteen hundred and ninety-eight a like sum of five thousand dollars, to be assessed, levied, and collected as other State taxes are assessed, levied, and collected, which sum when collected shall be placed to the credit of the general fund to reimburse it for the sum herein appropriated: *Provided*, That if the amount of bounty shall exceed the amount of ten thousand dollars for the years eighteen hundred and ninety-seven and eighteen hundred and ninety-eight, that the deficit be paid from the general fund not otherwise appropriated.

SEC. 8. Every person, firm, or corporation that shall erect and have in operation in this State a factory for the manufacture of sugar from beets with a capacity of two thousand pounds of sugar or upwards per day while this act is in force shall be entitled to receive from the State the sum of one cent per pound for all sugar manufactured from beets at such factory for a period of at least seven years from the taking effect of this act.

Approved March 26, 1897.

"Under the stimulus of this bounty nine factories have been erected in our State, and more projected in the near future. The comfortable price paid in cash at their very doors made this change in crop rotation very acceptable to the farmers. The addition of another to the three cash crops on the farm—meat, wheat, and wool, and now sugar—was welcomed by intelligent farmers, and the price of farm lands increased in the vicinity of the factory."

All around these factories the average price of farm lands in the vicinity arose \$10 an acre. I thought that was a pretty good barometer to measure the value of the land as influencing agriculture.

(Continuing to read:) "Inquiry was made of a farmer who had just unloaded his beets at Bay City: 'How do you like raising beets?' 'Pretty good. Look at that pass book and you will see my beets average for 9 loads 14 per cent of sugar and I get \$4.50 a ton cash.' 'How many tons to the acre?' 'Twenty.' 'Then you get \$90 an acre for your beet crop. How does that compare with dollar wheat?' 'Dollar wheat ain't nowhar.'"

"Only one factory has received the benefit of this bounty. The Michigan Sugar Company, of Bay City, received in 1898 \$28,451.07. No bounties were paid in 1899 because no money was appropriated for this purpose, but claims for bounty that would call for \$300,000 are pending for the bounty of 1899. So large a demand upon the State treasury, with a large prospective increase year by year, led the legislature to reduce the bounty to one-half cent per pound, appropriating \$200,000 to pay this bounty and repealing the act of 1897 with its 1 cent a pound bounty. The governor vetoed this bill, leaving the State without funds to pay the bounty, yet leaving the bounty law in full force. What will be the outcome of this unfortunate conflict between the legislative and executive powers of the State is yet uncertain. Whether the State shall finally resort to the speedy, respectable, and modern form of repudiation by having the courts declare the act unconstitutional remains to be seen."

Q. (By Mr. CONGER.) Now, touching the possible repudiation of that law or its being declared unconstitutional—repudiation of the bargain on the part of the State—what is your opinion of the necessity of a bounty for the continuation and permanency of the industry?—A. I do not think the 1 cent per pound bounty is necessary at all. I think that for 2 to 4 years a bounty of from a quarter to a half cent a pound would be sufficient to establish these factories and get them in full operation, and that from that time on they will be self-sustaining. A permanent bounty is not required, in my estimation.

Q. It is a fact, however, is it not, that as a result of the enactment of this law offering the bounty, the most of these factories in Michigan were established in 1 year?—A. Yes; they would not have been established without that bounty.

Q. It was the bounty, in your opinion, that induced it?—A. That was the governing cause, yes.

Q. (By Mr. A. L. HARRIS.) What is your opinion in regard to a tariff or national bounty to encourage the industry?—A. That is bringing me to Washington rather than to Michigan. Upon a general discussion of a bounty law, I hardly feel like entering; that is, the tariff law, I mean.

Q. Is the present tariff law satisfactory?—A. If it was declared entirely free—all tariff removed entirely—and we were open to the competition of Europe, which is offering an export bounty, why we would be stuffed with sweetness, to say the least. We would have sugar cheap, but no large production of sugar. I think the tariff law is a very safe thing, and should be continued. I am a tariff man.

Q. (By Mr. CLARKE.) If we did not have a large production of sugar, would it be likely to remain cheap very long?—A. I do not know; I am a little doubtful. I know that when you give one a chance to crowd another to the wall, he is likely to go to the wall.

Q. (By Mr. A. L. HARRIS.) The result would be much less production?—A. Undoubtedly. If we cut down the price of sugar below the cost of production here, I think the effect would be disastrous. But still I do not discuss this question from the political point of view.

Q. From the economical point?—A. Politically and economically we join hands somehow or other or touch elbows at least.

Q. What I was trying to get at is this: Would it be possible for the American sugar industry to sustain itself without some encouragement either in the way of bounty or of tariff?—A. I think if it was very thoroughly established and organized and in successful operation, and with harmonious action between the farmers and factories, that we would not be very dependent on the tariff ultimately. We would ultimately be entirely independent of it, I think, but it would not be in the immediate future. (Continuing to read:)

"With the large number of factories, present and prospective, fear has been expressed that there might be danger of overproduction. Inquiry was made of the director of the Michigan Sugar Company as to how much sugar his factory would turn out in the year. 'Six million pounds.' 'So large an amount will go far to supply the needs of the State.' 'If we can produce 7,500,000 pounds, that will only supply the needs of the counties of Bay and Saginaw.' The use of sugar is constantly increasing and will keep even step with increasing supplies.

"Our factories produce sugar so pure as not to need refining, but is ready for table use just as it comes from the factory. In German parlance, 'Sugar of consumption and not sugar for refining.' It does not have to pass through the hands of the sugar trust, and thus escapes the exactions of that great monopoly. Our only untaxed white sugar is the beet sugar produced of such excellence as not to need refining. This is our only way of escape from the sugar trust. The supply of cane sugar has been cut off from the West Indies and Philippines on account of the Spanish war; none reaches us from the Sandwich Islands, being retained for use on the Pacific coast, and Louisiana makes no more than is required by her people. The question remains. Shall we use our home product or depend upon beet sugar imported from Germany and France by the sugar trust, paying any tax that monopoly may impose?"

It was with reference to that that I brought in these samples of beet sugar for the commission to see that it does not require refining. That from Michigan now is as it comes from the factory without refining.

Q. (By Mr. CONGER.) Have all of the factories in Michigan been as fortunate in producing sugars as fine as the samples you have presented?—A. No. Unfortunately one fellow used German machinery and a German chemist to run it, and they produced some very miserable sugar. When the sugar made by their factories had gone into the market—Chicago, for instance—prior to this time a wholesale grocer told Professor Smith he did not have to open the barrels after the first instance in order to know what the Michigan sugar was. All you needed to see

was on the head, "This is Michigan beet sugar," and it was sold at once. But some of the sugar made from this factory at Caro, made under this German administration and by German machinery, was brought there. It was ring-streaked and speckled like Jacob's cattle, and it hurt the whole business of Michigan, because it destroyed the general confidence in the Michigan product. But the most of it is just like that I have placed before you.

Q. You place the responsibility for the poor product on the machinery?—A. On the machinery and the man at the head of it. He was a Dutchman with a Dutchman's ideas, that came over with the idea that Michigan people did not know anything, and he was very sure that he did know everything, and the result was disastrous.

Q. Is it your idea that the machinery for the manufacture of this beet sugar which is made in America or in the United States is better than the German machinery?—A. Unquestionably better—no doubt about it whatever.

Q. Is the factory of the Michigan Sugar Company at Bay City equipped with American or German machinery?—A. American machinery, and the same at Rochester and at Alna. They have turned out sugar of most excellent quality.

Q. Which of the Michigan factories has made the greatest success?—A. The Michigan Sugar Company's factory at Bay City, or at Essexville, right close by Bay City. It was the first in the field and has been very wisely managed; less friction between them and the farming community than anywhere else. Mr. Cranage, the manager, has been very wise and conciliatory. He told his men, "if there is a question between you and the farmers, a doubt, give the farmers the benefit of that doubt, and let us secure the confidence of these people." He succeeded in doing that, and I think it was a very wise move.

Q. That factory has been in operation how many seasons?—A. Two seasons.

Q. And the other factories of Michigan only one?—A. One.

Q. (By Mr. CLARKE.) This sample of Michigan beet sugar from the Michigan Sugar Company at Bay City is a fine white granulated sugar. So far as I can see it is fully equal in appearance to the refined granulated commercial cane sugar made by Havemeyer of New York. Do you consider that a fair sample of the general product of the Michigan mill?—A. I do, yes; a very fair sample and something to be proud of. The question has been raised—I attribute it to the sugar trust—suspicion has been thrown out that this sugar, while it will do for sweetening things on the table, is not as good for preserving and things of that kind. I took some of this sugar and passed it over to the ladies' department in the agricultural college and asked them to test the matter in regard to the preserving qualities. They made up various things, and among others some specimens of fruit jelly; they sent me a specimen of the fruit jelly, and I must confess, judging from the looks of it, that it was very much in danger of quick consumption. It was pretty hard to resist the tendency to eat it.

Now, this exemption of our sugar factories—the exemption of our domestic supply of sugar from the sugar trust—I consider one of the best things to be secured from the whole enterprise—deliverance from that monopoly.

Q. Some of the people who own sugar stock say the trust will get the control of these beet-sugar factories. What is your opinion about that?—A. Well, they will have to pretty nearly buy up the whole people, and if they will take the whole people into their trust perhaps we can trust them.

Ladies have come into my laboratory and spoken about this suspicion. They have sent out little packets of a pound or two or three from Havemeyers and state that this is the sugar that is to be certainly relied on. The ladies have come into my laboratory and looked at this beet sugar and said: "Well, beet sugar is it?" "Yes." "Is it sweet?" "Yes." "Can we use it for sweetening things?" "Yes." "Well, I did not know beets would make anything like that." "Well, my lady, how long have you been using granulated sugar?" "Two years." "In all human probability in the 2 years you have used nothing but beet sugar. The supply was cut off from the West Indies by the war. We did not get very much from the Philippines during the war. All that was produced in the Sandwich Islands, pretty much, is used up on the Pacific coast for supplying their wants; and the amount made in Louisiana is no more than sufficient to supply Louisiana and the States immediately surrounding it; and the great bulk of our sugar that we have been using has come from Europe, and is produced from the sugar beet."

Now, if we can obviate any necessity of our paying tax to Germany or the Havemeyers or any one of that class, so much the better for Michigan and the United States. I speak for Michigan, because we are chock-full of the beet sugar question in Michigan, and it naturally crops out. (Continuing to read:)

"Michigan has the physical basis for producing beet sugar of the highest quality and in unlimited quantity. We have the soil and climate, the coal, limestone, and pure water, the intelligent farmers and wide-awake business men required for so

great an industry. Michigan no more needs to import sugar than to send abroad for flour.

"There are two points in the relations of farmers to factories where misunderstanding and friction may spring up:

"1. Tare, or deduction from gross weight as allowance for adhering dirt and insufficient removal of the crown of the beet, is largely left in the hands of the weighman, and must depend upon his honesty and good judgment. But this is a matter which is open to the direct inspection of the farmers, and any great injustice would soon receive attention from the parties interested.

"2. Marc, or the deduction to be made from the amount of sugar found in the beet juice to offset the nonsaccharine solids in the beet in order to determine the actual amount of sugar in the beets, is a subject demanding careful consideration. This is a matter that does not come directly under the observation of the farmers, and they must take it on trust. It is a matter easily slurred over, and the farmer may be defrauded to an extent he little suspects.

"The marc adopted by the chemical division of the Department of Agriculture is 5 per cent, and chemists generally agree with Dr. Wiley. The examination of Michigan sugar beets in this chemical laboratory gives a factor almost identical with 5 per cent. The students in our beet-sugar class have examined the subject carefully, but the beets used had been five months stored in a cellar, were somewhat wilted, and gave too high a per cent for marc. The average results, reported by 7 of these students, are as follows:

	Per cent.
White.....	5.30
Skinner.....	5.06
Bauer.....	5.80
McKinney.....	5.57
Hargrave.....	5.58
Dooley.....	5.75
Westover.....	5.20
Average.....	5.46

"Making allowance for the dried condition of these beets, it would seem that 5 per cent marc for these beets as they came from the soil would be a fair allowance.

"One of our senior class chose 'The composition of sugar beets' as the subject for his graduating thesis, using beets that had likewise been stored for several months. He found as the average marc for such beets in 33 determinations 5.45 per cent. The marc by Pellet's Method (10 samples) was 4.93 per cent. All these trials were by use of water in removing sugar from the pulped beet.

"In extracting the sugar by the alcoholic method he found the process less satisfactory, because the sugar was not entirely removed by the alcohol, water washing out sugar from the residue. Sugar is not extracted from beets in manufacturing by alcohol, but solely by water. What sense in using alcohol in determining the marc? Why not use water in both cases and thus be consistent?

"The factory may arbitrarily select a marc to suit itself, quite different from that of the chemist, and sometimes without notice to his patrons. Instead of 5 per cent for marc, suppose he selects 10 or 12 per cent, and even more, and the farmer is without notice of this serious cut in the estimation of his produce, serious injustice may be the result."

These are not idle figures; they are actual figures, so far as quotations from Michigan are concerned. (Continuing to read:)

"If in addition the factory uses the unreliable alcohol method in estimating the marc, the wrong may be increased. It is possible that the factory may offer large prices for beets and extra inducements for patronage, and yet even up matters by assuming a marc of 7 to 10 per cent beyond what is just. Dr. Wiley, at the 'round-up' of farmers' institutes at Ann Arbor, made the remark that 'Any marc on sugar beets beyond 5 per cent was robbery.'"

Q. (By Mr. CONGER.) Have the deductions for marc that have been put upon you by the factories in Michigan been the cause for much dissatisfaction among the farmers?—A. It has become a very serious thing; not only dissatisfaction, but suspicion.

Q. Do you think there is a tendency on the part of the factories to increase the percentage of marc?—A. There is. I am informed there is one factory that has announced that they would use a deduction of 16 per cent, one-eighth of the total product deducted for marc. Five per cent, or one-twentieth, was what we considered to be ample. I am afraid of the influence of this thing creating division and strife and want of confidence between the farmers and the factories, and it is

upon this especially that the success of the sugar factories and the sugar-beet production in Michigan is to be relied upon.

Q. What is being done, if anything, among the beet growers to meet this dissatisfaction?—A. Well, this came out at our round-up meeting at Ann Arbor in March of this year, but I think that there will be a serious overhauling and a very thorough understanding between the farmers and the factory men before confidence is restored—before successful cooperation is secured.

Q. Is there any tendency toward or effort being made to bring about organization among the beet growers?—A. Not that I am aware of at present. It is too early for that to organize itself—get itself in shape. It will come; no question about that. That organization will come, and a demand for a fair and honest understanding between the factories and the farmers as to what deduction shall be made for the marc and for the tare. There has been some bitter talk about the tare. The tare men or the weighmen were appointed by Land Commissioner French, and some claim that a little favoritism was used there, but I do not take any stock in that; but he appointed them, and they are supposed to be the honest and fair representatives as between the farmers and the factories. Now, some of the factories have offered to let the farmers elect their own weighmen and tare men; but the marc, that comes on the chemical side, and the farmer is not able to cope with it.

Q. Well, this is a new industry in Michigan—that is, new to the growers of beets—and it is one, I should think, the farmers should need education in. Is there any organization along those lines, or any effort being made through farmers' institutes or other organizations to extend education in the way of the best methods to raise beets?—A. No; only through the discussions which we have in the farmers' institutes and the farmers' clubs and organizations of this kind, and granges of these kinds, coming up for discussion in these various bodies, and the thing is being agitated, and the more agitated the more we secure organized effort.

Q. The farmers' institutes, at least in Michigan, as I would judge from this round-up meeting at Ann Arbor, have given considerable attention to beet sugar culture, have they not?—A. Yes; largely. It has been discussed in every locality where people are interested in it and in a great majority of the counties, and people are interested; they have that brought up as one of the points for discussion, and it is pretty well ventilated.

Q. (By Mr. CLARKE.) Do you recognize that the success of the industry in this country depends largely upon the attitude toward it?—A. Yes.

Q. What is the attitude of the Michigan farmers this year as compared with last year?—A. The unfortunate experience of a season of drought that we had was very unfavorable, and yet they have organized a number of acres for, I think, beet factories, but only after they secured sufficient acreage for the production of sugar beets for this year: so I think they are recovering from the panicky condition they had of the growth of last year, and they are recovering confidence and are going to give it another fair trial; and if they do, and they have a season which is not so full of disasters as was the year preceding, it will come out favorable, and we shall get the confidence and cooperation of the farmers and of the factories. The question, indeed, has been discussed, as you are aware, a good deal, in regard to the desirability of the farmers entering into cooperation with the factories, agreeing to furnish the beets and then to receive such and such proportions of the results of the product of it, and that is a very hopeful sign. It can be carried out, and if you can get the farmers themselves interested in this matter, why you are going to prevent this kind of strife, and so the factories are, too. You have got to pay them prices or they won't raise the beets, and then the factories could have nothing. It is just like the strifes we have in other industries. That is no foundation, because the factory, or the most available elements of it, is capable of easy transportation from one part to another; there would be only the shell left behind, which would be a dead loss; so an effort of the farmers to establish a corner on the matter by refusing to raise beets would not give any good results. So far as the factory is concerned, of course, there is a certain amount destroyed, but the factory is not as helpless as the farmer thinks on the outset. The factory can move—can move the great mass—although with expense, of course; but they can remove the exceedingly valuable plant to other localities, leaving behind simply the shell.

Q. Has cooperation been tried in Michigan?—A. No; that is a thing of the future.

Q. Has the system of contracts for a term of years been tried?—A. No; it has only been, as far as I understand, contracting from year to year. The system of cooperation has been tried, I think, very thoroughly in Germany. I think Dr. Wiley can tell us something about that, and I would like very much to have Dr. Wiley make some statement in regard to this question of marc, which is the most important question in Michigan at present.

Q. (By Mr. CONGER.) I would like to go back for a moment to the case of the farmer from Bay City that you quoted. I think in your paper you stated that he raised 20 tons of beets to the acre and received \$90 for the same. Now, is not that an extraordinary yield?—A. Yes.

Q. What would be a fair yield per acre?—A. Well, the crop we produced there on the college farm—the average crop—is 14 or 15 tons to the acre. We call that a very fair crop, and that is what I have rather felt we should ultimately settle upon as what would be expected.

Q. And what is the rate paid per ton under the bounty law in Michigan?—A. Four dollars for 12 per cent beets, and an increase of 50 cents for every additional per cent.

Q. What per cent beets did you raise on the college farm when you raised 14 tons per acre?—A. The sugar content was 15 per cent, I think.

Q. Under the provisions of that bounty law this would have been worth how much per ton?—A. \$5.50 a ton.

Q. (By Mr. A. L. HARRIS.) Can you give the information as to what it would cost the farmer to raise a crop of beets?—A. Well, it is very difficult to get from a farmer an actual statement. The experiment was tried by the college, by keeping an accurate account of expenses for the raising of beets, and the beets as raised cost very nearly in the vicinity of \$30 an acre.

Q. That, at 15 tons to the acre, leaves a very nice margin for the farmer?—A. Yes.

Q. Will the farmer be apt to strike while there is that profit?—A. No, I do not think so. But maybe he will strike for more acres—larger investment.

Q. As soon, then, as factories deal fairly with the farmers there won't be much trouble for raw material?—A. I think not. If we get amicable and hearty relations between the factory and the farmer, and we get any such productions as we consider to be the average, there will be a very successful working between the two.

Q. You use the most improved implements in cultivating the beets on the farm?—A. Yes; the best we can find.

Q. Is the American implement an improvement over the German implement?—A. I think so. I have never used the German implement. Dr. Wiley is authority on that. But judging from what I saw imported from Germany, I should say the American implements are better.

Q. In what respect?—A. Well, in the lightness and finish and efficiency. They do better work, cleaner work, and more complete work.

Q. With less draft?—A. Less draft, and less manual exertion on the part of the man who handles the machine. The cultivators, for instance, are more satisfactory than are the clumsy and what we sometimes term the wooden machines of Europe.

Q. Do you plant by drill or by machine?—A. By machines, yes; drills.

Q. You cultivate by machines?—A. Yes; we plant the seeds very heavy; put on a heavy supply, not less than 20 pounds to the acre, in order to get a continuous row of the beets; so when you come to cultivate you crosscut out, leaving only 2 inches square in the row of the beets which are not removed; and by this cross cultivation we have just enough then, by carefully picking out, to leave a single beet once in 8 inches, for example, for the growth of the crop, and in that way the process of the weeding out and thinning out has been largely reduced. In Bay City they have largely employed the foreign women and children—wives of the Polacks—who are very efficient in doing that kind of work, and work very cheap. This man who I said got his \$90 for an acre of beets paid \$14 for thinning; and the man who stood by and listened said, "You paid an enormous sum for thinning. My son-in-law had 50 acres and got it thinned out by Polacks for \$4 an acre."

Q. (By Mr. CLARKE.) Cross cultivation, then, takes out a large portion of the surplus beets?—A. Oh, yes, very large; but if you have so sparse an arrangement of seeds in the drill when you come to crosscut to cut out, you have got a blank space here. That is so much loss—loss of the plant there, and in such development of the neighboring plants it causes them to grow too large, and an overgrowth gives less sugar, so there is no economy in the use of small amounts of seed. That is one of the troubles with our farmers. They say there is no use of wasting so much seed; it costs \$2 an acre for the seed, and nineteen-twentieths of the beets are taken out and thrown away. That is too much waste. I think I know enough about farming that I can put in seed and save one-fourth that amount of seed. Well, the great trouble with it is the farmers; well, they say they know how to farm; they have raised beets; and they rather resent the idea of anybody giving instructions on that point. That is one of their weaknesses—not receiving good advice, from their pride, or opinion, or practice.

Q. How many inches apart do you plant the rows?—A. Oh, we plant them from 16 to 18 inches apart, and we would have them perhaps a little closer together if our cultivators were a little narrower. We have got to have room for cultivating between them. All that was done by the hand hoe or hand cultivator, but 16 to 18 inches we consider a very desirable distance apart in the rows, and then 8 inches apart in the row of beets themselves.

Q. How many rows at a time do you cultivate?—A. Well, on our farm we cultivate only one row, because we have just got a 1-horse single cultivator; but if we go into business on a large scale we will have to arrange to cultivate three to four at a time.

Q. Your cultivator should take just as many rows as the drills would plant?—A. Yes.

Q. Now, you speak of cross cultivation. Do you mean you can run an implement or machine across the rows?—A. Take out those extra plants and leave just simply a block, say 2 inches square, in the row to hold the beet you want to save. The farmer does it frequently by going along with a hoe and taking a slice with the hoe and leaving blocks along for the distribution of seed; but when we come to do this on a large scale for commercial purposes and have commercial objects in view, we shall have these cross cultivators to cut out these blocks and leave blocks behind. That will be the instrument for saving a large amount of this finger work.

Q. Then thinning would be reduced by taking extra plants cut from the same seed?—A. Yes, very largely; no, there will be more than that, because they have probably more than one seed in a place, and a single seed may throw out one, two, three, or four plants; but in the two inches of thorough planting you would have probably more than one single—we call it the fruit of the beet.

Q. I would like to know something about the value of the by-product—pulp, for instance.—A. The pulp in the first place was given away to the farmers who would remove it; they took it back. The idea of the arrangement was to carry a load of beets there and take a load of pulp back, and it was given by the factories to the farmers who would take it away. That is, they would even have it arranged so as to run it out on cars and so arranged as to dump a wagonload right in the farmer's wagon, and he would carry it off. I do not think our farmers have awakened sufficiently to the value of this as feeding material, not alone, that is, by itself, but feeding in connection with other food, as, for instance, in dry food and grain, for fattening of stock. Now, in Nebraska they were using that very largely for feeding stock and fattening steers for the market, and the most delicious and juicy beef in the world was made out of pulp and prairie hay. That is all that is used for cattle.

Q. Without any grain?—A. Without any grain. They ate a very large amount of it. That was the condition I found when I visited the factory there in 1891. I presume that undoubtedly grain was introduced in finishing the feed as an element of food, but at the time I was there they were feeding just pulp and prairie hay, and about as healthy and thrifty a flock of steers as I ever saw was fed in that way. It was found to be exceedingly valuable, so far as the production of milk was concerned, and a great flow of milk was secured by the succulent food; but I do not think the farmers adequately realize the real feed value of it, and the especial value of it by bringing back on the land through the intervention of stock feeding the manure that comes through the process of raising stock. There in Bay City I was astonished to find that the molasses left behind, they let run right in the river, and paid no attention to the carrying off of a large amount of potash salts, and a very large amount of exceedingly valuable substance for feeding purposes.

Q. (By Mr. CONGER.) Have they abandoned that way of doing it or are they still following it?—A. They will abandon it without any question.

Q. Is there any difficulty about preserving this pulp or must it be fed fresh?—A. Oh, it can be siloed and kept a long time. A little will decay, but it will keep better than common corn ensilage. They are at Bay City trying to form a company and making a plant for taking this pulp and drying it, and thus preserving it in dry form for feeding purposes, enabling it to be carried for a distance by rail and sold in the open market as cattle food.

Q. (By Mr. A. L. HARRIS.) Is it valuable for sheep?—A. Yes; any class of stock except hogs. I do not know as it has ever been tried for hogs, but all ruminants relish it very much.

Q. (By Mr. CLARKE.) Much odor from it?—A. No. We have had some at the college that has been there three or four months, and there is not much smell about it.

Q. What proportion of the beet crop is returned to the soil?—A. Well, in many cases none is returned. There is a fatal defect in the agricultural arrangements.

The whole should be returned; that is, as far as possible. The beet tops and beet crowns undoubtedly should not be ever taken off the farm, should be there as a fixed element, because it has so large amount of mineral substance. The pulp has less of this because by the process of the extraction of the sugar by diffusion a good deal of the soluble soils are taken out and reappear finally in molasses, and there is the waste, allowing the molasses to get away, not so much as food, but especially for loss of manure matters.

Q. Can exhausted fertility of the soil be restored by vegetable and leguminous plants?—A. Yes; and the lost potash and phosphoric acid has got to be returned by some form of commercial fertilizers. In certain portions of Germany—for instance, North Germany—I am told by my son who has spent some time there that the land is a light, sandy soil and, for the successful raising of crops, requires a large amount of fertilizing material; but that is not the condition we find in most of our soil. In Michigan, to be sure, we have jack pine plains, which for all such purposes are useless, requiring an amount of expenditure for fertilizing material that would never be remunerated by crops.

Q. If the pulp and molasses were taken to the farm and utilized in the best way would they restore the fertility of the soil?—A. Well, they will keep up the fertility of the soil. What I claim is, there is a natural development of the fertility of the soil by natural changes which take place in the soil. The soil is a dead and inert mass. The plant food, the potash, and phosphoric acid, and lime, and all these materials become more and more available by processes which go on under natural conditions of the soil—chemical changes which go on in the soil. Now, a certain amount of fertility is thus secured and a dividend is made; but still you may say, year by year, nature rises for this purpose, if you restore it, but you have taken out of the land a thing that is there, and if you add to it, why you are building up the fertility of the soil, so you are getting a richer soil from year to year whatever the waste on it is. I was struck by a remark made by Farmer Luce there in our State. He said he had cultivated a farm for 40 years, with constantly increasing fertility of that farm, and never had bought a pound of commercial fertilizer in his life, but he had sold from his farm only finished products. He did not sell off the hay, corn, cornstalks; all coarser material he kept and fed it to the stock; and the stock itself, and wool, and butter, and cheese, and occasionally a little wheat—these materials were all he proposed to sell from the farm, and he was keeping up his farm with continually increasing fertility for 40 years, and he said it was a rich farm to begin with, and he never bought a pound of commercial fertilizers.

Q. (By Mr. A. L. HARRIS.) Is it more easy to keep a rich farm in a high state of cultivation than a poor farm?—A. I think Governor Luce would bring almost any farm in a rich condition, with his foresight and readiness to secure these results.

Q. (By Mr. SMYTH.) Has he made it profitable under these circumstances?—A. Oh, yes; Governor Luce is a man that won't fail in any sense whatever. He has enriched himself and has enriched his people by his knowledge and success and the diffusion of the knowledge which he has from his own experience. We call him one of our tillers of agriculture, and he is a good citizen in Michigan. We are very proud of Governor Luce.

(Testimony closed.)

WASHINGTON, D. C., May 15, 1900.

TESTIMONY OF MR. JULIUS E. ROGERS.

President of the Binghamton Beet Sugar Company.

The commission met at 2.07 p. m., Mr. A. L. Harris presiding. At that time Mr. Julius E. Rogers was introduced as a witness and, being duly sworn, testified as follows:

Q. (By Mr. A. L. HARRIS.) You may state your name, your post-office address, and your occupation.—A. Julius E. Rogers; post-office address, Binghamton, Broome County, N. Y.; occupation, president of the Binghamton Beet Sugar Company.

Q. Are you a grower of beets also?—A. Yes.

Q. How long have you been president of your company?—A. Since it was organized, in the spring of 1893.

Q. How many years has your mill been in operation?—A. We have been in operation two seasons and commencing on the third.

Q. If you have any points that you would like to dwell upon in connection with this industry, you may take them up in your own way, and we may interrogate you as you go along.—A. You, of course, are after all the information you can get in relation to the industry, and its bearing upon the agricultural interests of this country. Now, I feel, in the two years we have been at work, that we have solved some of the problems in relation to it. The industry is comparatively new in this country. The first factory established in New York State was in the season of 1897; that was built at Rome. For two years previous to 1898 I had become very much interested in what I believed to be the fact that New York State could produce her own sugar. I procured something over 100 pounds of seed and distributed it among the farmers of Broome County and adjoining towns, asking them for a sample of the beets grown from the seed, that I might have it analyzed in the fall. I received about 50 samples and sent them to Cornell University where they were analyzed, and that analysis showed us that we had the soil and the climate which would enable us to grow beets sufficiently rich in sugar to pay to manufacture it, and on the strength of that and an analysis made at Cornell University from many samples over the State from seed which they distributed—different parts of the State—we organized during the winter of 1897-98, the Binghamton Beet Sugar Company. We built a factory in the summer of 1898 and manufactured sugar from about 10,000 tons of beets that fall. This last fall we manufactured sugar from about 13,000 tons of beets, and we are satisfied from the experience we have had that our expectation was correct that we had both the climate and soil that would enable us to make the beets, and that we can manufacture them in New York State as cheaply as they can be manufactured anywhere. The two products of importance in manufacturing beet sugar, other than the beets themselves, are principally coal and limestone. These are the two elements which go into the manufacture of sugar from beets. We have the limestone in abundance, and we have the coal very near to us.

Q. The coal is for fuel?—A. Power, steam.

Q. What do you use the limestone for?—A. We can not buy the lime burnt; we have to burn it because we have to have the carbonic acid gas that comes from the burning for the clarification, and the lime, also, which is the milk of lime, which we mix with the juice to take out the impurities. So the two principal elements, aside from the beets themselves, are limestone and coal.

Q. Limestone is an important element or factor?—A. Very. We consume in coal about 13 per cent of the amount of beets and in limestone about 11 per cent. So that the consumption of limestone and coal are very important elements and the factory must have them—must be in a position to procure both limestone and coal at a reasonably low figure delivered at the factory—in order to insure its success.

Now we feel confident, from the experience of 2 years, that the success or failure of the beet-sugar industry in this country is emphatically with the farmer and of it. As I have said, there is no question but we can grow the beets sufficiently rich to pay to manufacture them into sugar, as the beets which we manufactured last year gave us an average per cent of sugar of between 12 and 13, and that was sugar in the beet, not the analysis that Dr. Wiley was speaking of, this analysis of between 16 and 17 and 18, which is the sugar in the juice. Then the professor, you remember, spoke of the amount of solids and the amount of crystallized sugar, giving the per cent as 80. For instance, if he had a beet that would analyze 16 with a per cent of 80, he would get 16 per cent of crystallized sugar; but with the average farmer, who has been in the habit of growing corn, potatoes, wheat, rye, oats, he could prepare his ground somewhat carelessly, put in his seed, and go off and leave it until harvest time, and he must have a good deal of education before he can successfully grow sugar beets.

Q. Is that education needed among your farmers?—A. Emphatically; and many of the farmers are going to make a success at growing their beets so far as I have had any means of knowing.

Q. (By Mr. CLARKE.) Is that education difficult to acquire?—A. It is not difficult to acquire except as the average farmer is difficult to teach. The average farmer does not take kindly to new ways.

Q. (By Mr. A. L. HARRIS.) With a careful, intelligent farmer are beets difficult to raise?—A. No; they are not to the most intelligent farmers—to the farmers that do their work in the best way. The farmers who take the best care of their crops are those who are making the most success of growing sugar beets. We have contracts now for about 2,200 acres for this next year—between 2,200 and 2,800. I should think that from 70 to 75 per cent of these contracts are with old growers, and fully 60 per cent of them are those who have grown beets for us two years. But the man who puts in his seed, as I have said, and goes off and leaves his crop is sure to make a failure of growing sugar beets. It means very emphatic culti-

vation and very much more work than the average farmer puts on the average crop.

Q. Is there any particular expert knowledge required in the raising of the beet, such as is required in raising of tobacco?—A. No; except in the economy of caring for the crop. Almost without exception the farmers who grew beets for us the first year, and those who contracted the second year, have stated to us that they were able to care for the crop with very much less expense the second year than the first.

Q. Does it require special preparation of the ground?—A. It does.

Q. You may briefly describe the necessary preparation, if you will.—A. In the first place, as was stated here this morning, we can not successfully grow beets on mucky soil. We can grow a sufficient number of tons, but we can not grow beets of sufficient quality of sugar. Soil that would grow wheat, corn, and potatoes will not grow good sugar beets. It requires a soil that is well drained, that is comparatively free from stone, so as to be easily worked, and it needs deep and thorough cultivation. While for corn and oats ground should be plowed only about 5 or 6 inches, for beets the soil should be worked at least 10 or 12 inches deep in order to procure the best results, as the sugar beet must be grown down in the ground if it is to be grown profitably both for the factory and the farmer. Then the seed bed must have very much more attention than for growing the average farm crop. It must be thoroughly pulverized as the first essential, and the difficult part of procuring a crop of sugar beets is to secure a full stand. In our contracts we ask our farmers to sow not less than 14 pounds of seed per acre. Professor Kedzie said they asked theirs to sow 20 pounds. Now, not more than half of 14 pounds even can grow, but we insist upon their sowing this amount that they may get a full stand—that every row may be full—and in order to insure that they must have a seed bed in as perfect condition as it can be got.

From our experience and the experience of those who have made the most success of growing sugar beets in the last two years, the cost of preparing the ground, sowing, thinning, cultivation, and harvest is about \$30 per acre. We have had very many farmers who have paid as high as \$40 and \$45 per acre in labor who have expended that amount in labor for growing this crop. We have others who have grown it for less than \$20 an acre, but it need not cost to exceed \$30.

The first year our average yield of the crops which were harvested, not including all that was sown, because some were sown and never harvested at all—but those that were harvested would average 6 tons per acre. Last year the average yield was 8 tons per acre. We fully expect, with the experience of the past two years and an average season so far as rainfall and climatic conditions are concerned, that we will get very nearly or quite 10 tons per acre as an average yield this year. But I do not think we can expect, certainly not for some time to come, an average yield of more than 10 or 12 tons per acre, and this will be secured only on good land, thoroughly cultivated.

Q. (By Mr. CLARKE.) How much do these beets net per ton or acre?—A. The conditions in New York State are somewhat different than in Michigan. Our State pays a bounty of 1 cent a pound on all sugar made from beets grown in the State, providing the farmer receives \$5 per ton for the beets: so that our contracts, all of them, provide that we shall pay \$5 a ton for the beets, and that they shall not give us less than 12 per cent of sugar. But we never have thrown out any beets because of the analysis; never had any trouble along that line whatever.

Q. (By Mr. A. L. HARRIS.) How do you determine the value of the beet when brought to your factory?—A. We determine that by analysis in the laboratory, and, as I say, we have had a few lots of beets that have not analyzed up to the standard of 12 per cent; but we take this ground—that the farmer does not know the land or the kind of cultivation that will give the best result, but it is a matter of education to him. He does not know the kind of soil or the kind of fertilizer or the kind of tillage that is going to produce the greatest amount of sugar if he has not had any experience. We are aiding all we can. We are employing men and keeping them in the field all the summer to give them that help and instruction—all that we are able. If he does his best we take his crop in the fall regardless of analysis and pay him the price provided by the State law. We have never refused any beets offered us by those with whom we had a contract, and we have only had a very few lots that have given us less than 12 per cent of sugar.

Q. (By Mr. CLARKE.) Then the farmers make a profit of \$10 an acre?—A. The good farmers. Those who have taken care of the crop have made a profit, as a rule, of more than \$10 per acre. There have been a good many failures. These came from men who either took no pains with the crop, did not follow the instructions given them, or because of their shiftless way of both sowing and cultivating the crop was a failure.

Q. (By Mr. A. L. HARRIS.) Are you reasonably certain of a sufficient amount

of moisture in the course of the season to grow your beets properly?—A. The average season, such as we have in New York State, we get sufficient moisture to give us a good crop of beets. We had the driest season last year that we have known for fully 20 years, and yet the crop was 2 tons, on an average, better than the previous year, because of the experience of 1 year in growing them.

We have in New York State a condition that perhaps does not exist in any other State of the Union. We can grow peaches, pears, apples, plums, grapes, apricots, cherries, berries of all kinds, in fact, almost every kind or variety of fruits that go on our table, except the orange and banana; and we grow them, too, in their perfection. There are no apples abroad that bring a better price than New York State apples: none that have a better flavor. Now, the soil and the climate that gives us the fruit in its perfection is exactly what we want for the sugar beet. So there are natural conveniences for this industry in this State. Our claim for our State is that we have a condition of soil and climate that will give us the best fruit and a larger variety than is produced anywhere else on the globe.

Q. You think, then, the fruit index is a good one?—A. I do, most emphatically. I also know from my own experience, not in growing sugar beets, but in growing other crops, that there is not any crop that is open to the farmer of this country from which he is sure to derive a larger income, and from which he may be more sure to receive pay for the labor he expends and a fair remuneration for the land which it takes, than the sugar beet, properly cultivated and economically cared for.

Q. (By Mr. CLARKE.) You think a profit of \$20 an acre is entirely within the range of reasonable expectations?—A. I do. I can give you an instance of perhaps one of our largest growers—Smith & Rowell, of Syracuse. The first year they contracted for 15 acres of beets. Last year they grew for us 130 acres. They are under contract this year to grow 300 acres. Quite a portion of their farm is within the corporation of Syracuse. They have been in the nursery business and they understand gardening. From the 130 acres which they grew for us last year we paid them about \$8,000, an average of something over 12 tons for the 130 acres. There is no sentiment in growing beets with them. They grow them for money, but undoubtedly they are making a greater success than many others, because they know how.

Q. Do you pay that free on board Syracuse?—Yes.

Q. (By Mr. CONGER.) What percentage of beets do you pay \$5 a ton for?—A. I was saying, in our State, by the State law, we get a cent a pound on all sugar made from beets grown in the State; but under this condition: That the factory pay \$5 a ton for the beets regardless of the per cent of sugar.

Q. You do not pay more than \$5, no matter how high the percentage of sugar?—A. No; nor less than \$5.

Q. You spoke of the production being 12 tons. Is that an average for the production in New York State?—A. I was saying that the first year our average yield from the whole number of acres from which beets were received—not from all the acres planted, because there were some failures, but from all the acres from which the beets were received—our average yield was 6 tons per acre. Last year it was 8, and we fully expect, with the experience of the last two years and an average season this year that the yield can be increased to 10 tons, or very near it.

Now, I do not believe the yield in New York State or in any State of the United States can be counted on at more than 12 tons per acre, certainly not for a number of years to come, until the farmers become more thoroughly versed in growing their beets than they are now.

One of the unfortunate things, it seems to me, in connection with this industry, is in the fact that many farmers have been deceived in regard to the number of tons they can grow, saying they may expect a yield of 20 to 25 tons, and some have estimated it as high as 30 tons to the acre. I know a year ago they endeavored to start a factory at Penn Yan, and I saw circulars published and posted for the information of farmers, that they could grow from 25 to 30 tons per acre. We have had men grow 25 tons per acre for us, but they are very exceptional cases, and it can not be done as an average yield; and when the farmer is given to understand that he can grow that amount and then does not get more than 10 tons to the acre, he is not satisfied.

Q. (By Mr. SMYTH.) Was the quality of that yield at 25 tons as good as the 12 tons?—A. Yes.

Q. Was it due to the cultivation and skill of the farmer?—A. Yes. More particularly, where we have had a failure, what has reduced the yield more than anything else is the lack of a full stand. We advise them to sow in rows 18 inches apart, and then to thin them to 8 inches—a beet for every 8 inches in the row. That is the ideal condition for a field of beets. If we can secure that on good land, and keep it clean, we can secure a very satisfactory yield. Our failures have been

due almost entirely to the lack of the rows being full, and the cultivation being poor and neglected.

Q. (By Mr. CONGER.) Did you have any difficulty in getting an acreage this season? In other words, are your farmers satisfied?—A. Not all of them are satisfied. As I stated, I think the beet-sugar industry, so far as it pertains to this country, the problems have been solved with the exception of this one problem that still remains—the farmer's end of this business. Now, there is no question that the farmer can grow the beet, and profitably, after he has learned how to do it in the most economical way, but it will require a good deal of teaching on the part of some of them, and a great deal of patience on the part of the factory, to get the farmers to grow beets that will be the most profitable for the factory and give the best returns to the farmer. There is no question about the manufacturing end of it. The factory that is sure of getting from thirty to fifty thousand tons of beets for the campaign can be almost sure of the results with conditions as they are to-day in relation to the price of sugar; but, as was stated here this morning, it matters not how thoroughly equipped a factory may be, how well it may be managed, if it has not more than half the amount of beets it ought to manufacture in one season it can not run profitably.

Q. (By Mr. CLARKE.) What is the season for running factories?—A. About 100 to 120 days.

Q. Beginning and ending when?—A. Beginning the 1st of October with us. That time would change in some localities. In California they begin very much earlier. We usually begin about the 1st of October, and then our beets, of course, have to be harvested or provided for in some way to protect them from frost about the 1st of December.

Q. Are they gathered into cellars then?—A. No, we provide sheds—storage room for the beets, and we receive them all by the 1st of December, and then we hold them from that time until they are worked up.

Q. (By Mr. CONGER.) You have followed that plan in both the seasons you have operated?—A. Yes, and expect to follow it this year.

Q. (By Mr. CLARKE.) How long will they keep well?—A. Freezing does not hurt the beet to be made into sugar; freezing and thawing will spoil it, but the beet can be frozen and if it remains frozen it does not hurt it.

Q. (By Mr. CONGER.) You allow them to freeze in these sheds?—A. The outside freezes because we have freezing weather always in December, but they are protected from snows and storms.

Q. The center of these piles will not freeze then?—A. No. Heating will spoil a beet.

Q. Do they heat in these large piles?—No. Our sheds are made with slat bottoms so that the air circulates through them, and we have never had any trouble with them heating. Heating is much more injurious to the beet than freezing. They decompose.

Q. (By Mr. CLARKE.) Do you pile the beets in large masses?—A. Our sheds are 425 feet long and from 16 to 24 feet wide, and we fill them from 6 to 8 feet deep.

Q. (By Mr. SMYTH.) What is the capacity of your mill?—A. Our factory has a capacity of 250 tons per day of each 24 hours.

Q. (By Mr. CONGER.) How many tons did you handle last season?—A. We handled 13,000 tons. We have under contract now what we think will give us 20,000 tons for this season.

Q. (By Mr. SMYTH.) The business is moderately successful?—A. Yes.

Q. You have no difficulty in disposing of your product?—A. That question came up this morning in regard to the kinds of sugar. The first year we made granulated sugar. We have a full equipment for making granulated sugar, but this last year the difference in price between the raw sugar, which is a sugar something like the middle one on this card (indicating)—

Q. (By Mr. CLARKE, interrupting.) That is a yellow coffee sugar?—A. Yes; what we used to call light brown. The difference between that and the granulated sugar was less than one-half cent, and the American Sugar Refining Company offered to take our entire product, and we sold it to them at less than the half cent difference in the price between that and granulated sugar, which was very much better for us than to refine it. It would cost us nothing to sell it. We shipped a car every day, as fast as made. It cost less to bag it, no insurance to pay for storage, and we had but one customer, and it was a good one. Now this difference might not exist every season. It was only because of the sugar war that was on that made prices as they were.

Q. (By Mr. CONGER.) What difference between raw and fine would make it more profitable to you to turn out the refined or granulated?—A. If the difference was over a half cent we should refine it.

Q. (By Mr. SMYTH.) Can you tell us something about the by-products of the

beets?—A. The by-products are a very important feature with us. The first year when we began to manufacture we gave the pulp to the farmers and told them to come and get it. They began to draw it away in small quantities, and after we had run about a month we charged 25 cents a ton, but they took only a small part of the product we made. This last year we started by charging the farmers 50 cents a ton, and we could have sold three times the amount we had. It may be interesting for you to know that many times last fall I have gone to the factory in the morning and found 60 teams in line waiting to be loaded with pulp, and many of them would stay there all day waiting for their turn. It is one of the best milk-producing foods that I know anything about.

Q. (By Mr. CONGER.) These farmers would buy it for feeding purposes?—A. We have not confined it to raisers of beets, so many others wanted it. This year we have used that as a lever for raising beets, by giving special accommodations in relation to pulp to those that grow beets. Last year I began by distributing several barrels of molasses to the best farmers and told them to try it, and I was surprised as much as they. They fed the molasses all winter. I fed about 200 head of stock and 10 or 12 horses with excellent results.

Q. (By Mr. CLARKE.) How is it fed?—A. Pour it on the feed.

Q. On hay or grain?—A. On hay or grain. It is very fattening. Our horses have never come out in the spring in the condition they are now—they are too fat to work; and on the stock that we have fed it to, both sheep and cattle, the result has been very satisfactory, indeed.

Q. (By Mr. SMYTH.) Are they fond of it?—A. Very.

Q. (By Mr. CLARKE.) Is there any flavor to the molasses except sweetness?—A. Yes; it has a very salty flavor. In fact, most of the impurity of molasses is salt, and that is what retards the crystallization of sugar in the molasses. Our molasses will analyze 50 per cent sugar; so you can see as a fattening food it is one of the best, and our farmers, very many of them, have been feeding it, and very many more will feed it the coming season, I think. There is no question at all. I have solved that to my own satisfaction, and many others of our farmers about us feel that the molasses and pulp are a very important food product, and will be used in our dairy sections to a very great advantage.

Q. Are you able to get second-hand barrels for that?—A. We had good second-hand barrels; yes.

Q. (By Mr. A. L. HARRIS.) Is it possible to convert it into alcohol?—A. Yes. I looked that matter up, thinking we might use it in that way, but I found that our Government has rated it as grain alcohol. If we could put it in as wood alcohol we could afford to make it, but as grain alcohol we could not. Paying \$2.10 tax and selling it for \$2.35 there was not anything in it to us. There is no tax on wood alcohol for mechanical purposes. But they have rated this as grain alcohol, and it would be subject to the tax of \$2.10 a gallon. Very much of the molasses in Germany is made into alcohol, although for the past 5 years there has been much less than formerly, because it has been used as a food product.

Q. You think the 50 cents you have been selling the pulp for is the full value of it as food?—A. No; I think it is worth, to any farmer who has dairy cows to feed, more than \$1 a ton. In fact we sold this year a very large portion of our pulp for 50 cents a ton put on the cars, and the farmer paid \$1 a ton freight to bring it to his place.

Q. Is it good to make a complete ration?—A. No. It needs grain with it. The stock that we have fattened this season we fed ensilage of pulp and molasses, but the molasses, you see, provides the grain ration, because the molasses has an analysis of about 50 per cent sugar, which in another form is starch, and about 5 per cent potash.

Q. Has beef practically fed on the pulp a superior flavor?—A. I do not know about the flavor, but they say it comes the nearest to grass beef of anything they get. They have complimented the beef very highly as being of excellent quality. I do not know whether the flavor would be affected or not, but it would be juicy, tender beef, and it would come very near to grass beef.

Q. Do your farmers have any trouble in getting help in the busy season?—A. Yes, that is one of the difficulties in growing large acreages of beets. Many farmers tell us they can not get help. Of course, if it could be employed for any length of time they could get all they wanted, but to employ it only for a few weeks it is difficult in some cases for them to get the help necessary to do the work.

Q. (By Mr. CONGER.) In selling this pulp at 50 cents a ton do you sell it as it comes from the factory?—A. Yes, but it passes through presses and the water is taken out of it. It is very moist, but the greater portion of the water is taken out. It passes through a spiral press which takes out the water, although it is

moist enough. It probably contains 60 to 70 per cent of moisture—perhaps not more than 50 per cent, but I think it would run from 50 to 60.

Q. When it comes from the factory it is 90 to 92 per cent?—A. The water is mixed with it then. We take the juice from the beet by diffusion and not by pressure, and of course when it comes from the factory there is a great amount of water in it.

Q. You take part of that water out before you sell it at 50 cents a ton?—A. Yes; it passes through the press. I have never analyzed the pulp to know how much moisture there is in it, but I think it would be in the neighborhood of 60 per cent. The one point I would like to emphasize is that the question of the help the farmer may be able to get in this industry is going to mean very much to him, as I am confident we have the soil, climate, and conditions that will enable us to produce every pound of sugar that we consume. Now, I was astonished when I first began to look up the question of the sugar consumption of Binghamton. I looked up how many pounds of sugar we consumed in Binghamton. We have a town of from 45,000 to 50,000 inhabitants, and I found that our sugar bill was over \$500,000 each year; that there went out of Binghamton every year to pay for sugar over \$500,000. And with our factory, thus far, we have made something over \$100,000 worth of sugar every year. If we had three just such factories we could not supply Binghamton alone. With a knowledge on the part of the farmer that would enable him to produce the beets in the most economical way our county could supply beets enough to provide the sugar which it buys.

Q. (By Mr. CLARKE.) Are most of the farmers in your vicinity native Americans?—A. Yes; and that is not conducive to beet raising.

Q. Why not?—A. Because they do not like to get down on their knees. The most successful beet raisers we have are the foreign element that are not afraid to work.

Q. (By Mr. A. L. HARRIS.) Is there any possible chance to invent a machine that will do the thinning?—A. No; I do not think there is. There is a certain amount of work that must be done by hand. The row contains very many more beets than can possibly grow. We go through with a 6-inch hoe and cut them out, leaving a little clump of beets, cutting out 6 or 7 inches between.

Q. (By Mr. CONGER.) Could not that work be done with a cultivator?—A. Yes; with a great deal of care. We have tried that with a cultivator that cultivates 4 rows at a time, and that work to a certain extent can be done by cultivation, but it is very particular work, more careful work than the average farmer will do. We found—I had charge of growing some beets last year—that it was more profitable for a man to take the hoe. Now, when you have that little clump of beets, whether it was done with the cultivator or the hoe, you have a half dozen beets close together, and the roots of these little beets are wound around each other. Somebody has to put his thumb and finger on the beet he wishes to retain and pull up the rest of them with the other hand. That is the particular part of the work, and a man has to go down on his knees to do it.

Q. Is it tedious work?—A. It is not tedious or hard work, but he can not do it standing up or riding, and the average man wants to ride.

Q. (By Mr. SMYTH.) He has to move from plant to plant on his knees?—A. Yes; we hire boys or Italians to do that work.

Q. He is practically on his knees almost all the time?—A. It is not hard work, but the average farmer does not like to do it. Why, you know there is hardly any machine to-day but the man rides.

So the one thing I am anxious about, and the one I believe is of more consequence than anything else, is the help the farmer can have in growing this crop—the help that he can get in the line of cultivation, the economy of cultivation, and to be able to secure a price that will be remunerative to him until the time comes when he can produce this crop for the least money.

Q. (By Mr. CLARKE.) This thinning process has to be gone through with once in the season?—A. That is all.

Q. What time of year?—A. We sow the beets with us during this month. Probably this year many of them are sown now, from the 1st to the 10th of June; and in about 10 days after beets are sown—perhaps 2 weeks after—when they are about 3 or 4 inches high, then we cut them out with a hoe, and then thin them.

Q. (By Mr. A. L. HARRIS.) You thin immediately after cutting out?—A. Yes.

Q. (By Mr. CLARKE.) How much time is devoted to the thinning?—A. I think it cost us last year about \$6 an acre to thin them.

Q. The process is going on for a week or 2 weeks, I suppose?—A. Yes.

Q. Do you bring in this extra help from the outside or find it there?—A. You can get all the help you want in Binghamton. The way I did last year was to establish a tent on the bank of the river and board the help, and it was a sort of

picnic for the boys to come out there. I could get three boys to come out and live in the tent and work in the beet fields, where I could hire one and send them back home at night.

Q. Did you pay by the piece or by the day?—A. By the day.

Q. (By Mr. SMYTH.) How long did they work?—A. Ten hours.

Q. (By Mr. CONGER.) What wages did you have pay to these boys?—A. From 50 cents to \$1.25 a day.

Q. According to efficiency?—A. Yes; we put them in different gangs and paid according to work, and then we charged them 10 cents a meal and lodged them under the tent, of course. The food—we did not serve any ice cream, but it was good wholesome food.

Q. (By Mr. A. L. HARRIS.) Outside of the thinning, how many acres of beets can a man till?—A. Then it is simply a matter of cultivation largely.

Q. How many rows of beets do you cultivate at a time?—A. We have a cultivator to cultivate 4 rows at a time. We sow the beets with a drill that sows 4 rows at a time, so the rows are rigidly equal distances apart, and the cultivator is gaged exactly the same, so that we have to watch only 1 row, and if we cultivate it properly we are sure of cultivating the other 3. The first cultivation we do with that, but after that we run a cultivator which only cultivates 1 row at a time, so a man will cultivate 3 or 4 acres a day. We cultivate them about once in 10 days until the leaves entirely possess the ground—that is, cover the ground over. The beet is a hardy plant and rapid grower, but it must have attention early. One day's work in the beginning of the season is worth a half dozen after the weeds have got a start.

Q. (By Mr. CLARKE.) There is no danger of the destruction of the crop by insects—as the tobacco crop and some others?—A. Not any. I presume the beet has its enemies like other crops, but we have not found them yet.

Q. (By Mr. SMYTH.) Do you have to rotate the land?—A. We have not done that yet. On our farm, which is right near the factory—in fact, the factory is built upon it—we had 20 acres of beets the first year, and last year we had 40 acres, and that included the same 20 acres that we had the year before. This year we have prepared 50 acres, and it includes the same 40 acres that we had last year. I presume we are making a mistake. I presume it can not be done continuously, but I am going to find out how far it can.

Q. (By Mr. A. L. HARRIS.) What kind of soil?—A. Sandy loam; river flats.

Q. You would consider the physical condition good?—A. Yes, and taking care of it every year. This year, from the 200 head of stock we have fed, the manure has gone on to the land. I know we are told, by experience in Germany and France, that we must not grow beets continuously on farm land, and I presume it is correct; but we must learn some things for ourselves, and we may have different conditions—a different soil—and I am going to determine how many crops of beets I can grow on the same land. I know I can grow corn 15 years in succession and just as good the fifteenth year as the first.

Q. (By Mr. CONGER.) How do you do that with corn? Use fertilizer?—A. Certainly.

Q. Artificial?—A. Manure.

Q. (By Mr. CLARKE.) Do you use any other fertilizer in addition to that?—A. Yes, we are applying, in addition to that, about 400 pounds of phosphate—commercial fertilizer—per acre.

Q. (By Mr. A. L. HARRIS.) Do you use any potash?—A. The commercial fertilizer carries an analysis of about 4 per cent of nitrogen, 8 per cent of phosphoric acid, and 10 per cent of potash, all available.

Q. High grade?—A. It is high grade, very. I had it prepared on purpose. We have taken this pains with our farmers in regard to fertilizer: In order that they may have the advantage of the best fertilizer we were able to procure for them, we have bought the fertilizer in the spring and distributed it to the farmers for the crop, and taken it out of the beets in the fall. We have provided our farmers with the seed and the fertilizer, and they have paid for it with the crop in the fall.

Q. What is the cost of that grade of fertilizer?—A. It costs \$31.

Q. How many do you apply to the acre, or rather, how many acres can you fertilize with a ton?—A. That depends on the condition of the soil. Last year we put on 800 pounds, but where the land is in a high state of cultivation, or there is a large application of stable manure, it does not require as much, and I think the majority of our farmers have used about 400 pounds to the acre.

Q. Do you use the commercial fertilizer in connection with barnyard manure?—A. Yes; but where no manure was applied they used 800 pounds to the acre.

Q. (By Mr. CONGER.) You state that of the 40 acres in beets last year 20 acres of it raised beets the year before?—A. Yes.

Q. Was the crop on that 20 acres as good as on the other 20 acres?—A. Yes; but not as good as it was the previous year. That we did not attribute to the second season of growing beets on that land, but to the very extreme dry weather.

Q. About what tonnage did you get last year per acre?—A. Between 10 and 11. The previous year we got 14 tons, but where we got 14 tons it was, in the first place, on the best of land, and had the best of cultivation. It is entirely possible to grow 14, 15, or even 20 tons of sugar beets to the acre, but it is not reasonable to tell farmers that they can grow that number of tons as an average crop for a number of acres that might be sown, for experience does not prove it.

Q. Your idea is, as far as land is concerned, that that 20 acres raised just as good beets as it would have raised if beets had not been grown on it the year before?—A. I think so.

Q. (By Mr. A. L. HARRIS.) How do you dig the beets?—A. We have what is called a lifter, made on purpose—made with a beam similar to a plow, and then instead of the landside and moldboard of the ordinary plow, it divided after going back about 2 feet; on the bottom it goes out in a circle in this way [indicating], and arms go down in this form [indicating], and on the ends there are 2 sort of spurs, about as large as my finger and in about that shape [indicating] and about that distance apart, and the edge of these is sharp, and that runs right under the beet and loosens it so that a man can take it by hand and throw it out. Another way, generally used, is a subsoil plow or an ordinary ditching plow, and some have used an ordinary reversible plow and plow the beets out with that. Then the beets have to be topped and the tops have to be cut off by hand. Now, one of the most important things in the harvesting of beets is the cutting of the crown off square with the last or bottom leaf. That dotted line [indicating] shows what I mean by cutting it off at the base of the lowest leaf. The crown of a beet contains a large percentage of mineral element, of salt, when the beet is taken out of the ground, and it is not that there is no sugar in the crown but it is because of this salt, which not only will not crystallize itself, but retards the crystallization of other sugar in the beet, and that we must insist on being cut off.

Q. (By Mr. CLARKE.) Where is the topping done?—A. In the field.

Q. What becomes of leaves?—A. They may remain in the field and be plowed under, and as Professor Kedzie told you this morning, by returning the crown and leaf back to the soil you have returned more than half of the fertility that the beet has taken out in growing. But it is an excellent food, also. Cattle are very fond of it, indeed, and do remarkably well on it. It may be fed, or it may be returned to the soil.

Q. (By Mr. A. L. HARRIS.) Which is the most economical?—A. If a person had stock to feed it to, might better feed it and return the product back to the lot; but in either way. Professor Roberts, of Cornell University, makes this remark: "That the United States have been paying a \$100,000,000 a year for sunlight." On the same line Professor Kedzie told us this morning that sugar was carbon, and water, and sunlight. Sugar is partly carbon, and in taking the sugar product alone off of our fields we have taken very little of nitrogen and phosphoric acid and potash, which are the true elements of plant food; so that if we return the crown and leaves, as I say, we have returned to the soil half the fertility which the crop has taken out.

Q. You look upon the enterprise as an encouraging one, do you, at the present time?—A. I do. I have great confidence, because, as I said here, I know that there is no crop that is open to the farmer to-day from which he can realize, and be sure of realizing, the pay for the labor that he puts upon it, and a reasonable use for the land which he devotes to it, because his crop is contracted for before he puts the seed in the ground, and he knows exactly what he is going to get, and he knows it is sold. Now, the hardest thing with the average farmer is, not to grow the crop, but to dispose of it after he has grown it. They can grow wheat enough, produce corn enough, butter and cheese enough, but the average farmer can not sell it, that is, can not sell it at a price to his credit. Now, with the beet crop, it is sold before he puts the beets in the ground, and he knows what he is going to get, and it is sold at a price which, if he will produce it as it can be produced, with economy, it pays him for his labor, and pays him for the use of the ground devoted to it; and that is my confidence in it.

Q. (By Mr. CONGER.) The State of New York, you say, pays a cent a pound bounty?—A. Cent a pound; yes.

Q. Are there many of these factories in New York?—A. Only one now, and another is building. There will be two this summer.

Q. (By Mr. SMYTH.) Is that cent a pound on refined or brown sugar?—A. No, a cent a pound on sugar from beets grown in the State that polarize 90 per cent; and from each day's product we send a sample to the State chemist in Albany and the State pays bounty on his analysis.

Q. (By Mr. CLARKE.) Does all yours come up to that percentage?—A. Yes; our granulated sugar like this will polarize 96.6, 99.7, and our brown sugar, such as we made last year, such as on the card there, will polarize about 96, and the third product will polarize about 93 or 93, so that it all comes above the standard.

Q. Where are those polariscopic tests of sugar made?—A. Made by the State chemist. We send a sample every day of each day's product to the State chemist. The State appoints a man to weigh sugar and select these samples; he is in the factory all the time during the campaign, and he selects samples and sends them to the State chemist and he makes his analysis; then he makes a report to the State.

Q. (By Mr. SMYTH.) His salary is paid by the State?—A. No; by the factory.

Q. (By Mr. CONGER.) How long ago was this bounty law enacted?—A. Enacted in 1896 or 1897.

Q. (By Mr. SMYTH.) Does he work for the factory to some extent other than to do this weighing?—A. All he does is to weigh the sugar. The law provides we shall pay him \$5 a day for services while he is with the factory; but he is an appointee of the State, and is a State officer.

Q. (By Mr. CONGER.) It does seem a little strange that with that bounty as an inducement you have not more factories established there. In Michigan, for instance, in 1897, there was such a law enacted and we had 8 established the following year, or the second year, rather. Can you offer any explanation why, with this inducement in New York that is offered by the State, more factories have not been established?—A. No; I can not state except from the fact that it takes a great amount of money to establish a beet-sugar factory, and this other question of the attitude of the farmer toward the industry. Now, they will have more to do with it than anything else in relation to the matter.

Q. Have there been some failures in attempts to establish the industry in New York State?—A. There have been no failures in attempts to establish it. Rome was the first factory that was established.

Q. Was that a success?—A. I do not know whether they made any money the first 2 years, but they have stopped now, because Rome went into Canada and bought a plant there. That remained in operation I do not know how long; only capable of reducing about perhaps 125 tons of beets per day, and they got a very large part of their acreage from Wayne County; and at Lyons, which is situated in Wayne County, they organized a company this spring, and are putting up a building now, but their building is being built for a 500-ton plant, and they took the contracts that formerly had gone to Rome, and Rome has quit. Now, whether she lost any money or not, I do not know anything about that. I know nothing about this, except that I know she is not going to make sugar this next year, and the Lyons people claim they have the contracts; in fact, I know they have, because I have been on the ground—the contracts that Rome had the last year; at least, I have not been there, but I sent a man there to see about the acreage.

Q. (Mr. A. L. HARRIS.) What kind of machinery was this in the mill at Rome?—A. It was very unsatisfactory. Well, I can give you this, which will show you just the condition exactly. They had last year 9,000 tons of beets. They were 105 days in working up 9,000 tons. Our factory had 13,000 tons and were 65 days, and we sent some of our help to Rome to help them out. I think it was an unfortunate year for them. Then I think that Rome, too, only got—I do not think they got anywhere near the amount of sugar from the beets they ought to have got. As I say, we got 9.07 per cent of sugar to the ton of beets, about 180-odd pounds. Rome did not get anywhere near that.

Q. Was the trouble with machinery?—A. Yes.

Q. (By Mr. CONGER.) Was that machinery in the Rome factory of American manufacture?—A. No.

Q. Is the machinery in yours American?—A. It is both French and American. We bought part of it in France and part here.

Q. (By Mr. A. L. HARRIS.) How many men do you employ during a campaign?—A. Well, in the factory alone we employ about 35 men, and unloading beets and in the work outside about 120.

Q. Do any of these men raise beets?—A. Yes, some of the farmers who live about the factory farm some, but the majority of them do not.

Q. Could they get employment that way the year round?—A. Yes. Now, I have prepared here something along the line of manufacturing. I do not know whether it comes in line with what you want. Here is our report for 1899. Now, I want to say that, in my judgment, and I think from the experience we have all had in this country, there is not any question but what you can make sugar at a minimum cost with a 500-ton factory. That is, I think that sugar can be made cheaper per pound where 500 tons of beets are worked each day than any amount less than that. You have got office expenses, superintendent's expenses, and engineer and

certain fixed expenses which every factory carries that are not any more in a 500-ton plant than a 300, and we shall increase the capacity of our factory this year. part of it, and next year we expect to put the rest of it up, and make a 500-ton plant on that ground, for that reason.

Q. (By Mr. CONGER.) What capacity do you call the plant now?—A. We say 250; it is rated 300. We can not run 300 and run it every day; we can run about 250.

Q. (By Mr. A. L. HARRIS.) May I inquire what the cost of a 500-ton plant is?—A. It would cost about \$500,000.

Q. (By Mr. SMYTH.) This machinery you import from France—do you have to pay a duty on it?—A. Yes; 45 per cent.

Q. Was the machinery for the sugar-beet industry made in this country previous to that time?—A. It was; that is, most of it was. We thought we could procure this to a better advantage there, and be sure of getting it, than we could to procure it here. The centrifugals, granulators, boilers, pumps, and things of that kind we bought here; part of it we bought over there.

Q. (By Mr. A. L. HARRIS.) Is machinery that you bought in France manufactured in this country?—A. Yes; a factory can be equipped in this country throughout.

Q. (By Mr. SMYTH.) Can it be equipped with as good machinery as you bought in France?—A. I think so.

Q. Is it not a fact that machinery in this country is really better than that made in France?—A. Well, I think that would be subject to the manufacturer. There are some manufacturers in this country that have been making as good machinery as can be made in France, but I know of some lawsuits they have in Michigan now in relation to machinery put up there by manufacturers in this country, and it will be a very serious matter before they get through with it.

Q. (By Mr. CLARKE.) You were speaking wholly of sugar machinery?—A. Yes. There is not any doubt at all but what there are manufacturers in this country who will manufacture and are manufacturing just as good machinery as we get abroad, and there are manufacturers abroad—that factory that was spoken of this morning, put up by a German concern, got in trouble—but there are other German concerns that make just as good machinery as they do in this country. It is not the machinery as much as it is the manufacturer, and machinery can be manufactured and is manufactured in this country now.

Q. (By Mr. CONGER.) Is it not a fact that all of that machinery used by that company in Michigan was German-made?—A. I do not so understand it. At any rate there was some machinery put in factories there that was put in by Chicago concerns that had to be taken out and changed.

Q. Mr. Smith says that while the machinery was put in by an American firm, it was all made in Germany?—A. All made in Germany—I have not any definite knowledge of things there.

Q. (By Mr. SMYTH.) Just from your general knowledge of the business?—A. Yes. What I am saying of our factory, of course, I have personal knowledge of. I think I have given all the facts I have here on this paper.

Q. (By Mr. CLARKE.) How much less would it cost to equip a factory if you did no refining?—A. Very little. The difference between granulated sugar and raw sugar is simply the difference of passing the sugar through a granulator, which makes but very little difference indeed. It simply dries it, that is all. The raw sugar, as we sold it this year, was sold as it came from the centrifugals. That is where we threw the molasses out of the sugar. The only other process is the granulator; it passes through the granulator, where it dries it; but in making granulated sugar we have to wash it in the centrifugal, being sure to get all the color of molasses out of it, so that when it is dry it will be entirely white, while with the brown sugar we do not have to be as careful about that; but the difference in refined sugar and raw sugar, as far as the manufacture is concerned, is very little indeed.

Q. It pays, then, to be equipped for refining?—A. Certainly. We are not in the hands of the American Sugar Refining Company, or any trust, because it is only a matter of having a little belt and refining our sugar or selling it raw. It is simply a matter of business with us—which we could get the most out of.

Q. (By Mr. SMYTH.) Sugar sold unrefined is heavier? A. Heavier. It is just like very light brown sugar that used to be sold in our grocery stores, but little of it sold now; but when we can sell, it matters not whether to a trust or any other man who wants to buy our sugar at less than half a cent difference between granulated price and refined price, they will get it, if they can pay us for it.

Q. (By Mr. CLARKE.) How does your soil and climate compare with the soil and climate in the valley of the Connecticut River in New England and the White

River?—A. I think it is but very little different. You may have more stone than we have, and you can not grow beets on stony ground. You can grow it, but it is too expensive for cultivation. But your soil which is free from stone is as well adapted to it as ours. The trouble with that country is that there are not enough beet acres to the square mile; it takes in too much territory.

Q. (By Mr. A. L. HARRIS.) How many acres do you calculate will be necessary to supply your mills when you increase the capacity to 500 tons?—A. About 4,000.

Q. You mean 4,000 acres in beets each year?—A. Yes.

Q. Then, with the rest it will require, of course, an addition of acres in land?—A. Yes; ought to have at least 12,000 acres.

Q. Now, your own calculation of \$30 an acre as the cost of raising beets—that of course does not include owning the land?—A. No; I am only telling now of the labor, cost of feed, and fertilizer.

Q. What is the rental value of beet land?—A. The rental value of land in our section would be about \$10 an acre—that is, I think that land suitable for growing beets, that which ought to be put to beets, would be worth \$10 an acre to rent, if a man could rent a good deal of it at that price. I think that would be about the price.

Q. (By Mr. CONGER.) What would it be worth an acre to buy it?—A. Well, to buy it in connection with farms, you mean, or buy it separately? Our farms are all laid out. Most of them run from the river back, and it takes part of the river flats, and included in each farm is also part of a hill or upland, which is not as valuable as flat land. That land would be worth, I think, \$100 an acre—that is, the land, I mean, which would be suitable to grow beets.

Q. (By Mr. A. L. HARRIS.) To encourage that the State of New York has given a bounty. Do you think that has been necessary to encourage the enterprise?—A. It has; yes. This 500-ton plant at Lyons would not have been built if not for that. I do not think our factory would have been built if not for that. The bounty law was passed before our company was organized.

Q. (By Mr. CONGER.) Is there any limit as to time in that bounty law; in other words, does it continue indefinitely?—A. No; except this: When the bill originally passed, it provided that bounty should be paid at least 5 years. It did not limit it to 5 years, but virtually committed the legislature to 5 years' bounty, although the appropriation had to be made every year. There has been no disposition to retract from that position by the New York legislature.

Q. (By Mr. SMYTH.) What does it cost New York State in dollars and cents?—A. They appropriated this year \$50,000, and there was \$30,000 in the fund. The first year they appropriated \$25,000. Last year they appropriated, I think, \$40,000; I am not quite sure about that.

Q. (By Mr. CONGER.) Did those who supported the bounty feel that monopolies might be raised?—A. I do not think the industry should be fostered continuously. Now, my judgment is this: If the bounty in our State—you see it is to help the farmer, because we would not pay \$5 a ton for all beets if we did not receive a bounty. Now, with us the object and the intention of the bounty was to aid the farmers.

Q. (By Mr. SMYTH.) The law compels you to pay the \$5?—A. Yes; and we can not take any beets of any kind at a price less than \$5 a ton and receive our bounty. Now, where I think the bounty ought to go is to assist the farmer. If they would put competent men in the field and show him how to cultivate this crop and how to produce it at its least and minimum cost, then the industry is established in this country. Now, the factory end of it will take care of itself if the farmers will produce the beets.

Q. (By Mr. CLARKE.) Is not the State board of agriculture giving special attention to instruction of farmers in this respect?—A. Yes; our State has done nobly, and other States have done nobly in that respect; but it wants someone not only to publish pamphlets, but it wants someone to go right in the field and do just what Dr. Wiley said he was doing with the drill and show them how to use it—to put the right amount of seed in the ground; but the average farmer don't read all that is published for him to read, and he don't follow all he reads.

Q. You think it would help the State to employ men in the sugar-growing section—say, 1 man for each factory—to instruct the farmers?—A. We have 5 men in our State now. Seventy-five hundred dollars is appropriated out of this bounty fund to pay for men to go among the farmers and instruct them in our State.

Q. (By Mr. CONGER.) Do they take to that instruction kindly?—A. Yes, very kindly, indeed; and they are glad to see the man, provided he is a man who can tell them more than they already know. Now, that is the very essential part of it.

Q. (By Mr. CLARKE.) How are the men selected—by the civil-service examination?—A. They are selected by the civil-service examination.

Q. Have the selections generally been fortunate?—A. Most of them have.

Q. (By Mr. SMYTH.) Are those men at the call of the farmers? Can they invite them to come, and send for them?—A. The factory gives them a list of the growers, and they go to them and report to the State auditor at Albany and report to us.

Q. So they visit each farmer?—A. Yes. They visit him two or three times during the season. Now, the farmer will take a good deal better care of his crop if he knows somebody is going to come around to look at it, and if he knows he is brought in comparison with his neighbor it is an incentive and inducement for him to take care of that crop and have it compare favorably with others. It is one of the best things we have got. The first year we employed 4 men ourselves and kept them in the field all summer to do this work, and at the end of the first year we had a record giving the man's name, the number of acres, the post-office address, the kind of soil, the kind of fertilizer used, how applied, when applied, and analysis of the beet, and his yield, which gave us a history of every man's crop. We did not get this from the man himself, but from the man we sent to his field. That we have on record, which tells us and enables us to tell the farmer the kind of soil that will produce the best beet, the kind of cultivation best adapted, the kind of fertilizer he needs most, and we are giving him that all the time. That is our business. Now, we want the farmer to help.

Q. (By Mr. CLARKE.) Do you hold meetings in the nature of farmers' institutes and discuss the question?—A. Yes, we are doing that constantly in the winter and spring, and the man that needs the help in this matter, and must have the help to make this a success, is the farmer. The United States is going to produce its sugar. It is just a question of whether it takes it up now and goes on with this matter, or whether it is going to be some years before the farmer gets the education which he must have if he is going to grow sugar beets successfully. Now, it is just as I said, the man who produces and who is most saving to grow beets is the foreigner. The average American would rather ride, wants a cultivator or plow or something he can use that he can ride.

Now, I very much hope that the State of Michigan is not going to be any worse off on account of the number of factories she has got. I should be very sorry indeed if there were any factories there that were not going to get enough beets.

Q. (By Mr. A. L. HARRIS.) Do you think of anything further?—A. Well, I am particularly anxious to give you all the information I have, and the information from our experience in this matter, that you may be able to know exactly what to do and the wise thing to do in regard to fostering this industry, because to me, I believe there is nothing so important to the American farmer to-day; that there is no crop that is open to him; there is no business on which he can lay his hand that means as much to him as the beet-sugar industry does. I believe it will do more toward lifting up agriculture, if rightly put on its feet, than anything else. That I believe, and I believe it to the extent that I have been willing to stake a good deal on it, and I believe that it only needs just the help that I believe you are seeking to give it in order to have that accomplished. I am confident, and I am sure from the results we have already had and the experience with which we are meeting, that the farmer must have encouragement, he must have help, he must be educated in order to produce this crop at a cost that will enable him to desire to do it.

Q. Have you ever made a calculation of the number of acres of land that would go into beet culture necessary to supply the United States with sugar?—A. Yes. I do not know whether I have that correct or not, but when I was looking up the question of establishing a factory in Binghamton I went into all of those questions; in the first place, the amount of sugar we consume, and my estimate then was that it would take over a million acres of the cultivated land of the United States to produce the sugar that was necessary—that we are now consuming.

Q. That would take that number of acres then out of— A. (Interrupting). Competition of some other lines, and it would leave at home the money which we are now sending away from home, and would give employment to the people who are now asking for employment and anxious to get it.

Q. You think, then, that the farmer outside of the beet-growing belt is interested also?—A. Just as much as the one in it, because the man on the upland who has no beet land to grow, has not as many bushels of potatoes, bushels of corn, and bushels of wheat, to come in competition with; he is in better position than he is if his neighbor in the flat country could grow these products at less cost than he can grow them, and has got them to put on the market against him. Now, we have the land and an abundance of it; we have the labor; we have the soil; we have the climate, and why should not we produce our sugar beet? I know of no reasonable answer.

Q. (By Mr. CLARKE.) How far can you afford to haul beets?—A. We haul them from 75 to 100 miles.

Q. Then it would pay the farmer who has a small area of his farm, even an

acre or two, to grow that kind of beets?—A. Certainly. Now it does not mean the keeping of one less cow or the product of one less pound of butter. It does mean the producing of less products of other kinds, but here we are producing a food that goes back to supply the place of those. The consumption of sugar in this country to-day is about 80 pounds per capita and increasing every year, and three-fifths of all the sugar we are now consuming is beet sugar.

Q. Do you know how the profits of beet growing compare with the profits of tobacco culture?—A. The profits of tobacco culture for the past two years have been better than this. We have realized more per acre from tobacco than beets, because we have had that in a section where it came in direct competition; but the price of tobacco has been exceptionally high, with the exception of some few instances I know of where the crop has been entirely destroyed by hail.

Q. This condition you regard as abnormal owing to the results of the Spanish war, I suppose?—A. I do. It comes more directly in competition with cabbage and potatoes and crops of that kind, and with the grains, and the cabbage has been higher than I have known it for the last two years, and yet we have a great many acres devoted this year to beets that were formerly devoted to cabbage.

Q. Is cabbage a sure crop?—A. If plenty of fertility is applied to the soil, it is; but it is a very uncertain crop as far as the price is concerned. But here is a crop that is sold, and the price is fixed before it is planted. The farmer knows what he is going to do; he has not got to store it; he hauls it immediately from his field to the railroad or factory, and it is disposed of. What other crop is open to him with which he can do that?

Q. (By Mr. A. L. HARRIS.) How long will that condition last?—A. Well, I have no fear in my time of our being able to produce the amount of sugar we are consuming. I have not any fear of it at all. I do not believe we can do it.

(Testimony closed.)

WASHINGTON, D. C., May 16, 1900.

TESTIMONY OF MR. CLINTON D. SMITH,

Director, Agricultural Experiment Station, Lansing, Mich., and Superintendent of the Michigan Farmers' Institutes.

The commission met at 10.18 a. m., Mr. A. L. Harris presiding. Mr. Clinton D. Smith, director of the Agricultural Experiment Station, Lansing, Mich., was introduced as a witness, and, being duly sworn, testified as follows:

Q. (By Mr. CONGER.) You may state your full name and post-office address?—A. Clinton D. Smith; Agricultural College.

Q. And your occupation?—A. I am director of the experiment station and superintendent of the Michigan Farmers' institutes.

Q. How long have you held those positions?—A. I have been director of the experiment station since July, 1894, and superintendent of institutes for one year.

Q. In the performance of your duties at the agricultural college you have had considerable to do, as we understand, with the industry of raising sugar beets and in the manufacture of sugar therefrom?—A. Yes.

Q. You may, if you will, then, in your own way, state to the commission any information that you may have that may be of interest and use to us. If you have a paper, you may read that?—A. In the first place, as to my relation to the work: Having been in Nebraska at the time of the manufacture of sugar from beets had its inception at Grand Island, and having studied the matter there, as the various forces began their work to create factories in Michigan, I was called upon by the promoters of those factories to visit the places where the factories were about to be organized to give advice; and in the second place, I was called upon to talk to the farmers in regard to the method of growing beets. As stated in the paper, I made something like 50 of those addresses last spring. I also visited all the places where factories have originated in the State, as at Caro and Rochester, and talked with the people both before, at the time of, and after the contracts were let.

Q. In referring to contracts, do you mean contracts with farmers for beets or for the building of plants?—A. I refer to the contracts between the owners of plants and the people who built them. As director of the experiment station, I had also to write the bulletins, with the assistance of Dr. Kedzie, and publish them, relating to the industry in the State.

Q. You have a paper prepared?—A. Yes.

Q. You may read it.—A. I ask the privilege to modify and comment and otherwise, if the commission please.

Q. You may feel at liberty to do so. (The witness reading:)

"THE RELATION OF THE MANUFACTURE OF BEET SUGAR TO FARMERS AND THE LABORING CLASSES IN MICHIGAN.

"As early as 1890 and 1891 the experiment station of the Michigan Agricultural College had distributed sugar-beet seed, which it had imported directly from Germany, among farmers scattered well over the State. The analysis of the beets had shown that roots containing a higher per cent of sugar would be grown in all parts of the State south of the line drawn east and west through the southern boundaries of Manistee and Iosco counties. After that time and up to the beginning of 1897 there had been frequent failures in the wheat crops and in the fruit crop along the western borders of the State, two of the principal sources of income to the agriculturists. Owing to droughts and the depredation of insects the clover crop had partially or, in some sections, wholly failed. There was, for these reasons, an active demand among farmers for some new crop that should be profitable.

"The United States Department of Agriculture sent to the Michigan experiment station early in 1897 a considerable amount of beet seed, which it was my duty to judiciously distribute to still further determine the best localities for growing beets on a commercial scale. The seed was distributed, and the results of the analyses of the product of the various counties are reported on page 149 of Bulletin 150 of the Michigan experiment station, as follows:

"RESULTS BY COUNTIES.

"In order to present the results in the different sections of the State, Table II is inserted, giving the number of samples sent to the station from each county, the average per cent of sugar and coefficient of purity of all samples sent, and a corrected table in which the samples grown on the wrong kind of soil, or with poor seed, are omitted. Seed was distributed in 63 counties and from the table below it will be seen that samples have been received from 64 of them. The average per cent of sugar in the beets of the whole State, when grown on the proper kind of soil and from the right kind of seed, is 16.40, and the coefficient of purity is 84. This coefficient of purity signifies that of the whole amount of materials in solution in the sap of the beet, 84 per cent is sugar and only 16 per cent is gummy, saline, or nonsaccharine matter. An average of 16.40 per cent of sugar for the whole State, far exceeding the best districts in France and Germany, is both surprising and gratifying.

TABLE II.—Results by counties.

Counties.	Total number of samples.	Per cent of sugar in them.	Coefficient of purity.	Samples rejected for bad soil or seed.	Number of samples on right soil and proper seed.	Per cent of sugar in such samples.	Coefficient of purity.

¹ Five samples from Oceana County are not included in results of analysis because they were dried and damaged by keeping.

"Your attention is respectfully called to the history of the beets grown by Higgins & Lenders, and others in Saginaw County, in 1897, as reported on page 137 of this bulletin. You will note the high per cent of sugar and the most excellent, and occasional incredible, yield per acre, remembering that the various yields were in many cases largely estimated, though estimated from weights and measurements.

"This work in Saginaw was no inconspicuous factor in determining the location of the first factory to be erected in the State—that of the Michigan Sugar Company at Bay City, 14 miles north of Saginaw, and on Saginaw Bay."

Let me interpolate here the statement that when Mr. Cranage, the very efficient president of the Michigan Sugar Company, began the study of the question of locating a factory at Bay City, the first element in his decision was the numerous analyses of beets made by the station and reported in Bulletin 150. You will understand at the very outset that the reports of yield per acre stated in that bulletin are based upon measurements and weights it is true, but included a large element of estimation, and are therefore to be taken cum grano salis.

I have now to present to the commission a table not heretofore compiled, show-

ing the analysis of beets in the various counties of the State in the several years of 1897, 1898, and 1899. I call the attention of the commission to this because it is not in my paper, and because of the very evident and important decline in the per cent of sugar in the beets from the years 1897 to 1899, inclusive. I wish the commission to understand that this decline is more apparent than real. In the year 1897 we examined a great many samples of beets from over the State, and the beets were very carefully selected, and to the station there were sent beets of only small size and typical in shape, with the result that the analysis shows a very high per cent of sugar. In 1898 the plots were grown in areas from one-quarter of an acre to an acre, and average specimens were sent and marked, which is equally true of the product of 1899, consequently the results of these years are based upon the average specimens, while the results of 1897 were based on selected specimens. This table further demonstrates—

Q. (By Mr. CONGER interrupting.) It might be well for you to mention at this point, I think, some of the average yields per acre to which you refer in that bulletin, as we will probably not want to embody the bulletin in the testimony.

The WITNESS. The yields to which I refer are all excessive yields reported in that bulletin. For instance, a yield of 90 tons to the acre is reported, an amount so immense as to be grotesque, and let me say further, that the report of these excessive yields has done incalculable damage to the industry in the State.

Q. What, in your opinion, would be a fair statement of the average yield per acre for land devoted to raising beets in Michigan in 1898 and 1899?—A. I can not speak with any degree of positiveness about 1898 except to say that the yield was a great deal larger relatively in 1898 than 1899, for two reasons: In the first place the season was vastly more favorable, and in the second place the major part of the yields were confined to areas specially well adapted to the growing of the beets, namely, the Saginaw Valley; I judge in 1898 it was about 10 to 11 tons per acre.

Q. How much in 1899?—A. To the acres harvested the yield in 1899 was about 6 to 7 tons; of the acres sown not to exceed 4, and possibly not to exceed 4, there being a large number of acres sown in 1899 that were never harvested.

Q. The principal reasons for that were weather conditions?—A. Two principal reasons; weather conditions and the fact that beets were put upon land ill adapted to them. I refer now especially to the very sandy land, such as is found north and west of Holland and east of Caro or east of Rochester. Those are the 2 chief elements in the small yield. (Reading:)

"Beet seed was distributed again in 1898, and later in 1899, to selected farmers widely scattered over the State. In both these years the beets were grown in plots larger than a quarter of an acre each. The results of the work for the three years are given in the following table:

Counties.	1897.			1898.			1899.		
	Number of samples analyzed.	Percent of sugar in juice.	Purity.	Number of samples analyzed.	Percent of sugar in juice.	Purity.	Number of samples analyzed.	Percent of sugar in juice.	Purity.

"There has been much excitement in all parts of the State in regard to the sugar industry, and it has been my duty as director of the station to speak in practically every county south of a line drawn east and west through the south boundary of Manistee County on the question of beet raising, explaining to the farmers the soil conditions requisite, the amount of labor involved, the cost of the crops, and the possible yields. The attitude of the speaker was conservative, tending rather to quiet the excitement than to increase it. Fifty such addresses were delivered.

"It must be remembered in this connection that the agriculture of the State was depressed, and that farmers were discouraged by successive failures of wheat. So great has this depression become that agents of the Canadian government and of the great railroad companies owning lands in the United States, in the Dakotas and States adjoining, have succeeded, through the activity of shrewd and plausible (?) agents at various points in the State, in securing a large migration of agriculturists westward. There exists in Michigan to-day an organized emigration department which, by systematic work, including the distribution of literature and personal solicitation, has succeeded since the beginning of the year 1900 in securing the migration from Michigan of several hundred people, chiefly tenants and laboring men. The significance of this fact, in connection with the gradual but irrevocable western movement of the crest of the wave of maximum agricultural financial success, can not be overestimated."

The bearing of that fact upon sugar-beet raising can not be omitted. If you

please, over in Shiawassee County alone there has gone at one time one train load and at another time a considerable number of laboring men, rendering the problem of securing sufficient help a very serious one. The Canadian government maintains a general agent who has charge of special agents through the State and is securing by all sorts of representations, mostly true, I hope, the migration of Michigan citizens to the great Canadian northwest.

Q. (By Mr. A. L. HARRIS.) Does that take your best labor element?—A. Yes and no. It takes the farmers who have rented land heretofore or worked land on shares largely, and we think it has taken also the men and families who worked upon the farms. Their expenses through to the northwest are paid by the railroad, I believe, although I am not too positive upon that point, and they are put down in the northwest free of charge, a movement which we greatly deplore. (Continues reading.)

"The farmers of the State are for the most part native-born American citizens, accustomed to the growing of the cereals and not to the system of agriculture in which the application of a large amount of labor to a small area is involved; but repeated failures of accustomed crops had made them ready to welcome any new one that gave promise of adequate financial returns for labor expended upon it.

"While the surface of the State of Michigan is covered to a great depth with a glacial drift, so that areas of clay, loam, and sand succeed each other in inextricable confusion, still certain areas have well-marked soil characteristics. The broad alluvial Saginaw Valley, in which are located the 3 factories at Bay City, is undoubtedly the most promising section of the State from the standpoint of the beet grower. The water table is within a few feet of the surface. The soil, while rich in organic matter, has still an abundance of constituents. It is friable and easily penetrated by the growing roots, resembling somewhat in physical makeup water-holding capacity, and relation to the water table the valley of the Platte in Nebraska. Moreover, the area having once been the bottom of a broad lake or river, the surface is almost or quite level. Much of the land, since given over to beet growing, was formerly devoted to truck farming and gardening, lines of work which fitted both the farmer and the farm for the economical production of large crops of beets.

"Other sections of the State are found to be well adapted to the industry. Near each factory, it is true, there are many farms too sandy and light for beet production in dry years without a system of culture, not yet attained by our farmers, directed to the maintenance of a surface-soil mulch to prevent the rapid escape of moisture. Too many of these farms were injudiciously selected for beets in the dry season of 1899, with results disastrous alike to the hopes and the finances of the owners. North and west of the Holland factory is such an area, on which, last year, many hundred acres were planted, part of them thinned, and none of them harvested. These farmers are firm in the belief that beet raising does not pay, and no arguments based on statements regarding the adverse season have any weight with them. Such areas are not wanting about the Peninsular Sugar Company's factory at Caro, or about Rochester, the site of the factory belonging to the Detroit Sugar Company. About the Alma factory the soil tends rather to a clay loam with greater power to resist drought. In fact there is fortunately within reaching distance of each factory an abundance of soil that is in all respects well adapted to beets, and which will produce in all normal seasons abundant and paying quantities of roots rich in saccharine matter as soon as the farmers have learned how to prepare the ground and care for it when once sown. No existing factory can be said to be badly located as to soil, nor are all the desirable locations yet occupied.

"In selecting proper sites for the factories matters other than the attitude of the farmers and the quality of the soil had to be considered. Chief among these factors were the water supply, abundant in quantity, pure in quality; and transportation facilities, upon which depends the cheapness of coal and limestone. The nine factories in 1899 are located as follows: Three at Bay City, viz: The Michigan Sugar Company, the Bay City Sugar Company, and the West Bay City Sugar Company; the Alma Sugar Company, at Alma, 40 miles directly west of Saginaw; the Peninsular Sugar Company, at Caro, east and slightly north of Saginaw; the Detroit Sugar Company, at Rochester, Oakland County, north of Detroit; the Kalamazoo Sugar Company, at Kalamazoo, in the southern central part of the State; the Wolverine Sugar Company, at Benton Harbor, in the southwest corner of the State, and the Holland Sugar Company, at Holland, on the west coast."

There is now in process of erection a new factory at Marine City, on the extreme eastern coast of the State. The foundations were dug last week, and the process of construction is now well under way. There are also two other factories organized, but no money has yet been expended.

Q. Are these factories making contracts yet?—A. No. The Marine Sugar Company, I understand, have made some contracts, but I do not know. (Reading:)

"The great bulk of the capital required to erect, equip, maintain, and operate these immense and complex factories was supplied by Michigan men, a fact that attests both the enterprise of the citizen and his faith in the business.

"The Michigan Sugar Company, at Bay City, was the first to build a factory, their initial campaign being in 1898. They were fortunate in having, as patrons, an agricultural community composed largely of Germans and Hollanders, many of them accustomed to raising beets in their native homes. They were therefore intelligent in their methods, and were at the same time working on a soil adapted to the business. The season of 1898 was in most respects favorable, although the fall was excessively wet, making harvesting difficult, unpleasant, and expensive. The factory secured nearly its full complement of acreage, the farmers entered into the care of the crop enthusiastically, the harvest was abundant, and the financial returns to the farmer exceedingly satisfactory. I give here by way of illustration the results obtained by several farmers about the factory in 1898:

Name.	Area.	Per acre.			
		Yield.	Cost.	Receipts.	Profit.
	<i>Acres.</i>	<i>Tons.</i>			
G. Hine	24	13.1	\$11.25	\$64.59	\$23.34
S. F. Sayles	4	17.5	46.30	67.52	21.22
J. F. Boes	1	18.8	32.02	89.09	57.08
John Jones	3	14	27.48	73.33	45.83
J. McKinney	3	18	27.81	79.98	52.14
J. W. McIntosh	8	17.5	35.15	60.75	31.60
Thomas Handy	16	12	31.68	57.34	25.71
C. B. Chatfield	13	14.5	38.82	65.25	26.43
T. F. Shepard	9	12.2	25.37	53.88	28.51
F. E. Webster	19	11.4	24.60	43.45	18.85

"I cite these cases as examples of intelligent management of good soils in a favorable season."

Q. (By Mr. CLARKE.) I notice that the yield per acre, that is, the profit per acre, was larger where there was a small acreage than where there were large acreages.—A. May I explain by saying that Mr. Boes and Mr. Hine and one or two others were old German beet raisers. They had small areas which had theretofore been devoted to truck crops, and, as I know by inspection of most of these areas, they were deep rich soils in the very pink of perfection for growing beets; the season was exactly right; they knew just how to take care of them, and they got phenomenal yields which have done incalculable injury to the State, because other farmers won't realize what you and I realize, that there was an exceptionally favorable combination of circumstances. (Reading:)

"Frequent visits to the farmers about Bay City during the summer of 1898 convinced me that the community as a whole was enthusiastic in the belief that great profits were to accrue from the growing of beets."

Q. (By Mr. A. L. HARRIS.) I notice some of your best profits occur where there is the greatest cost of raising per acre.—A. Yes.

Q. That shows, then, the difference in cultivation?—A. The more intelligent the application of fertilizers and the cultivation of a good soil, the greater the yield. We expect, for instance, if our farmers the past adverse season, had had 8 or 10 years experience and information how to meet those adverse conditions, the results would not have been as disastrous as they have this past campaign, because by proper cultivation the ill effects of the drought would have been largely met. (Reading:)

"Other communities began to send committees to Bay City, and the good fortune of that factory in 1898 was without question one of the strongest inducements to both capitalists and farmers to invest money and work in sugar production in Michigan.

"It was assumed that the almost phenomenal results obtained on a peculiarly favorable soil in a peculiarly favorable season by experienced beet raisers would be duplicated on less favorable soils by inexperienced farmers regardless of the season. Farmers all over the State were aroused from apathy and indifference to unbounded and unwarranted confidence in the certainty of financial profit from this new industry. Factories were built, as indicated above, and little difficulty was experienced in securing sufficient acreage.

"Another and possibly the chief factor in bringing about the construction of these factories was the promise of bounty made by the legislature in an act approved March 26, 1897. This bounty was to be 1 cent per pound to the fac-

tories for all sugar made from beets grown in the State for which the factory should have paid \$4 per ton for beets containing 12 per cent of sugar, with an addition of 33½ cents per ton for each additional per cent of sugar in the beets. It may be remarked in passing that this bounty was paid to January 1, 1890, to the Michigan Sugar Company for sugar made up to that time. None has been paid since.

"I submit in the table below some of the facts in the campaign of the factories in 1899."

I call the attention of the committee to the fact that when they compare this statement with that made by Mr. Rogers yesterday, they must remember this is the per cent of dry granulated sugar and not the per cent of raw brown sugar to which he referred. The relation between the dry granulated and the brown, I do not know; that is, how many pounds of brown sugar it takes to make 10 or 100 pounds of granulated sugar. I confess my ignorance. I do not know. (Table above referred to follows:)

Name.	Net tons of beets sliced.	Pounds of sugar produced.	Pounds of sugar per ton of beets.	Pounds of sugar per 100 pounds of beets.
Michigan Sugar Co	40, 720	7, 415, 233	182.1	9.1
Bay City Sugar Co	40, 084	6, 942, 000	169.2	8.46
West Bay City Sugar Co	17, 334	2, 162, 157	124.0	6.2
Peninsular Sugar Co	25, 581	4, 004, 884	155.9	7.94
Detroit Sugar Co	21, 064	3, 669, 839	169.4	8.47
Wolverine Sugar Co	10, 797	1, 787, 233	165.5	8.27
Holland Sugar Co	16, 871	2, 585, 779	153.1	7.66
Kalamazoo Sugar Co	9, 681	1, 441, 998	147.7	7.38
Alma Sugar Co	19, 700	3, 359, 366	167.0	8.3

(Reading:) "The reports of the factories for the campaign are not yet complete. The weight of sugar manufactured is correct. The net weight of beets is approximately so, making the sugar per ton of beets as given very nearly correct.

"As to the quality, first, of the sugar made, I am glad to say that it was generally a prime article. It must be admitted, however, that certain factories were, by reason of machinery not adapted to American conditions, unable to make a first-class article, and as a result the reputation of Michigan sugar in the markets is somewhat injured."

The commission may be aware that there is a lawsuit now in the courts between the Peninsular Sugar Company at Caro and the contractors that built the factory. These contractors put in entirely German machinery. The owners did not know what they wanted, and the contractors did not know what was wanted, and the contractors therefore put in machinery that was adapted to the manufacture of sugar for refining purposes and not sugar for the market. The Caro factory is under the very efficient management of a president who is a thorough business man, and he succeeded in selling that sugar to the refining companies and elsewhere at very good advantage, so that the financial loss during the past season was not so great. Unfortunately, much sugar was sent to Chicago that ought not to have gone there, and I saw there in the hands of factors barre's of sugar offered as typical of Michigan beet sugar, where the barrel was stratified light blue, yellow, white—light blue, for instance. The people who formerly had bought the product of the Michigan sugar companies without question, asking no further certificate than the fact that it was made by the Michigan beet-sugar factories, became at once suspicious and would buy no sugar from Michigan without examination. That matter, however, was stopped, and I hope the damage has not been great.

Q. (By Mr. CONGER.) Your idea, then, is that the reputation of the product of the Michigan factories suffered from the output of this one factory?—A. Yes. I stayed in Chicago for a short time, long enough to make an investigation, and I know that to be the fact.

Q. Have the proprietors of these other factories suffered in the way of being unable to sell their products at so high a price as formerly?—A. No; they at once notified their factories and stopped the damage just as quickly as they could.

I might say that the product—as an instance—of the Benton Harbor factory, the Wolverine Sugar Company, sells rather above, I think about ½ cent above the market for average goods because of its pearly whiteness and fine even grain. That was sold in Grand Rapids and in Chicago. The same thing is true of the Michigan Sugar Company; and in fact I ought not to mention one company except by way of illustration and not to draw an invidious comparison to the others in Michigan

I might say, also, that the West Bay City Sugar Company has brought suit, or is to bring suit—I am not certain which—against the construction company because the beets yielded only 124 pounds of sugar per ton of beets. Now, they had to pay an average of \$4.33½ a ton for these beets, and receiving only 124 pounds of sugar to the ton of beets, under the market price of sugar, they suffered great financial loss by reason of the German machinery put in that factory not being capable of extracting from the beets the amount of sugar it ought.

Q. You say they averaged \$4.33½ for their beets. That price was determined by the purity of the beets; by the sweetness of the beets?—A. Yes.

Q. By test?—A. Yes.

Q. What would that price of \$4.33½ indicate as to the sweetness of the beets?—A. It would be just 13 per cent average.

Q. And this record you have just read of 124 pounds of sugar to the ton would indicate something very different, would it; that there was some trouble?—A. The construction companies say that their factories ought to take out 10 per cent of the sugar—that is, they ought to get 200 pounds of sugar. A ton of beets weighs 2,000 pounds, and at 13 per cent there would be 260 pounds of sugar in the ton, and they ought to get 200 pounds out. As a matter of fact, I have never been in any factory east of California that made any claim to get out as much as that, and our factories, as the table I have just read shows, come very far short. The old Michigan Sugar Company gets out, as you see, 183 pounds, but as I have heard, until they got a letter from Dr. Wiley they got out much less. You see the season was peculiar, and the per cent of nonsugars was high, and they had to modify the temperature in their diffusion batteries in a way that these German operators did not know anything about. As a result the Michigan sugar factories will be manned by Americans next year almost exclusively.

Q. Has it been the custom among the factories there in Michigan to employ Germans as superintendents?—A. Had to. You see it requires a high degree of skill to manage a factory from the diffusion battery to the sale of the sugar, and that skill is acquired by experience only, and as a result—if I may state a specific instance without making reference to any other factory—the West Bay City factory has imported Bohemians and Austrians to manage their factory.

Q. What number?—A. I think about 125. They were shipped back to Bohemia with the thanks and good wishes of the factory immediately at the close of the campaign, and next year they will be replaced almost entirely by American laborers who can adapt themselves more readily to the new conditions obtaining in this country.

Q. In other words, the employment of those foreigners has not been entirely satisfactory, either as laborers or as superintendents?—A. No; it has not been. Understand, that does not refer to the chief superintendent. The superintendent, if I may enter into personalities—I do not know how far I should do so, but I depend on you to check me—the superintendent of the Michigan Sugar Company is a man by the name of Brysselbout. He is an exceedingly efficient man, and the success of the factory is largely due to his efficiency. The superintendent of the Bay City factory is a foreigner, but an exceedingly efficient one. The same is true of various other factories; but understand that under the superintendent there are men who superintend or control the treatment of the diffusion juices, and then the strike pan and the management of the limekiln and the various departments of the factory. They have universally been foreigners in our State during the campaigns of 1898 and 1899, and it is to them that I refer when I say that they are to be replaced by Americans. All who have charge of divisions and who receive good salaries and on whom rest responsibilities will, in the main, be Americans in Michigan. (Reading:)

"Taking up the factories one by one, permit me to report certain details. The campaign of 1899 was the second one for the Michigan Sugar Company, which had sliced during 1898 over 41,000 tons of beets, and had made therefrom 5,280,000 pounds of sugar. Its second campaign was marked by the fact that the experience of the year preceding, with the opportunity to improve machinery during the summer of 1899, has resulted in a campaign practically without accident or stoppage. The second campaign lasted 114 days. There are 190 men employed in and about the factory, 20 men working the entire year. The quality of the sugar is uniformly first-class. The factory was built by Fred W. Wolf Company, Chicago. They have 4,000 acres contracted for the coming campaign. The men employed are for the most part American born, and nearly all of them American citizens. The per cent of marc used in converting per cent of sugar in juice to sugar in beets was 5. The factory has a nominal capacity of 350 tons a day, although it has sliced as high as 400 tons per day for several consecutive days.

"The Bay City factory has a capacity of 500 tons per day, with room for double that amount, and cost \$500,000. The sugar produced is excellent in quality, and

is sold in Chicago very largely, some going to Michigan points. No dividend has been declared this year, the profits made being applied to retiring bonds and the betterment of the plant. Both these factories use limestone from Trenton and Wyandotte quarries. The factory was built by the Kilby Manufacturing Company, of Cleveland, and is giving good satisfaction. It was in operation 110 days during the last campaign. There are employed in and about the factory 250 men, 30 of whom work the entire season, and 30 more during June, July, and August in repairs and preparations for the coming campaign. The owners are at present installing a plant for drying the pulp and mixing with molasses, making a feed for cattle, which will be put upon the market, the bulk of it being already sold for export at a nominal advance over the cost of production. This dried pulp contains less than 10 per cent of water; it also contains 16.90 per cent of protein, as analyzed by the chemists of the factory, with a high per cent of carbohydrates. The per cent of marc used averaged 8. The factory now has 5,410 acres contracted for the campaign of 1900.

"The factory of the West Bay City Sugar Company was not finished in time to begin operations until nearly the beginning of the new year. Its campaign was therefore necessarily short, and was unfortunately attended by several accidents, which seriously interrupted the work. As shown in the table above, but 124 pounds of sugar were manufactured from a ton of beets. This small yield made the factory owners somewhat dissatisfied with the plant, and they have refused to accept it from the builders. Owing to the lateness of the start in the last campaign, many of the farmers that had contracted with the factory sought relief from their contracts and delivered their beets to other factories. As a result, this factory has few contracts for 1900, the total acreage to date being scarcely more than 2,000. It must be confessed that the location of 3 factories within 1 mile of each other was a hazardous undertaking. Had the community been thoroughly accustomed to growing beets, it would have been much less so. The inevitable consequences of this proximity have already manifested themselves, since the available acreage at this stage of the history of the industry is unavoidably limited.

"The Peninsular Sugar Company has located its plant at Caro, some 26 miles east and north of Saginaw. The building is a large one and is fitted with machinery to consume 500 tons of beets per day, with opportunity to double its capacity. The factory is equipped with German machinery, and the product has not been satisfactory as to quality, the sugar being off in color and grain. As a result, a lawsuit is already begun by the owners against the contractors who put up the factory. The good will of the farmers toward the factory was manifested by the fact that there are already subscribed for next campaign pledges for nearly 5,000 acres.

"The factory of the Alma Sugar Company is located about 40 miles almost directly west from Saginaw, in the center of a rich, populous, and prosperous agricultural community. Like the other factories of the State, it is backed by sufficient capital to insure success, if success be possible. The factory cost \$450,000 and employs 500 men, mainly Americans, and will employ practically all Americans hereafter. As the table shows, it had a fairly successful campaign in 1899, making 167 pounds of sugar to the ton of beets. In converting the per cent of sugar in the juice to that in the beets a factor of 92 was used, allowing for 8 per cent marc. There are already pledged 3,500 acres for the coming campaign, as against 3,000 for last year."

I stop to inquire whether the commission is informed as to the meaning of the "per cent of marc?" You will note that the Michigan Sugar Company use 5 per cent, this Alma Company 8 per cent, the Bay City Company 8 per cent, and some of the factories in the western part of the State using as high as—in specific cases, in dealing with individual farmers—from 10 to 12 per cent.

Mr. CONGER. The matter was given considerable attention by Professor Kedzie. We understand this marc is the percentage that the factories deduct in making settlements with the farmers, and of course it is of vital interest to the farmers. The matter has been gone into to a considerable extent.

Q. (By Mr. A. L. HARRIS.) But it may be that you have something to offer in a practical way.—A. I simply found a great deal of dissatisfaction among the individuals about Holland and Benton Harbor, because these factories have used a higher per cent of marc than the farmers thought just.

Q. (By Mr. CONGER.) These factories charge a higher per cent for marc than the factories in the eastern part of the State, as a rule?—A. As a rule. Their average may not be higher, but there are specific cases when it went exceedingly high, and that caused dissatisfaction. Some farmers absolutely refused to raise beets, because they said they had been gulled by the factory.

Q. (By Mr. A. L. HARRIS.) Does the locality have anything to do with the fixing of the marc?—A. I have no specific information on that point. Dr. Wiley or Dr. Kedzie is incalculably better informed than I.

Q. (By Mr. CONGER.) If these factories made exceptional cases and insisted on a greater allowance for marc than any of the others, were there any special reasons for it? Did they claim that the beets of the farmers in question should be charged that marc?—A. Most of the factories accepted the dictum of the Department of Agriculture at Washington, backed up by the experience of Dr. Kedzie at our own station, that 5 per cent of marc was about the normal, and they made no further examinations. Now, for reasons into which I can not enter, some of the factories in the western part of the State thought it advisable to determine the marc for themselves. I am not informed as to the reasons why that decision was made. (Reading:)

"The Detroit Sugar Company has located its plant at Rochester, not far distant from Detroit, with which it is connected by electric cars as well as by steam railroads. This factory made a relatively short run in 1899, but turned out a quality of sugar that is unsurpassed and secured a larger per cent of sugar per ton of beets than any other factory in the State except the Michigan Sugar Company.

"The Wolverine Sugar Company is located at Benton Harbor, in the extreme southwestern part of the State. Here the factory has to compete with the fruit growing in the best fruit section of the State, and also with the raising of cucumbers and vegetables for large canning and pickling factories at Benton Harbor and St. Joseph. As a result of this competition, the factory has secured its acreage for this year very largely from Indiana. There are 5,000 acres now pledged for the coming campaign. The factory was put up by E. H. Dyer & Co., and cost approximately \$300,000. Its work has been eminently satisfactory during the past campaign, the sugar being faultless and in demand both in Michigan cities and in Chicago.

"The Holland Sugar Company, at Holland, differs in some respects from the other companies of the State. A large share of the stock is owned by farmers in the vicinity of Holland, who therefore are interested in the factory as well as in the growing of beets. Last year the campaign lasted 55 days. The sugar made was excellent in quality and met with a ready sale at highest market prices. The per cent of marc as determined at the factory varied from 8 to 12.

"The Kalamazoo Sugar Company began their campaign late at their factory, north of Kalamazoo. The run was short and the supply of beets limited. The factory has pledged for next year, however, 5,400 acres, of which 2,200 acres are in Indiana and 1,000 acres in Ohio. A series of accidents delayed the beginning of the campaign last fall, but the work was satisfactory when once operations fully began. The factory was erected by F. W. Wolf & Co., and cost \$400,000."

Q. (By Mr. CLARKE.) About how far from that factory are these Indiana and Ohio plantations?—A. If you mean to ask me in miles, I certainly could not give it. I should judge in this particular case 45 miles on an average.

Q. (By Mr. CONGER.) Is it not farther than 45 miles from Kalamazoo to the Indiana line?—A. I do not know. It is a matter easily ascertainable. Let me stop right here to say that the attitude of the average farmer toward the factory in Michigan is extremely reluctant—I could not say hostile; it is an attitude of waiting to see, like Micawber, what is going to turn up. The Kalamazoo factory proves the case to my mind. These people found it almost impossible to secure any acreage in territory that supplied them last year, and this territory which is to supply them this year is utterly new territory—territory on which they did not draw last year. The same thing holds true, I am informed by one of the Detroit Sugar Company men, about Rochester. They drew largely last year from west of Rochester, about Pontiac, and in the section from over Richmond way, but this year they have to work a new territory.

Q. (By Mr. A. L. HARRIS.) What is the cause of that change of locality?—A. The extremely unfavorable season last year. You may know that about Benton Harbor there are a great many hundred acres on which in May and June last year the farmer had sowed his seed originally and had waited. The seed was a relatively poor quality; the beets came up spindling, and then came the drought and they died. They resowed, but these beets were in so late that the harvest was very small. I would be perfectly safe in saying that the result, from this reason, would not average 3 tons to the acre. But you see the farmers did not know what to do, and when they applied to me I had to confess that I could not advise them, for I had never seen such a condition of affairs; so they did the best they could and resowed, and that was a mistake, as they got their beets in so late. About the other factories the same conditions obtained, and the average crop for acres harvested would not be more than 6½ tons, and for acres sown it would be very much less. I made a special effort to get for the commission definite data as to the relation between the total tons of beets harvested and total acreage sown, but I found it absolutely impossible to get data that I could swear by.

Q. You have hopes that the confidence of the farmer will be restored?—A. We are hoping and praying for a good season this year. If we get it, our farmers, like a flock of sheep, will drift over the other way. (Reading:)

"The influence of the establishment of factories upon the agriculture of Michigan is very important. In the first place, in the immediate vicinity of the factory and near all railroad stations within 40 miles of the factory it has appreciably increased the selling price of the farms."

There is a statement that I want to qualify. That statement I find not to be true about Rochester. You will understand that in getting this data I have visited and stayed some length of time near all of the factories except Caro and Rochester. I need not state the reasons why my visits there were curtailed. I have talked to a host of moneyed men and farmers in Bay City and Benton Harbor, at Holland, at Kalamazoo, and at Alma, names that I can give you later if you want them, that concur in the statement that the value of real estate in proximity to the factory and points located by railroad connections conveniently accessible thereto—they have increased the value of renting power and of real estate. (Reading:)

"At Bay City there is now a greater activity in real estate transfers than has been witnessed in many years, and vacant houses in and about the city are very scarce. Farms have sold at a price per acre far in advance of offers of five years ago. A host of conversations with leading business men and with farmers about Bay City leads me to believe that the net advance in real estate values, due to the establishment of the factories, can not be less than 15 per cent, while cases are on record where specific farms have been sold at an advance, in one case of 25 per cent, and in another, a very large farm, of nearly 50 per cent."

Note that these farms were sold for the specific purpose of growing beets. (Reading:)

"Land rents for growing beets at from \$5 to \$8 per acre. About the other factories in the State the same appreciation of values in real estate is notable. About Holland, for instance, the rent of land for growing beets had gone from \$6 per acre per annum to \$8, \$10, and, where the land was especially well located and of good quality, to as high as \$12 and \$15 per acre.

"At Holland there are canning factories and pickling works, which compete with sugar beets and draw heavily upon the supplies of transient labor. I visited Kalamazoo and the other localities where factories were established and find that this rise in the price of real estate has in every case followed the erection of the factory.

"In the second place, the by-products of the factory are gradually being used for feeding live stock and for fertilizers. In Bay City the supply is so large that as yet but a small per cent is thus utilized. Near that city, however, I may cite the enterprise of Mr. W. A. Wilder, who fed last year several carloads of pulp to his dairy cows and to young stock which he was wintering. The young stock were fed nothing but pulp, straw, and hay. They had no grain. They are now in fair condition, ready to turn on grass. His dairy cattle received corn, silage, hay, grain, and beet pulp. The steers ate $1\frac{1}{2}$ bushels per day of the pulp, while the supply to dairy cows was limited to less than 1 bushel per day. I found a growing feeling among the farmers in the vicinity of Bay City in favor of the pulp, and many teams were engaged up to late this spring in hauling it away. I found a farmer west of Kalamazoo, also, who was feeding 236 head of steers on pulp and hay. He had fed several carloads, and deems it impossible that the material shall not come into immediate and extensive use among cattle owners near the factories. I can cite you to many other cases where the pulp is fed extensively, and to still others where farmers are preparing to ensilage it next year, expecting to rely upon it largely as succulent feed for dairy cows and pigs.

"The slaked lime is being used as fertilizer on lands that need it near all the factories. Unfortunately the molasses, rich as it is in potash, is at present in Michigan entirely wasted.

"So far, from the very nature of things, no American seed has been used on a commercial scale by our factories. The imported seed in 1890 was in some cases very unsatisfactory. The repeated tests we have made of the seed coming into the State this year shows it to be of a very much better quality. A systematic effort will be made this year to begin the growing of seed. This industry will employ a great many men and will demand the highest type of talent to insure success.

"While at the outset it was necessary to employ experts in the various divisions of the factory work, and these experts had to be brought in from without the boundaries of the State, and even from without the boundaries of the United States, I am glad to report that Americans are rapidly learning the business, and

it will not be many campaigns before the American factories will be manned throughout by Americans.

"The establishment of the factories has exerted a marked influence on the labor market. Employment has been given to men, women, and children who would otherwise have been idle. During the months of June and July, and again in October, the factories have given rise to an active demand for persons possibly not strong enough to do the hard work of a farm, but able to do light work—to thin, hoe, and harvest the beets. Near most of the factories the supply of such labor has not been sufficient. In the campaign of the Michigan Sugar Company in 1898 beet raisers found it possible to hire women at from 50 to 65 cents per day to thin beets. Later in the season, as the labor supply proved inadequate, these same women, and children as well, asked and received from 75 cents to \$1 per day. In 1899 about the same city they have received habitually \$1 per day and dinner. The prices for this class of labor have varied from time to time and in different localities. About Benton Harbor the price per day rose to \$1.25 and board, and about all the factories in the very busy season the daily wages rapidly rose to \$1 per day and upward. I know of but one case where laborers were brought into the locality from a distance for the express purpose of doing the thinning and hoeing. This was at Alma, where a lot of men were brought from the city of Detroit to aid in thinning the beets, which, by reason of the extreme wetness of the season, had been too long neglected. The men were unaccustomed to field work and disappeared at the first opportunity.

"In brief, then, it may be stated that the introduction of the factories has increased the demand for labor and its value in the market. It has furnished employment to a large number of boys that would otherwise have been idlers, and to a possibly still larger number of women, who were sorely in need of the money thus earned. Fortunately the thinning and hoeing comes for the most part after the close of the common schools, and the topping is over soon after the beginning of the school in the fall. Thus the work interferes but little with the school attendance of the children.

"The busy period of thinning and hoeing lasts about 40 days; begins in early June, and the harvest, beginning in September, lasts well into November, the lifting and topping occurring in September and October, and the hauling to the factory continuing through to January and even later.

"The plan of furnishing employment during the summer in the fields to the men engaged in the factory in the late fall and winter will be tried this season by one factory.

"My investigations at all the factories convince me that the establishment of this industry has so far resulted in no serious disturbance of economic conditions relating to the labor market. There have been times near all factories when labor has been scarce and exceptionally high prices have been paid. On the whole, however, there has been a fair supply to meet the active demand. Mature laboring men have found remunerative employment, and the congestion of labor in the cities noted in former years has been less conspicuous this year than heretofore. I believe the work of the sugar factories has been one contributing cause to this healthy economic condition.

"This demand for labor is fairly certain to be permanent, as it seems hardly possible that any machine can be invented that can take the place of the human hand and eye in the operation of thinning, while to thin an acre of beets planted in rows 18 inches apart will require the work of an active boy or woman fully 6 days."

You will remember an acre of beets is 160 rods long if it is only a rod wide. Now, a rod wide, divided into rows 18 inches apart, provides room for 11 rows. Eleven rows a half mile long is one row $5\frac{1}{2}$ miles long, and for a boy or woman to get down on the knees and creep $5\frac{1}{2}$ miles is a rather onerous undertaking, and requires a good deal of time. Our experience, based on the raising of 6 to 8 or 10 acres at the college, and keeping careful note of the time, and getting the men whose names I read in the former table to watch matters closely, leads me to make the statement that it will require about 6 days to thin an acre if the boy or woman creep $5\frac{1}{2}$ miles; and that statement is based on the supposition that the rows are 18 inches apart.

Q. (By Mr. CONGER.) Would not one of these boys or women take two rows, and thus be obliged to creep only one-half the distance?—A. It is done that way in some cases, but it does not lessen the time materially to do that. They have got to take hold of one beet in the bunch and pull out the others. Where the wet season delays the thinning, as it did about some of the factories last year until the beets were the size of my pen and up to the size of one of these small bottles—from a quarter to three-eighths of an inch in diameter—the time required for

thinning was very much lengthened, because, as Mr. Rogers so ably explained yesterday, the roots of nearly all had grown so fast to the other beets that they found it almost impossible to pull up the beets not wanted and leave in good condition the beets they wanted to stay in the bunch. Thinning must therefore be done at just about the right time or it costs more than it should. That is why we have such an active demand for boys and women at just the one season, and again at just the exact season when we come to harvest them. That is why these women about Bay City adopted the American custom, Polish women as they were, and when they saw the supply was limited they formed a combination, got a corner on the market, and raised the price.

Q. (By Mr. CLARKE.) Why can not seeds be so perfected that each one is sure to produce a beet, and then sown so that thinning will not be necessary?—A. Unfortunately we have it so arranged that 1 seed will produce 1 beet, but they are so ambitious that they usually produce 4. The trouble is, what we sow is not the seed but the fruit, and the fruit contains 1 to 4 seeds. There are therefore liable to be 4 plants from 1 fruit. Very many factories have invented tools that drop the beet seeds at the distance apart that we want the plant, and there will be 2 to 4 plants then growing from each fruit, and thinning is, in my estimation, absolutely unavoidable; and where farmers have reduced the number of pounds of beet seed per acre, as Mr. Rogers said yesterday, they have a poor stand; and the trouble in Michigan is just as it is in New York, we can not get a good stand. Professor Wheeler, of our station, tested nearly all the beet seed sown in Michigan this year. Now, the Magdeburg rules require that 100 fruits send up, I think it is, 173 plants in 14 days. We find that the seed instead of germinating together will come up irregularly. The largest per cent will be out of the ground in about 10 to 12 days, and all of them should be out in 2 weeks. Then, again, there will be out of every 100 perhaps 16 fruits that will not germinate a plant, and the others will germinate. In fact, we may say that out of 100 beet seeds of a certain variety I have in mind, 2 weeks ago at our station there were 227 plants grown from the 100 fruits. Now, don't you see that since 1 fruit will send up 4 distinct, separate plants, thinning is absolutely unavoidable?

Q. Can these fruits be separated so that each fruit will send up only one?—A. Yes; we grind them. We break them up into separate seeds. We soak them, and by maceration in cold water, to save injuring the seed, we get the seed out separately. But they do not seem to develop well except in the matrix of the fruit itself. We were anxious as a station to aid in lessening the cost of thinning, which is the great bugbear in the eyes of the farmer, and we resorted to all sorts of experiments to find some way to avoid thinning, so far with absolutely no success. I can not report 1 inch of progress since 2 years ago, except where the farmers will consent to sow 18 pounds of seed to the acre and get a very thick stand. We do run a cultivator across the rows and do the bunching, as it is called, but even then I am advising the farmers to resort to the hoe. They do it somehow very much more efficiently. The cultivator will cut out a bunch of beets and will leave spaces where no beets are growing, whereas the man with the hoe, notwithstanding Edwin Markham to the contrary—"the man with the hoe" will leave the spaces where beets should grow.

Turning now to the farmer's side of the question, we come to the matter of the cost of production. We have raised many acres on the college farm, and I have visited repeatedly every beet-growing section of the State. By the cooperation of a large number of intelligent beet growers I am able to give approximately the average cost of growing beets in the State at large. Here are the items, some of them estimated, it is true, but all of them based on actual and extended experience:

	Cost per acre.
Plowing, usually subsoiling	\$2.50
Harrowing, several times	1.00
Seed	2.50
Sowing50
Cultivating, six times	2.40
Thinning and weeding and hoeing	8.00
Pulling and piling	6.00
Topping	6.00
Drawing, average 2.5 miles	6.00
Freight, 17 tons, at 20 cents	3.40
Unloading	1.13
Total	35.43

Two bugbears stand in the eyes of the farmer: First, it costs so much to thin and harvest; and, second, the beet crop is so exhaustive to the soil. I explain to them what Dr. Wiley and Dr. Kedzie have told us about the nonremoval of plant food itself, but the farmer says: "Remember that you told us at the institutes that where land was very rich in organic matter and in mineral plant food, and was left bare through the winter, the rains of winter and the rapid oxidation of the plant food in the soil took more plant food from the acre than three or four or possibly a half dozen crops; and consequently we must not leave our ground bare during the winter, this being especially true of the loams of a sandy character." So we are urging these farmers to subsoil early in the fall, plow the ground and fit it well and sow some crop—rye or oats—which shuts in the soil, preventing the leaching during the winter and the rainy season during the fall and spring. This crop is then inverted in the spring reploting, the ground fitted in perfect condition, and the seed sown. That is why I have put the plowing and harrowing at amounts which, to some of you who are acquainted with agricultural conditions, might seem exorbitant—\$2.50 for plowing and \$1 for harrowing an acre. It seems to be a large amount, but the success of the crop depends so primarily on the condition of the ground when the seed is sown that we insist on the farmers having confidence enough in the crop to thoroughly prepare the ground. Seed at \$2.50 per acre is not excessive, nor is sowing at 50 cents an acre, nor cultivating 6 times at \$2.40, nor thinning and weeding and hoeing at \$8 an acre. That takes us up to the time of harvest. Now, the harvesting is done in Michigan largely with the lifter, which has 2 prongs sent astride the beet some 6 or 8 inches below the surface, inclined from in front back and upward, so that it just lifts the root and breaks it as Mr. Rogers told you yesterday. The beet stands in the soil vertical, just as it stands when growing, except it is separated at the bottom. A woman or man comes along, takes hold of the beets, knocks the dirt off, and throws them into a long pile, the tops to the right. Now, there are various methods of doing that. Sometimes they are thrown in large piles and sometimes they are thrown in a continuous row, and then a person takes each beet in the left hand, chops off the top with the right hand, and throws them into a pile. That harvesting is the second large item, in my estimation, in the cost of growing an acre of beets—pulling and piling, \$6; topping, \$6.

Q. (By Mr. HARRIS.) You speak of throwing the beet. Does it hurt it or bruise it?—A. They do not throw it far enough to injure it.

Q. (By Mr. CLARKE.) Has any machine been brought in use for chopping?—A. Yes. If our beets could all be grown on land that is dead level, absolutely free from stone, and if the little fellows would only grow out of the ground the same height and stay down the same depth, that would work splendidly.

Q. Do you have a machine to top after pulling?—A. Such machines may be in operation. I do not know of any machine except the human hand so far. Some of these machines have been tried in Michigan, but all have been replaced.

The next item of large expenditure is drawing. Now, let us suppose an acre turns out 10 tons of beets (this estimate from now on is made on 17 tons to the acre, but let us suppose it is only 10 tons). Freezing does not ruin a beet, it is true, but freezing and thawing does. To haul beets for the use of the factory and deliver them in January and early February requires that the beet be pitted, as it is called. The roads in Michigan, to put it mildly, are universally bad in the fall, and the average load—I have watched them, for instance, at the Alma factory, when the average load did not come up to 2 tons. Now, supposing a man has to haul these beets 3 miles and only makes one trip a day, it takes him nearly 5 days to deliver an acre of beets. On the good roads up about Bay City I saw three-horse teams haul 3 and 4 and 5 tons of beets at a load; but the roads radiating from the factory at Bay City are stone roads built at large expense, and there the cost of delivering is very materially reduced; but about the other factories that had not the advantages of these stone roads, the cost of the delivery of the beets to the factory is a large item. If a man has 6 or 8 or 10 acres, that item of delivery is one he has to take largely into calculation.

Q. Why should not the factories have storage facilities so they can receive the beets when the roads are good?—A. I have had that brought up at every beet meeting in the State. You are asking a great deal of the factory. If it was simply a question of storage it would be hard to answer. When you store 40,000 or 50,000 or 60,000 tons, it goes up into the millions of bushels because a bushel of beets only weighs 50 pounds, and that would be 40 bushels to the ton. That would be a large proposition, but when you have to store them in such a way that the stream of water must wash them into the factory and have to store them so they will not freeze or thaw, it is too big a problem for our Michigan factories to undertake. The Benton Harbor factory is going to try it this year and the others are going to stay back and watch the proceedings at Benton Harbor. If they succeed the other

factories will hereafter undertake to store the beets and avoid the large expense of pitting.

There is another element: I find that most farmers would rather hold their beets and deliver them later. During harvest they have a large gang of men and they want to put in all their energies in getting the beets pulled up and pitted, and then along during the winter they will haul them at their leisure.

Q. You want to encourage good roads, then, in Michigan?—A. Yes; I will speak of that in time.

Now, the unloading costs on an average—I got this data from 6 factories—of about \$1.13 an acre, making the total cost, without fertilizer or rent of land, \$35.43. (Continues reading:)

"This is, of course, an average, with all the imperfections that that term implies, and does not take into account the rent of land and the cost of fertilizing. It gives a rough estimate, however, of the actual cost to the farmer, and leaves for him the question whether the resulting crop will be sufficient to give him a profit over this cost.

"The profit is contingent on the season, as well as upon the soil and the skill of the farmer. The season of 1899 was distinctly adverse; the spring was late and very wet through May and early June. The temperature for the same period was below the normal. As a result, the early-sown beet seed did not germinate and resowing was deemed necessary. The wet May was succeeded by a dry and very hot late June, July, and August. (See page 103 in Bulletin 179 of the Michigan Experiment Station.) As a result the crop over the State was well-nigh a failure. On all the sandy lands the crop was practically a total failure. On the light loams it was better, on the clay loams still better, and on the alluvial soils tending toward muck it was best of all. Notwithstanding the adverse season, some farmers harvested as high as 18 to 20 tons per acre and made a fair profit. On the other hand, other farmers lost practically all the time and money spent on the crop. Some of the farmers sowed the seed on well-prepared land, thinned the beets, and then abandoned the fields; others carried their crop through the season to the harvest, but to meet serious loss and grave disappointment. A recent visit to beet growers in the various sections of the State, and to the factories where the beets were delivered, makes me positive that the average yield for the State of acres harvested did not exceed 7 tons. I question whether it exceeded 6."

I went to a farmer, who had been renting, and asked him, "How much do you get for your farm?" "Well, sir, I am getting \$8 an acre." "What did your farm used to rent for?" "Well, I sometimes got \$6 an acre." "Has the factory increased the rental value of the farm?" "Yes; next year I won't rent for less than \$10." I went to another farmer. "How much rent are you getting for land?" "Twelve dollars an acre this year." "What is going to be done with it?" "Raising beets." It is upon these facts that I base statements which I have made in this paper, and it is upon these facts I base this statement at the present. There is a tendency to rent fields for cash rent to men who know more about beet growing than the owners do and are willing to take chances. That is especially true at Holland, Benton Harbor, and somewhat so at Bay City. (Continued reading:)

"In sandy localities many acres were plowed up without loss further than the seed, as the fields were utilized for other crops. This failure by reason of the adverse season has made the farmers hesitate about raising beets this year, and has covered the whole proposition with a cloud. The resulting attitude of the farmers, as a class, while not hostile; is not encouraging, and the factories are finding it difficult to secure sufficient acreage for a full campaign next fall.

"A second result of the adverse season has been a pressure upon the factories for a higher price for the beets and for other concessions. To this pressure the factories have yielded. The price this season will be \$4.50 per ton for 12 per cent beets, with an addition of 33½ cents for each per cent of sugar in the beets over 12. Some factories are paying the freight on the beets to the factory. In some cases the beets are unloaded free of cost, and in others the beets are received at any time and the farmers are not forced to pit them, with all the labor and cost attendant upon that operation.

"One cause of unpleasant feeling on the part of the farmer toward the factory has been the high per cent of marc sometimes claimed. The belief is nearly universal that 5 per cent is the normal amount of marc in the beet. Some factories have used figures in excess of 10, thus reducing the price of the beet very materially.

"The beet growers about Bay City have organized an association for mutual instruction in the art of growing beets economically, and for the further purpose of securing better prices for their product. The association was formed in the late summer of 1899, and has held frequent meetings through the winter and early spring. I can not give the present actual membership, but am confident that over 50 per cent of the growers tributary to the 3 factories are affiliated with it.

"It was this organization which by conferences with the factory managers secured the rise in the price of beets from \$4 per ton of 13 per cent beets to \$4.50. Similar organizations are formed at Kalamazoo for the western part of the State.

"In some of the factories the growers will nominate the tare men and possibly have some voice in the selection of the weigh man and beet tester, thus entirely removing all grounds for suspicion except in the single factor of determining marc.

"The work of this association can not fail to be of some educational value to its members, and it is education of which the growers stand most in need. The growing of beets demands far more careful methods of husbandry than those to which our farmers have been accustomed. It requires better cultivation, better fertilization, and expenditure of more money per acre. It thus broadens the mind and the methods of the farmers.

"As stated, the beet growers about Bay City, in 1898, found the crop very profitable. The cost was excessive because of inexperience, but the harvest was abundant, and the money received much greater than for any other crops to which their land had been devoted. It is a misfortune to the State that the initial campaign of the other factories should have been coincident with a bad season. Farmers feel that they have been deceived as to the merits of the crop and it will require a succession of more favorable seasons to regain their confidence and cooperation. The bad season of 1899 has, therefore, given a very marked setback to the industry. It has, however, sifted out the poorer farms and perhaps the more careless farmers, and better average results may be expected this year. It must be confessed, however, that the same attitude, not of hostility indeed, but of unwillingness to cooperate, does exist about all, or nearly all, the factories in this State.

"Beets have been grown almost exclusively by the owners on their own lands. At present, however, there is a tendency toward renting fields for a cash rent by the owners to men having more faith in the profits of the crop. I found this true especially at Holland and Benton Harbor and somewhat so at Bay City."

Let me say, when I was summoned to Alma and to Benton Harbor to talk with the people who were constructing factories, they asked me, "Will a factory work frozen beets?" And do you know that I could find no data in Nebraska or California on that point? Other factories may have succeeded; it may have been just the limitation of my knowledge, but I was unable to give those people any information on that question. They took the risk and found out that the factory worked up frozen beets all right. (Continues reading:)

"One of the main arguments at the outset against undertaking to make sugar beets in Michigan was that the period between beet harvest and the final freeze-up in the fall was too short. California and Nebraska had given little data as to either the possibilities of working up frozen beets, or the cost of burying in pits and thus protecting against frost. Our factories have had little trouble in working up frozen beets, but the cost of pitting and later removing from the pit and hauling to cars or factories have been a serious burden on the farmer. Owing to the limited capacity of the beet sheds which any factory can possibly construct and the great bulkiness of the crop, it seems inevitable that the farmer must deliver his products in installments, as called for by the factories. To retain them safely they must be buried, as once freezing and thawing ruins the roots. The dread of this job of first covering the beet piles with dirt and afterwards removing with pick and shovel the frozen covering has deterred many farmers from beet growing. To obviate this serious difficulty the Benton Harbor factory will undertake to receive all beets as fast as farmers can deliver them this year, or will pay the expenses of pitting.

"Over 50 per cent of the beets are hauled to the factories on cars which bring them from stations along the various lines from points up to 40 miles from the factory. The beets are hauled to the station when loaded on wagons. Good roads are therefore needed, and are now demanded by the distant towns and villages where the beets are grown. In this way the helpful influence of the factories on the character of the roads is widely extended."

In conclusion of this branch of my testimony, let me say that the grave questions in Michigan are two, first, the attitude of the farmer, who has been deceived innocently by the results of the Michigan factory its first season, and second, the adjustment of the relations between the factory and the farmer. No factory in that State knows whether it can afford to pay \$4.50 a ton for beets, as they now have promised to do, or not. Until the machinery is so far perfected in those factories that they can get a larger per cent of the sugar in the beet out of it, it is a very grave problem. Those are the two questions which confront us in Michigan.

Q. (By Mr. CONGER.) In your paper, in speaking of the factory at Holland, if I remember correctly, you said that quite a proportion of the stockholders in that company were farmers. I want to inquire as to the nativity of the farmers.—A. Hollanders mostly.

Q. Is it a fact or not that those Holland farmers had had previous experience in raising beets and knew something about the business?—A. Either in raising beets or similar crops. Most of them raised beets in Holland.

Q. In the old country?—A. Yes. They have large and thrifty families and are not afraid to work, and especially are not afraid to get down on their knees either in church or in the field.

Q. Was it in that section that the crop last year was to quite an extent a failure because of beets having been sown on sandy soil?—A. In the definite area north and west of Holland that statement is true. In the township of Robinson, you may remember, on the road leading from Grand Rapids to Holland, there is a definite area that is sandy. I am partly to blame for the mistake. I advised the sandy rather than the heavier clay soil of Holland because in all normal seasons it is the best soil.

Q. Well, do these beets grow well on heavier soil?—A. Yes; the best beets we had in the State, I think, except those growing on the alluvial—best Saginaw soils—were grown on heavier clay, better able to resist drought.

Q. You speak in your paper of land being rented to a considerable extent for the raising of beets. I want to inquire whether these renters are native or foreign born farmers.—A. I spoke of the trend in that direction, yes. It is more manifest at Holland, perhaps, Benton Harbor, and Bay City than elsewhere. Those renters are usually Germans or Hollanders. There is little bonanza farming yet apparent. That is, there is no land rented—large territories—and then worked by different gangs of men; but the factory, for instance, at Holland, has rented some land which it proposes to put in beets this year, and has had to pay \$8, \$12, and I am sure in some cases considerably higher rent per acre.

Q. These renters for the most part take this land in small tracts?—A. Yes.

Q. About what size tracts?—A. I can not say. They vary so materially it would be wrong and deceiving to give an average. For instance, I think of one man who rents 2 acres, because, as he said, he only had enough children to work that much; and another man I think of who has 5 acres; and another company have rented 103 acres; it is at Benton Harbor. Note that in this country, differing in that respect from our German instruction, lands tending to muck, if drained and thoroughly subdred, so much as to grow corn, are turning out excellent crops of beets of high percentage and purity. Now, I have mentioned this section rented by Stockwell & Bird at Benton Harbor. It is not a muck, it is an alluvial plot of land, full of grit. It is not simply decomposed organic matter. They have a pretty good yield, and this year they are trying it again. Their average yield, I do not think though, is much more than 8 tons to the acre. They had certain acres that were especially favorably located as to water table and so stood the drought all right, that turned out 25 tons to the acre. No use telling about that.

Q. These small renters—take this one you refer to who rented 2 acres of land—is he a native American?—A. No; he is a native of Germany—of the sugar-beet section there.

Q. He had experience in the old country in raising beets?—A. Yes.

Q. Well, is he typical of other renters?—A. Yes; typical of other renters.

Q. In other words, these foreign-born citizens in these sections who had experience in raising beets in Europe are becoming renters of land in this country to some considerable extent?—A. To some extent; yes.

Q. One place in your testimony you said, if I remember correctly, that an effort was to be made in Michigan this year to grow seed?—A. Yes.

Q. Where is that?—A. That is near the Alma factory.

Q. Is that being undertaken by the factory or by some farmer or individual?—

A. I can not state just the relation of the factory to the enterprise.

Q. Is it to be undertaken on a large or small scale?—A. On a fairly large scale, and it is backed by abundant capital, I understand.

Q. Do you know how many acres they intend to plant to beets?—A. It was not settled when I was up there, and, you will remember, it will take about 4 years before they will be able to put any seed on the market. The beet seed is a thoroughbred. It represents generations of careful selection. The normal content of sugar in beets is perhaps 5 or 6, and yet we grow seed that produce beets that test 18 and 20. Now, how is that done? Beet seed are sown. The individual beet is bored through with a little auger and the boring analyzed. While often growing from the same seed, beets range in per cent of sugar from 10 to 20 per cent. I am going over the ground hastily. The poor beets are all thrown out and only those kept for setting out the next year which test above the standard, which, we may say, is 16 per cent. Those beets set out by themselves in a row, a, b, c, and d, and the number of seed of each one of those beets is kept separately, and this is the seed from "a," this is the seed from "b," this is the seed from "c," and the seed is sown next year, and the beets are grown, and each one of these beets is analyzed,

and it is found out that the seed from beet "a," which tested 20 per cent of sugar, shows by a series of gradations from 12 to 20 per cent. Again a selection is made from beet "a" seed. Only those beets are considered that test above the standard again, and that process is repeated five times at least before they dare to put the seed on the market, so strong is the tendency to revert to the normal content of sugar; and so it is a very expensive process, and Dippe Brothers, Magdeburg, have spent a great many thousand dollars—I would not dare to say how many thousand dollars—just on analyses of beets alone last year, to produce seed, the best seed, of course, being consumed in Germany, and America using such seed as it can get. We have got to raise our own seed. Experience in Nebraska convinces me that American-grown seed, acclimated to our conditions, produces better results than foreign seed.

Q. Do they grow seed in Nebraska?—A. They did at a time; I believe it is abandoned now.

Q. Do you know if in California they depend upon American-grown seed, or do they get it from Europe?—A. I am ashamed to confess my ignorance. I ought to know, but I do not.

Q. (By Mr. A. L. HARRIS.) Do you know of any other seed company except the one you mentioned?—A. No.

Q. If the growing of sugar beets is a success no doubt companies will organize?—A. Yes; the installation of a plant to grow beet seed is so very expensive, and the returns put off so long a period that people hesitate to go into it until the beet industry is firmly established. Undoubtedly certain restrictions will be put upon the export of seed from Germany as soon as the industry of this country is developed enough to be a menace to their sales of sugar, and they will probably fix it so it will be very difficult for Americans to get seed, and we shall be obliged to raise our own seed.

Q. (By Mr. CONGER.) Do you know how many acres were devoted to the culture of the sugar beet?—A. I can make a calculation, but I can not tell you.

Q. Here is Joe Cox's report—44,000, he says.—A. Approximately 35,000 acres.

Q. Thirty-five thousand last year?—A. Yes.

Q. Can you tell us how many acres have been contracted for by the various factories there for the season of 1900?—A. Something over 37,000, if I remember correctly.

Q. Have the factories in each instance secured a sufficient acreage?—A. No; they all have except the West Bay City and the Detroit. Detroit is a little shy; that is, at Rochester; and the West Bay City is away below.

Q. The other seven are fairly supplied?—A. The other seven are fairly supplied, yes.

Q. To what extent have the factories in Michigan gone into the other States for this acreage?—A. No factories have gone outside of the State except the Kalamazoo and Benton Harbor; the Kalamazoo has 2,300 acres in Indiana and 1,000 in Ohio.

Q. To what extent has the Benton Harbor factory gone outside of the State?—A. My impression is it is 2,000 acres.

Q. As a matter of fact, then, the factories of Michigan have as much acreage contracted for this year as they harvested last year?—A. Yes; that is true.

Q. Well, in spite of the adverse season last year, you think this industry is one that will ultimately be a success and benefit to the farmer?—A. Yes.

Q. State your general opinion on that point, if you will.—A. I state this, that when the farmers realize that their harvest depends on their intelligent fertilization and management of the soil, and when they have sufficient confidence in the industry to put the necessary fertilizers and work on the crop: when they realize that the yield per acre is not to be so marvelous and phenomenal as some institute workers with a multitude of words lead them to believe, that they will on an average have successful crops. I think the matter will be well established, and it will be a great benefit to the State, pay them big for their beets, and the by-products are going to certainly increase the live stock kept. The practical experience of some of our feeders this year is doing more in this direction than all the theories that some of us have elucidated in the past.

Q. How will the profit in raising this crop compare with raising wheat?—A. Well, they compared very favorably last year, because the wheat crop was pretty nearly a total failure, and they will compare this year, because this year the outlook for wheat is still more depressed in Michigan than it was a year ago. Besides that, we have had a delightful spring, and the beet fields I tramped across last week and the week before were in first-rate condition. The season has been so good this spring, it has been so cool, that it has not retarded the work, and beet land is in excellent condition.

*Mr. A. L. HARRIS. I said to Dr. Kedzie, and also Mr. Rogers, that in the event they desired to ask any questions they could do so.

Mr. ROGERS. I would like to ask if Mr. Smith can explain why the percentage of sugar actually obtained is so much below the percentage of sugar that is found in the beet? What was the average per cent of sugar in the beet as delivered to the factories?

The WITNESS. I never have taken the pains to make an average of all the beets tested in the State, so I can not give it. The average per cent of sugar in the beet, not in the juice, I am sure exceeded 12. As a necessary consequence the average amount of sugar per ton of beets exceeded 240, and yet our factories did not get out more than 182½ pounds of sugar per ton of beets.

Mr. ROGERS. That is the largest, and it went from that to 124?

The WITNESS. From that down to 124.

Mr. ROGERS. A very great discrepancy somewhere in the matter of manufacture?

The WITNESS. Well, if I were able to explain to you why the West Bay City Sugar Company only received 124, I should be subpoenaed on that lawsuit as quick as those people heard of it.

Mr. ROGERS. I will say for the knowledge of the commission that I have examined a very great many German factory reports, and the factory loss ought not to be more than 1½ to 1¾ per cent.

The WITNESS. I might state there is another reason. The season last year in Michigan was so peculiar that beets were abnormal and they commenced with certain normal temperature of water in diffusion batteries. Dr. Kedzie may be able to explain the discrepancy.

Mr. ROGERS. Is the price paid the farmer for beets determined by the sugar of the juice or sugar of the beet?

The WITNESS. Sugar in the beet; and is determined by analyses made by the factory, by men appointed by the State, and the bounty is predicated on analyses made at the factory, not at the State laboratory, as in New York—one weighmaster working at both ends of the factory. It must be remembered in this connection, as to the efficiency of production, that our factories run from 350 tons up to 500 tons, and ought to be more efficient than smaller factories. I think that next year when our men become accustomed to their work and the very patent defects, I may say, in construction are corrected, that the per cent of sugar recovered will be very much larger. It has got to be.

Professor KENDIE. I wish to call Mr. Smith's attention to the sugar that is reported here. As I understand it, it is the first run, isn't it—the first product?

The WITNESS. Yes.

Professor KEDZIE. And I believe a considerable amount of the sugar which Mr. Rogers refers to, which is not realized in this first run, is contained in the molasses, and these are worked over in the second run and third run, and these are not reported as elements of the report for the bounty which is paid by the State. I think that the large disappearance—perhaps you will bear me out in the fact—that the disappearance of sugar is sugar contained in the second and third run, and is recovered in the second and third run or in the final waste of molasses, which counts for nothing.

The WITNESS. It should be understood, and I supposed it was understood by the commission, that the total amount of sugar reported refers to the total amount of crystallized A No. 1 granulated sugar that there is made; but there is still also an excess of second and third run sugar which is not reported, and which would reduce the per cent of loss somewhat.

Mr. ROGERS. But in the factory that is equipped with crystallizers in which the molasses goes into crystallizers, the entire amount of sugar is obtained as the first product and the molasses is disposed of, thrown away. The second and third run is only obtained in factories where the molasses goes into storage tanks and is left in them, and that does not prevail in most of the factories in Michigan.

The WITNESS. There is a good deal of that waste molasses still stored at these factories, in large tanks, to be worked over sometime during the season. Now, how much sugar they could get out of it no one can know, but it will reduce it a little, but not much. Our factories have been painfully inefficient in extracting the sugar from the beet. The factories cheerfully acknowledge it and are striving with might and main to remedy it.

Q. (By Mr. KENNEDY.) Are you acquainted with Mr. Oxnard?—A. Personally, no.

Q. Is Mr. Oxnard largely, if not altogether, connected with all sugar industries?—A. Yes.

Q. He is not connected with the cane-sugar industry, is he?—A. I do not know whether he is or not.

Q. You heard some weeks back a great deal of talk about the Oxnard sugar trust. I take it that would mean beet-sugar trust. Do you know whether it is

true that there is any such trust?—A. I have not heard that there was; no. Our factories are working entirely independently, as far as I am informed.

Q. Has there been any proposition for combination, looking toward bringing the beet factories under one management?—A. Only in certain respects. No; no organic combinations as I know of.

Q. As far as you know, there is no Oxnard or beet-sugar trust in this country?—A. No, not that I have ever heard of. I speak only with limitation, of my own knowledge. I do not know of any.

Q. (By Mr. CLARKE.) You formerly resided in Nebraska?—A. Well, I was there on a visit, that is all. New York is my home. I now live in Michigan. I was director of the experiment station in Minnesota, and as such I went around and watched the growing of the beets and watched the constructing of the Moline seeders and cultivators and matters of that kind. I was with Prof. H. H. Nicholson.

Q. (By Mr. A. L. HARRIS.) You spoke of the Moline seeders and cultivators. What do you mean by that—the implements?—A. Yes; they make a seeder that sows 4 rows, and, as Mr. Rogers says, they keep those 4 rows the same distance apart, and then they can take a cultivator and cultivate the same 4 rows, and by watching 1, you see, they are able to steer the cultivator for all 4, which is economizing labor; but, as a matter of fact, they have discarded that in our State and used the cultivator that cultivates 2 rows.

Q. Are there any foreign implements in this country—cultivators or seeders?—A. There were on the start, but they are entirely discarded. Our American implements, in the factory and out, now, are superior to the German make.

Q. The American inventor, then, is keeping pace with the demand?—A. Yes; but the exceeding fruitfulness of the beet seed gets away with him on the thinning. He can not find out how to do that—pardon the slang.

(Testimony closed.)

WASHINGTON, D. C., May 16, 1900.

TESTIMONY OF MR. CHARLES F. SAYLOR,

Special agent and investigator, United States Department of Agriculture.

The commission met at 10.18 a. m., Mr. A. L. Harris presiding. At 2.25 p. m. Mr. Charles F. Saylor, special agent and investigator of the United States Department of Agriculture, Des Moines, Iowa, was introduced as a witness, and being duly sworn, testified as follows:

Q. (By Mr. A. L. HARRIS.) You may state your name, your post-office address, and your occupation.—A. C. F. Saylor, Des Moines, Iowa. I am special agent and investigator of the United States Department of Agriculture, in charge of beet-sugar investigation.

Q. How long have you been so employed?—A. Since March, 1897.

Q. You may give the territory you have been over, and the line of work you have pursued.—A. I have been operating in connection with the experiment stations in all the various States except New England. We have been furnishing the State experiment stations with beet seed, and they have been furnishing these seeds to special lists of farmers that they made up who grew the beets. Then I have been visiting these stations and the farmers growing the beets, also meeting with business organizations and other associations with a view of promoting the industry locally, furnishing information, and, in a general way, promoting the industry wherever, in the sense of the Department of Agriculture, conditions were favorable and it was thought advisable. I have also been following out a line of investigation in the islands of Cuba, Porto Rico, and Hawaii, looking up the conditions of producing sugar in those regions from cane, with a view of ascertaining the cost of production, the amount of production, and such items that might be of interest to producers of sugar in this country, in view of the fact that those islands are now becoming possessions of this country, and to a more or less extent competitors, under advantages that are different from what they would be if they were absolutely independent. Now, then, that gives you an idea of what my work has been.

Q. Now, you may take up and give us the information as you have mapped it out, and members of the commission will ask such questions as you go along as suggest themselves.—A. I made an outline in order that what I might have to say would be carried through in a connected way. Of course this is entirely informal, and I am at your service to answer any question at call in any way you want. I can start out with this outline and at any time you can, anywhere you desire to,

ask any questions. It would bring it under that particular subject and keep it connected throughout. If you so suggest, I will take it up.

Q. If you please.—A. The investigation of this beet-sugar industry, so far as introducing it in the United States, has led to the conclusion that it is governed by conditions of climate, soils, and moisture; and, taking up the question of climate, our investigations have rather led us to conclude that the experience of Germany and France, who have had the most experience with this industry, is about right. They have settled that a temperature of about 70 degrees during the growing months is about the best climatic condition. The growing months, for instance, in the Mississippi Valley, we might say, would be June, July, and August. The growing months on the coast, you know, would be different, planting in February or March, and even on the coast it varies greatly; but sugar beets want about 100 days of good growing weather. It would be hard to state for the United States the growing months, where there is no general period that would be considered the growing months, because the seasons vary. On the west coast they aim to begin to plant beets in some places in February. In some places on the coast they would expect to harvest some of their beets in some of the places in July and August, and some of those factories are so fortunately located that in the variance of the planting time and harvest time in the different valleys they can have some valleys that will come into harvest earlier, and so fortunately balanced that they can begin harvesting as early as August, and have beets ripening as they go along with the manufacture of sugar, and really have a longer time for the manufacturing campaign. You take in places like the Mississippi Valley, they would expect really to begin to harvest the middle of October, something like that, you know, and all the harvest comes in at once; and they desire about 100 days' campaign in growing the beets, and another hundred in completing the manufacturing campaign. This would also be true in States like Michigan and New York, and States where the climatic conditions are uniform over the State in any particular region.

Speaking of the soils, where we have succeeded in demonstrating that beets are a success, there are two divisions: First, such soils as we find in the Mississippi Valley and States like New York and Michigan, where the fertility is largely due to their alluvial nature, the black loam, which is the formation of decayed vegetation; and, second, the other kind would be that found in the Rocky Mountain States and out on the West coast, originally due to the disintegration of the rocks, a silt formation, rich in mineral matter. These two formations of soil are also different materially in their physical properties, which will come out in taking up the question of moisture, which I will mention. Now, we raise sugar beets in this country by rainfall; that is to say, under conditions where all crops are grown by rainfall. This condition we would have in the Mississippi Valley, Michigan, Nebraska, New York, and those sections of the country where the crops depend entirely upon the real rainfall at the time of their growing. When we reach the Rocky Mountain region, we grow sugar beets there by rainfall and by irrigation. The desire is to start the germination of the plant and the early stages of growth by rainfall, and then the rainfall usually ceases, and they have to promote the further growth of the beets by irrigation. Now, we have another condition that prevails out on the coast of California. The coast country is the most extensive grower of sugar beets and at the present time the largest producer of beet sugar. Nearly all the beets of California are grown without rainfall. You may say they depend largely upon the supply of rain in the winter, and then by subirrigation or underseepage toward the sea the beets receive their supply of moisture while growing. It is a condition our scientists themselves are not agreed upon. I am not a scientist, but I have gone to them to get an explanation as to this condition. It is a question they are studying, and what seems to be the case is that water falls in the mountains and sinks in the ground, and in these regions where sugar beets are grown through seepage, or natural drainage to the sea, we have underground or subirrigation. These beets secure their entire amount of moisture for growth in this way, and if the amount of rainfall in the winter is sufficient the crop of beets will be secure and good; but if they have a prevalence of drought like they have had during the last three or four years, they are going to have a shortage in their beets such as they have had the last two or three years, ranging from one-half crop in the northern part of the State to a very small crop in the southern part. Then we grow beets entirely by irrigation, such as is the method in New Mexico. I have aimed to outline the influence of soils and moistures and climatic conditions, and will be glad to answer any question you want to ask on that.

Mr. A. L. HARRIS. I have none just now.

The WITNESS. In starting the sugar industry, and in the introduction of it in this country, there are two sides to be considered. One is the farm or agricultural side, and the other is the factory side or conditions which prevail favorable to a

factory. The thing that the farmer must study is the soil and kind. Unfortunately there seems to be a sort of a general misunderstanding about the kind of soil. People generally and newspaper writers and those who have tried to promote the industry have seemed to get the idea that sugar beets want a light soil, a sandy soil. I think this error has grown out of the fact that the industry started in the first place in Nebraska, where the soil is very sandy, and so far as the country east of that could get the information in the United States proper, it would be through investigations in Nebraska, for if they got into the West coast country, they would have to study coast conditions that did not prevail in any of the Eastern or Mississippi Valley States. That country around Grand Island and Norfolk is too sandy, and is not really good beet soil, but that is where the idea started, and people who made their investigations got the idea that beet soil, to make a success, should be sandy soil. Beets will do well in most any soil, but to make the greatest success, they are like corn or any other product that we plant, they should be given the very best soil that can be secured. There are some soils that will not succeed with sugar beets. With a soil that becomes compact, or a soil underlaid with hardpan, we are sure to meet failure in beet growing. We must have the fertility in the soil. The plant food must be there. Beets require a good, rich soil. Sand in the soil is all right. Provided it is fertile it tends to keep it loose, so that it would not be compact like hard clay or muck, or anything of that kind; but it must be kept in mind that the soil must be rich and fertile.

Now, I had that in mind yesterday while listening to your Michigan people. I was all over the beet fields of Michigan just prior to the harvest. Those people evidently were working under the idea that they needed a light soil. They selected their light soils and they had a very poor crop. My own impression is (I have not seen the statistics, but my own verdict would be) that Michigan did not average over 4 or 5 tons to the acre last year, and one of the mistakes, I think, was that they not only carried out the idea of selecting a sandy soil, but such soils of Michigan have been in use a good many years, some of them 50 to 75 years, and many farms are worn out for other purposes and sure to fail in growing beets. It only illustrates the point I am making, that they must be fertile whatever their physical character. Some sand is all right and proper, but the soil must be fertile. It must be a soil that the beet can penetrate. The tap root grows down anywhere from 8 to 12 feet, and the reason it can withstand drought so well is that like alfalfa it can go down and hunt its moisture in the stratas below. This can not occur if you have a hardpan; a soil with hardpan will not succeed.

The beet will succeed if it has a reasonable amount of moisture and it gets once started. After it has reached a plant of, say, four leaves, it is a very hardy plant. Up to that time it is a very tender plant. That is about the time that the usual drought conditions set in in any of these States, but it has sent down its tap root and is able to draw on the deposits of moisture in the soil below and sustain itself and make a good crop when other crops might fail, providing it has a fair start. A growth of, say, 2 pounds or 2½ is what a factory desires in the size of the beet. That is the theory of cultivating the beets, and you are under contract with the factory to produce a crop of beets that will not go over so many pounds, because when a beet grows over 2 or 2½ pounds to the beet it is coarse in its texture and consistency and does not present as much purity as it would below that. So the factory in contracting with the farmer always stipulates that a beet shall not go over so much, and shall contain so much sugar and so much purity. The one thing that it needs is sunshine after it has attained this growth; then you want droughty conditions. It is sunlight and air that produces the sugar in the beet, the entire product of sugar in the beet coming from the atmosphere and being worked out by the sunlight.

Another thing that should be particularly looked after when starting an industry is the question of labor. It costs about \$30 an acre in almost any region to produce an acre of beets, and that is mostly for labor. In the talk yesterday I understood Dr. Kedzie to say that in thinning out the work was done by cross cultivation. Didn't you so understand it?

Mr. A. L. HARRIS. In a slight degree; but the real thinning had to be done by hand.

The WITNESS. Well, that is one of the most laborious parts of producing beets. You understand that you have to plant enough beet seeds to secure a stand; as he explained to you, 20 to 22 pounds per acre. It is simply to assure yourself that you are going to have every beet in its place, because every beet relies on every other beet to keep it down from growing in size—to keep it down from taking from the soil things it ought not to take; and when you have a condition of things that you have not a stand and have vacant spaces, the beet has too much ground to draw from both in the matter of growth itself and in the matter of

taking up from the soil impurities, or things that we know as impurities in the sugar sense.

In order to thin out it simply becomes a question of hand labor. A man goes along with a hoe and chops out these beets at proper distances, whatever may be desired—8 to 10 inches—and then he is followed by a man who goes along on his hands and knees and by a dexterous move of the hand simply puts his fingers over the beet plant that he wants to retain, and takes the other hand and clasps the ones he wants to remove, and removes all but the one. That is quite laborious and costs a great deal of money, and at that season there is a great call for labor, and in starting an industry in the country it should be where you are absolutely sure the labor can be obtained.

The other side of the proposition, as distinguished from the agricultural side, is the conditions that should obtain for maintaining a factory. The first requisite is that you have good, pure water. You understand that when the slices are put into the diffusion and the sugars are dissolved from the cells and taken out, this water forms the juice for evaporation and should be pure from the fact that in the process of manufacturing the sugar all impurities serve to impede the process of extracting the sugar and the process of manufacturing all the way through.

Another thing that must be taken into consideration is that you must be in a district where fuel is handy or can be secured at cheap rates, because the sugar factory requires a considerable amount of fuel.

It also should be in a region where a good quality of lime rock or of pure lime rock can be secured. Not the lime rock that is desirable, perhaps, for plastering purposes, that might contain magnesia, but where the element of lime is pure.

The factory should be located in a locality that has good transportation facilities and where transportation is reasonable in expense. This is the one thing that gives Michigan the special advantage in location of factories. She not only has railroads playing everywhere reaching the markets, but she has also water transportation that gives the factories markets that are accessible.

Another thing that must be taken in account particularly in locating the sugar industry, from the factory side of it, is that it should be favorably located for markets, and that is another thing for which the State of Michigan is favorable and the State of New York, etc.

At the present time we have established 30 factories under this stimulus of encouragement that has been going on through the agitation of the papers, agricultural societies, agricultural writers, the Department of Agriculture, and the ambition generally of the people of this country to produce their own sugar.

We have in operation at the present time the following factories located: In California, 8. I mention California first because it takes the lead, not in the number of factories, but in the amount of output. California has the honor of having the largest beet-sugar factory in the world, a factory that has a capacity for 3,000 tons of beets daily, giving it an equivalent in round numbers of 300 tons of sugar daily, as it is estimated that about 10 per cent of granulated sugar can be produced from beets. Michigan follows with 9 factories, of which 8 were introduced in the State last year. Nebraska comes next with 3. Utah has 2 factories and 1 subfactory, or a factory that is really an auxiliary to the main factory, which is located at Lehi. There we have a new feature which is just being introduced in this country. The Lehi factory has been in operation about 6 years. About 30 miles away they have established a substation, or what they call a rasping station. They carry the process there to the extent of extracting the juice from the beets and then piping it down to the factory, a distance of 30 miles, where the juice is carried through the same process as is that of the other beets sliced in the factory itself. This is an innovation in this country, and should the experiment here succeed it will have a tendency to revolutionize the status of the sugar industry in this country. It will then be possible to locate a sugar plant at some favorable point on account of its facilities for fuel, shipping, water, etc.; and then in other sections not so favorably located subfactories can be built, the beet juices being piped to the main factory and worked up and the product placed on the market under the facilities pertaining to the main factory. This would bring the substations in close relations with the farmers, and it would be as advantageous as if they were located near the main factory, since they would be able to secure their pulp for feeding the stock, dispose of their beets, etc.; and that is their main relation to the factory. The next State is Colorado, with 1 factory; New York, with 2; Minnesota, with 1; Illinois, with 1; Washington, 1; Oregon, 1; New Mexico, 1. This gives in all 30 factories in operation in this country participating in the campaign of 1899.

Q. (By Mr. CONGER.) Do you know how many are projected for this year in the United States?—A. At the time I made out my report I investigated that very

closely and there were 6, but since then I think some others have materialized. There is quite a number that are very near the point of building. There has been more or less hesitancy on account of the question as to what effect our new insular possessions will have, and what will be the policy with reference to them; but I think there is in the neighborhood of 6 or 7 that are being built this year for the campaign this fall. There are 2 in Colorado and 1 in New York, and I do not just recall the rest.

Q. One in Ohio?—A. Yes.

Q. One in Michigan?—A. Yes, there is 1 there. There are 6 or 7 of them.

Q. Can you furnish a list of these 30 factories, with their capacity?—A. Yes, I can do that very easily.

Q. And the 6 or 7 that are building?—A. Yes.

We are starting an industry in this country with which it may be said the people generally have very little acquaintance. Even the farmers themselves and the capitalists who propose to furnish the money to build the factories are very much in the dark. We are building up a new industry with the view that we have the facilities for furnishing the people of this country with their own sugar, and with the possibility in the future that we may be able to export as we have done in most other lines where such industries have been developed. But at the present time the general information along these lines is very meager and the consequence is that education and the consequent advantage that comes from it has to be largely derived from experience, so that almost every new factory in starting has a great many difficulties to meet.

In the first place, farmers as a class are conservative. They have settled opinions and convictions about growing crops in general, and when they come to the problem of growing sugar beets they undertake to apply such experience as they have had in growing other field crops, while as a matter of fact it is entirely different. Growing sugar beets is the very highest type of field culture. It is intensive farming; in fact it is gardening, and such rules as would apply to most other crops will not apply here.

For instance, the farmer is accustomed to growing the largest ear of corn; he wants the largest hog and the largest steer, but here he has to resort to a system that will hold his crop down to a certain size. He has got to follow rules that will tend to produce in the best certain features. It is quality that must be secured regardless of quantity. Of course his interest is in the quantity, but he must know and understand how always to produce the quality as well as the quantity. A sugar beet treated right, from the standpoint of agriculture, is everything; if neglected, it is nothing. The farmer has to know this, and he can only know it by experience. This is the difficulty met from the farmer's standpoint.

We find the same thing with the capitalists or the men who are going to organize the company and furnish the money to operate the plant. They know nothing about the process of making sugar; probably very little about the markets for the sugar or what they have to contend with in putting the product on the market or in preparing it for the market. They must secure a man that is an expert in the manufacturing and must depend on this man or men until such time as experience and experience alone has given the information that makes a successful manufacturer of sugar.

In starting this industry in this country farmers and business men must acquire this information through experience. Until such a time it can not be said that we are on the basis of producing sugar to our best advantage so far as the cheapness of the product is concerned, but we are only on the threshold of the introduction of this industry.

It may be interesting to note that in the introduction of this industry we are working out some problems of our own. I will call especial attention to the central-plant idea which is now being experimented with at Lehi, Utah, where last year a pipe line was established and the juice piped to the central factory for a distance of 80 miles. Upon that experiment another substation is being established in the other direction, and the juice will be piped nearly as far. It is contemplated that several pipe lines will be started from this central plant should these prove successful, and then the central-plant idea will gain permanence in this country; the plan being to have one main plant surrounded at various points at proper distances with subplants, which will carry the process only to the extent of extracting the juices and pumping the same to the main factory.

Another feature in connection with the sugar industry that classes us almost as experimenters in that line in so far as we have participated in the business, is the fact that our people are entirely unacquainted with the value of feeding the pulp, the by-product obtained by extracting the sugar from the beet. In Germany the pulp is dried and prepared for the market the same as flax-seed meal and other products in this country, and sells in the feed stores in those countries for about 60 per cent of what these products bring. Dried pulp has a market in Germany

of about \$1 per hundred. There is no feed known, where it is understood, that is the equal of beet pulp for the dairy cow or for fattening steers, or for sheep and lamb feeding, for mares and for hogs. Its special value is as a dairy food. At the present time very few of our farmers appreciate the value of this pulp for feeding, and it is a fact that very few of our factories are able to realize much from this by-product. When the industry was started in New York it was my prediction to the manager of the Binghamton factory that they would realize at least \$1 a ton for their pulp within two years. I based this conclusion on the fact that New York is an old dairy State, thoroughly familiar with feeding all sorts of by-products, such as malts from breweries, etc., and being educated along the line of feeding those sorts of foods, they would readily take up with the pulp. It pleased me to be informed in this commission room yesterday by the manager of the same factory that were he free to make contracts for his pulp to-day he could get \$1 a ton.

Whole dairy districts have been established in California, running train loads of milk into San Francisco, solely from the fact that they are able to secure this pulp, and the factory secured \$1 per ton. Pulp can be very readily preserved. There is probably no other crop or forage that can be fed to cattle or animals of any description that can be kept longer or easier than pulp. When the people of this country so far learn the value of pulp and the factory shall receive for it a fair value, then we will begin to appreciate some of the corollary features of attempting to establish the beet-sugar industry, because this pulp feeding will be the very foundation of dairying and stock feeding.

We have a by-product in the molasses. At the present time this is a big loss. In Europe several things are manufactured from molasses—alcohol, vinegar, shoe-blackening—but the thing we expect most from molasses is that Yankee ingenuity will show us a way of extracting the actual sugar that is in the molasses, therefore giving it a greater value than may accrue from using it as a by-product, and I offer it as one of the problems to be worked out in this country along with the central plant and pulp feeding, etc.

There is a great deal of hesitancy in this country on account of our falling heir to a great deal of territory which produces sugar from sugar cane, and of course capitalists hesitate more or less about investment until they shall know more about the policy that shall obtain with reference to these new possessions. It is understood that sugar can be produced very cheaply in these islands, but the one thing that I wish to submit in this connection is that we know very little about what we can produce sugar for in this country from the simple fact mentioned above—that our experience is so limited that we are not working under the advantages that will naturally follow when the farmer and laborer and mechanic and investor and the expert in the factory are all thoroughly posted in their lines and working to produce sugar at its minimum cost in this country.

Q. Can you submit any figures to show how cheaply this cane sugar is produced in Cuba, for instance?—A. Yes.

Q. For what price per pound?—A. I was just going to make a comparison. We are able to produce in this country at the present time beet sugar under the best conditions for about 3 cents per pound, the cost ranging from 3 to possibly 3½ cents per pound. In Porto Rico it was my privilege to make an investigation of the cost of producing sugar in that country, and after making a careful analysis of the cost through a great many factories, I found that they could produce sugar at actual cost to themselves and place it on our markets for about \$40 per ton—short ton. This does not figure in our tariff, which is \$1.68 per hundred weight.

Q. Two cents a pound?—A. Yes; 2 cents a pound.

Q. Refined or raw?—A. Raw.

Q. What is it worth to refine sugar?—A. It is worth about 65 per cent on the west coast, and about 55 on the Atlantic.

Q. That gives the cost of raising a pound of sugar in Porto Rico and placing it on the market here refined as something over 2½ cents, according to your opinion?—A. Yes; that is, actual cost to themselves, figuring no profit to anybody anywhere. While I made investigations along this line in Cuba, I had not the facilities or time for giving it as close an analytical study as I had in Porto Rico, but the conclusions I came to were that it would cost very nearly the same in Cuba. I have recently been making investigations along the same lines in the islands of Hawaii. There are factories there that can produce sugar a great deal cheaper than that, but the cost of producing sugar in the Islands of Hawaii, and shipping to this country is about \$40 a ton on the average.

The Hawaiian Islands have been sending us about 250,000 tons, in round numbers. Last year the shipment was 282,000 tons. About 50,000 tons of this has been going around the Horn to the eastern coast, and the rest is absorbed by the Pacific coast and what is known as the Missouri Valley trade. The Hawaiian Islands, when they shall have been brought in to produce everything of which they are capable, such as new lands, better cultivation, etc., will be able to send

us at their maximum about 450,000 tons of sugar annually; but this increase will be at a very much higher cost, because the sugar will be produced on lands that require more expensive pumping—that is, higher lands requiring higher elevations of water for irrigation, very much increasing the cost of production. Porto Rico has been producing about 60,000 tons. Porto Rico is capable probably of doubling this amount. She will probably be able at her maximum to send us about 4 or 5 per cent of our present consumption.

Q. About how many tons would that be—5 per cent of our present consumption? A. I gave 5 per cent because I had figured it to be about 5 per cent.

Q. How many tons in the aggregate do you think Porto Rico can send in the future?—A. She will probably double her present output.

Q. At present that is 60,000 tons, and you think she may be able to double it, which it would be approximately 5 per cent of our consumption?—A. Yes. I have forgotten just the figures. I know that is what I estimated it at the time. As to Cuba and the Philippines, the question is somewhat different. Cuba is capable of a large output of sugar. I understand the same is true of the Philippines.

Q. Have you been to the Philippines?—A. No.

Q. Do you know how much we receive from there at present?—A. Not a great deal. The Porto Rican and Philippine trade was entirely with Spain, and their trade with us has just begun, so far as sugar is concerned. Hawaii has been sending us all her sugar.

The one thing that gives to Porto Rico and Cuba and the Hawaiian Islands and the Philippines their great advantage in the cost of production is the cost of labor. In Porto Rico unskilled labor is 30 cents a day, the laborer boarding himself; skilled labor such as brickmasons, carpenters, etc., 60 cents a day. This would make the wages of unskilled labor about \$9 a month. In the Hawaiian Islands sugar has been manufactured largely with contract laborers. These laborers are in most instances Japanese. The contracts are for \$12.50 to \$15 a month, the laborer boarding himself and the employer furnishing living quarters, medical attendance, etc. If we shall start with California as a comparison in the production of sugar, there we find that the same kind of labor in California is about \$30 per month.

Q. You mean Japanese labor?—A. Japanese labor and Chinamen. This is the conclusion I have come to after very careful investigation along that line. Not over 20 or 25 years ago this same labor was paid wages on a par with that now received by the Japanese and the Chinese in Hawaii, but under the influences that operate in this country, one of which was the exclusion of the Chinaman, these wage-earners receive at this time \$30 a month. Now, if we take it for granted that these influences are going to operate in Hawaii, now that it is American territory, and there is no doubt that there is a tendency now, a very noticeable tendency, for increase in wages in Hawaii, we must conclude that the wage-earners of that country will finally be receiving something equivalent to what is paid on the western coast of this country. In that event it will cost as much to produce sugar in Hawaii and place it in our markets as it does at the present time to produce beet sugar and place it in the market.

Q. Your idea is, then, that those who engage in the production of beet sugar in this country have little reason to fear this competition from the islands?—A. Yes. Is that the idea you get from my talk?

Q. We get the idea from your talk that, in spite of our having acquired this territory, it is still a safe business to engage in here.—A. Yes; perfectly safe.

Q. In your opinion, then, the future of beet sugar in the United States is not menaced by this acquisition of territory?—A. I do not think so. I do not think island competition is going to be extensively started at once, and I think every year we are in it that our people will reduce the cost of production, and that the islands will be increasing in the cost of production—referring to the Hawaiian Islands and Porto Rico and Cuba. Now, one of the great problems with these planters in Hawaii is where they are going to get further labor. There is a rapid development going on there in all the lines, demanding labor, while there are about 50,000 Japanese, and about—well, I do not undertake to state—quite a large number of Chinese. The Chinaman is estopped, you know, from coming into that country, the same as in this. He begins to diminish, and there is a development all along the lines in Hawaii, demanding labor. That demand is getting too great, and there is a tendency for wages to increase very rapidly, and that tendency is true in Porto Rico and Cuba. I notice all through those countries there are strikes for 8 hours a day and for stipulated wages. It sounds very much like agitation in this country already to hear the demands they are making, all stimulated by emissaries of organized labor in the United States proper.

Q. (By Mr. CLARKE.) So long as there remains a considerable difference in wages between those possessions and this country, and while our beet industry

here is still young and slowly growing, what would be the effect upon this domestic industry of importation of free sugar from these possessions?—A. We already have it free from Hawaii.

Q. Certainly; and have had for a long time.—A. If it is not to be a precedent on what shall happen further along with Cuba and the Philippines, I should say it would not have any effect so far as Porto Rico is concerned, or possibly so far as the Philippines are concerned, for a long time, because they have not the sugar interest developed there.

Q. Do you think there would be any effect of discouraging men from establishing factories or farmers from growing beets?—A. No doubt. I thought you meant what would be the effect in discouraging. There is no doubt it is very important; that it would discourage starting that industry a great deal. The very agitation of the question, you know, hurts the prospects all over this country.

Q. But you believe that the domestic market here is so large and likely to grow so much that we can consume all the sugar that we can produce and all that we would be likely to import from these possessions?—A. Yes; for a long time. The growth and development and increase in demand for sugar has been at a very rapid rate. I think it figures out an annual increase of 12 per cent, according to statistics compiled by Dr. Wiley, based on the statistics for the last thirty years.

Q. Have you compared the cost of producing cane sugar in Louisiana with the cost of producing beet sugar in the North?—A. I never gave that the careful comparison that I have of producing sugar in the islands, but the cost of producing sugar in Louisiana is considerably higher than it is in these tropical islands.

Q. (By Mr. A. L. HARRIS.) Why is that?—A. It is the difference in wages largely, and the difference also in adaptability. Cuba and Hawaii and Porto Rico, I suppose you might say, are more natural cane producers—produce heavier, and they produce longer.

Q. How long will cane in Cuba produce from one planting?—A. Oh, they get readily from 3 to 4 ratoons. Hawaii don't produce so readily in ratoons, but it produces a large tonnage. Take the leading plantation of the Hawaiian Islands, and it produces 10.1 tons of sugar per acre. I should say the sugar average on this plantation is a larger average than some States makes in beets, but for all the islands the average is about 5 tons per acre. I should say, with reference to this sugar industry, that it will develop in this country very rapidly, provided we do not hurry the idea that these tropical islands of ours are going to come in with free sugar, giving our own sugar industry a proper show in this country to start, and that the final result would be that we would all be producing sugar successfully. Our sugar districts here would be producing sugar a lot at an advantage.

Q. How could that encouragement be made?—A. Well, that depends. I myself am in favor of the tariff idea, providing that it is constitutional, because they produce sugar at a cost down there that they can pay a fair tariff and at the same time afford to make sugar. Under the present arrangement the American Sugar Refining Company and the combinations which we all understand control the sales of sugar have contracts with the planters of Hawaii to take up their sugar and refine it and put it on the market in this country, sharing, at a certain stipulated rate, in the profits. That information, I think, is pretty reliable as to Hawaii. I understand that the same thing is true with reference to handling sugar from Porto Rico. That being true, the only people that are interested in the free-trade proposition in Porto Rico would be the two people—the one who makes the sugar and the other fellow, who takes it and sells it—and not the masses, as the planter in Porto Rico is a foreigner both to Porto Rico and the United States, as a rule.

Q. (By Mr. CLARKE.) Have you studied the subject of bounty on sugar by the States in this country?—A. I have given that considerable consideration.

Q. What do you think about it?—A. Well, I think, in one sense, it is all right. I think it has a tendency to establish the industry in a State; I think it encourages it; but I think it produces inequality, because some States do not give any bounty. There are States that do. Take a State that might be qualified under all its conditions for starting an industry better than some State that offers the bounty, and the bounty State starts the industry. Those bounties are never carried out. The contract that the laws originally implied when they were put on the statute books are annulled as soon as the factory is started and the money begins to be drawn out of the treasury. The movement is started to get them off the statute books. Take the suits in Michigan. There are 8 or 9 factories that have started suits, claiming their rights under the bounty, and I think the bounty had a good deal to do to stimulate the starting of those factories. I do not think the bounty is really necessary for a factory to operate and succeed. I think a bonus is altogether wrong to offer. Well, in fact, nobody talks bonus any more.

Q. (By Mr. CONGER.) Are there any other States where manufacturers have had a similar experience to that in Michigan?—A. Yes.

Q. Where?—A. Nebraska has had exactly the same experience. They offered a bounty, and two factories were started, and then the next legislature refused to make the appropriation to pay it, and it went into the courts. I guess it is not decided yet.

Q. You say it did go into the courts?—A. Yes.

Q. Then the law was declared unconstitutional in Nebraska, or don't you know?—A. I do not know; never knew what the final disposition was.

Q. What would be your idea as to bounty; should it come from the National Government?—A. My idea is that a bounty, if anything at all, ought to be general.

Q. What do you mean by general?—A. Well, I mean national. The State of Iowa now refuses to give a bounty, but they exempt from taxes all investments of that kind for a series of years. Something of that kind, I think, would be practical. But, now, there is the State of Michigan, whose bounty is to be paid by taxation; you see they have a burden there. There must be something like \$300,000 in claims there.

Q. Claims for the last year; yes.—A. That is quite a heavy burden to a State like Michigan, and yet they have it on their statute books. I do not think, really, that a State bounty is necessary. I think there is enough in the proposition in itself, for the older factories are all doing well—all succeeding. Where they have continued for any length of time I do not think the bounty is really a necessary feature. To start with, of course, it is a very nice thing for the first year, because it takes them a year or two to really get themselves adjusted to their conditions.

Q. Your idea, then, if I understand you, is for them to offer it for a short period, say 2 or 3 years?—A. Yes. Of course I look at it from a general standpoint, without reference to any State, and I think the results of State bounties are not the most favorable for the general introduction of the industry in the country at large. One State offers a bounty and another don't. The offering of a small bounty for 2 or 3 years is probably not a bad idea, but should be limited in total amount and time to run.

Q. (By Mr. A. L. HARRIS.) What proportion of beets in California is raised by Chinese and Japanese labor?—A. I do not know just what proportion.

Q. Very largely?—A. Very largely. There are only 2 factories there where some other particular foreigners are supplied—foreigners that are accustomed and used to that sort of labor, where they attend to it; but the rest of it is done largely by Chinese or Japanese.

Q. How is that done; by hiring the man by the month or by the day, or by giving him a job?—A. They usually, you know, contract the work by the acre. The principal part of the work, you understand, is bunching and thinning and hoeing and weeding. Most any farmer can cultivate any amount of beets, as far as horse cultivation is concerned, but they contract with the laborer that he shall thin and bunch, and hoe and weed, and harvest and pile the crop for so much an acre.

Q. Is that contract made with one man for the entire plantation, or is it made by each individual taking a small contract?—A. Well, made both ways; made with each individual or several in combination, or some fellow furnishes a bunch of laborers and they make the contract with him.

Q. Does that come seriously in competition with the white labor?—A. Well, that kind of labor is nearly all done by Chinese and Japanese.

Q. Does white labor desire that kind of occupation?—A. No; nearly all vegetable raising and gardening, and all that sort of work, is largely done by Chinese and Japanese.

Q. Is Mr. Oxnard interested largely in the manufacture of sugar in California?—A. Mr. Oxnard has 2 factories; that is, his company, the American Beet Sugar Company, has one at Chino and one at Oxnard.

Q. Is he interested in the Nebraska company?—A. Yes; they have 2 there—1 at Grand Island and 1 at Norfolk.

Q. Do the companies that Mr. Oxnard is interested in control the industry to any extent?—A. I think not; they are building another large one now in Colorado.

Q. Is it a trust in any shape?—A. That is, the Oxnard factories?

Q. Yes.—A. Well, I do not know myself; just that those factories are all the American Beet Sugar Company. I do not know what the plan of organization is.

Q. What influence have they over the other beet-sugar factories?—A. Not any, I think, outside of the American Beet Sugar Company's factories. The rest are all entirely separate.

Q. (By Mr. CLARKE.) Those Oxnard factories number only about one-eighth of the beet-sugar factories in the country at the present time?—A. Yes; there are 30. This company owns 4 and is building another; that would make 5.

Q. Others being built in other parts of the country?—A. Oh, yes; I think the other factories act entirely separate and independent.

(Testimony closed.)

WASHINGTON, D. C., June 6, 1900.

TESTIMONY OF MR. ALEXANDER CLOHAN,

Farmer, Martinsburg, W. Va.

The commission met at 10.50 a. m., Vice-Chairman Phillips presiding. At that time Mr. Alexander Clohan, of Martinsburg, W. Va., was introduced as a witness and, being duly sworn, testified as follows:

Q. (By Mr. A. L. HARRIS.) You may state your name, your post-office address, and your occupation, please.—A. Alexander Clohan; Martinsburg, W. Va. Occupation, now, at present? I have a double occupation now.

Q. Well, what has been your occupation through life?—A. Mine has been farming; that is, for the last 25 years. I was not raised at farming.

Q. (By Mr. FARQUHAR.) Have you any official position now?—A. Yes; post-master at Martinsburg, at present.

Q. (By Mr. A. L. HARRIS.) How long have you been farming?—A. About 25 years.

Q. How extensively?—A. I have about 260 acres, and am in the fruit and truck business principally.

Q. Do you engage to any extent in ordinary farming, such as stock raising and wheat raising?—A. Only to a limited extent.

Q. You have been principally fruit raising?—A. Yes; that is, for the last 10 years at least dritted pretty much from the other—got out of that into the fruit as rapidly as I could.

Q. How extensively are you engaged in raising fruit?—A. I have about 60 acres under cultivation at present.

Q. Apples?—A. Apples, peaches, plums, and berries.

Q. Where do you find a market for your fruit?—A. Well, largely in New York; New York and Philadelphia are our markets.

Q. You may state, if you will, whether there has been any increase in the number employed in agricultural labor in your section of the State in the last 15 or 20 or 30 years.—A. No; I rather think there has been a decrease.

Q. To what extent?—A. Well, I would suppose it was one-fourth less.

Q. Why is that?—A. Well, I think largely from the fact that at that time we did not use any binders; there were no selfbinders used in the grain; all that was cut by the cradle, and the fact that in our country 15 years ago there was a good deal of meadow that was cut by the scythe. At present that is all done by the use of the mower, the hayrake, and the hayfork, and all the other implements; in short words, by the use of improved machinery.

Q. What effect has that had upon the condition of those that remained upon the farms—the laborers?—A. Well, they do not have as regular work now as they did 15 or 20 years ago. The season is pushed harder from the time we commence work and hurried through more rapidly than it used to be. Everyone at present aims to get his crop in just as hurriedly as possible, and wind up the farming season just as quick as it can be done.

Q. Is the work harder for the labor or is the drudgery taken off to some extent by present methods?—A. The drudgery is taken off to a great extent.

Q. Is work more desirable now than it was formerly?—A. Apparently it is, but there is a contradiction right there; the farming labor does not seem to be as good really as it was.

Q. Why is that?—A. Well, I think with our most intelligent young men it is the fact that better wages are paid in the cities and towns, and the most intelligent labor leaves the farm and goes to the town.

Q. Are the inducements greater in the factories in the towns than they are upon the farm?—A. Yes, from the fact that the hours of labor are not a great deal over one-half, and wages fully a half better.

Q. What is the comparative expense of living in the city as compared with the country?—A. Well, the ratio would be equally as great the other way. It would cost a half more, maybe more than half more, in the city.

Q. (By Mr. PHILLIPS.) Then, would they in the end get more by working in the city, do you think, than on the farm, considering the necessities—clothing, board, etc.—that they would require in the city?—A. Yes; I think an industrious and frugal young man, at the end of 10 years, would be decidedly ahead in the city.

Q. Decidedly ahead in the city?—A. Yes; that is, if industrious and frugal.

Q. (By Mr. FARQUHAR.) In the matter of wages, do lumbering and coal mining offer better inducements than the farm?—A. Yes.

Q. Well, have not a great many of your overplus of farming hands gone into

mining and into lumbering?—A. No. Where we are situated the most of our hands that leave us go largely toward Pittsburg and McKeesport and over in that direction, going into the manufacturing works. Some few go into mining, but not many.

Q. (By Mr. PHILLIPS.) The mines are generally worked by foreigners, are they not?—A. Yes; and I have found in my experience that generally miners grow up at that business and leave it for something else; but there are not many men that come up to the age of 21 or 22 that become miners afterwards.

Q. (By Mr. FARQUHAR.) Is the majority of your farm labor there American or foreign?—A. We have, I might say, altogether American.

Q. The foreign labor, then, goes into the lumbering and mining?—A. Well, now, I will not say that. A great many go to the lumbering, of course; but more of them go to the manufacturing. A great many have gone up into the lumber interest; and that is the better class of our American labor that goes often there.

Q. What foreign nationality predominates among your immigrants there?—A. We have very few foreigners: exceedingly few; not enough to make any impression; none whatever.

Q. (By Mr. PHILLIPS.) Then, do you have difficulty in getting American labor to do your work on your farms in your section?—A. Just now we have.

Q. (By Mr. FARQUHAR.) In the matter of intelligence, is the farming class really much ahead of what they were 15 or 20 or 25 years ago?—A. No; I really do not think there is very much advance.

Q. Have you made much advance in educational facilities there?—A. No; about the same. One month's schooling may probably have been added all around in the county in the last 15 years.

Q. (By Mr. PHILLIPS.) You have better schoolhouses and better accommodations for the pupils than you had 15 or 20 years ago, have you not?—A. Yes; there is an improvement in that line.

Q. And really better instructors, too, have you not?—A. Well, I do not know.

Q. (By Mr. A. L. HARRIS.) What are the hours of labor on the farm in your locality?—A. In our locality it is from daylight to dark.

Q. What time have you for taking meals?—A. Generally give them just long enough—until the horses are done eating. That seems to be the dinner hour.

Q. What is the average number of days your labor is employed in the year, about?—A. We generally have, say, from the 1st of April until the 1st of January—that is, the hands are generally hired for that length of time.

Q. About 9 months?—A. Yes.

Q. What is the pay?—A. Where the hands are boarded it is running from \$8 to \$15 a month.

Q. What is included in that except board, anything?—A. Nothing but board.

Q. No washing or mending?—A. No.

Q. Nor horse pasture?—A. No.

Q. How much do you pay them where the man boards himself?—A. We pay from 75 cents to \$1 a day. In the harvesting and busy season now we have to pay \$1; other times we get hands at 75 cents.

Q. How many days in a year will the transient labor be employed, usually; those that work by the day; irregular, we had better say, instead of transient?—A. It is a little hard to answer because there some of our day laborers, the better class of them, get almost constant employment. The others, the trifling fellows, we only hire just when we have to.

Q. Does that include rainy days as well as good days?—A. No; there is no employment there much for the irregular laborer in the wet; not any work on the rainy days.

Q. These irregular or day laborers, do they have permanent homes in the vicinity in which they work?—A. With us a great many of them have their own homes.

Q. Their own homes?—A. Their own homes; yes.

Q. Are very many of those men who have their own homes employed by the month or by the year?—A. A good many of those are monthly hands; some of them seem to prefer that way of hire.

Q. Working from the 1st of April until the 1st of January?—A. Yes.

Q. They own their own homes, as a rule, or does the farmer furnish them a home?—A. I think that fully a half of the labor in our county—I am only speaking of the county because we have peculiar conditions there—half the labor in Berkeley County own their own homes, coming from this fact: We have the North Mountain dividing the county, running up through it, and a great many get little homes along the mountain there, land being very low in price along the mountain. Then we have a belt of pine land running up through which is very cheap again, so that the men can get an acre for \$10 or \$15, and put up their houses. I

do not think that condition exists in West Virginia by any means, but I am merely speaking now of the county, as the facts are there.

Q. When the landlord owns the tenant houses what are the usual terms on which he lets to the renter?—A. In one or two cases there that I know of—not many—they pay about \$100 to \$150 a year, furnish a house, garden, cow pasture, and run, maybe, for two or three hogs. Several of our better farmers provide that sort of condition for their tenants.

Q. Does that custom prevail throughout?—A. No, not to any great extent; very limited.

Q. What is the character of the houses?—A. In those cases they are fairly good; about four rooms.

Q (By Mr. PHILLIPS). How is it with the class that live along the border of the mountain that you speak of? What kind of houses do they have?—A. They are very poor. They are nothing; very poor class of houses; one or two rooms and not much accommodations of any kind about them.

Q. (By Mr. A. L. HARRIS.) How much of a living does the tenant get from the privileges granted him by the landlord where the landlord owns the house and rents to the tenants who work for him?—A. Well, in a great many cases they raise enough potatoes or something of that kind to do them during the season, and cabbage and other vegetables, they raise that.

Q. The hand would have to buy—A. (Interrupting.) The flour and—well, there are some few of the better class that put up some meat, you know; say kill three or four good hogs; but it is a rare and exceptional class; they soon become farmers. This class of laborers in a very few years become renters.

Q. (By Mr. PHILLIPS). And then from that do they come to be owners of land after renting, as a rule?—A. There are a good many that have. Yes, I know quite a number that have.

Q. (By Mr. A. L. HARRIS.) Become farmers?—A. Become owners; yes.

Q. (By Mr. FARQUHAR.) Have your lands changed ownership quite frequently within the last 20 years?—A. There has been a considerable change within the last 8 or 10 years.

Q. What is the particular reason of that?—A. I think with us there were a great many men that were pretty badly involved, maybe, after the war, or bought when prices—well, at the war prices you might say, and they kept on struggling and struggling and trying and were able to pay their interest up to, probably, 1893, when the panic came on, and a great many of them had to go into liquidation, you know, and there have been quite a lot that were sold out. Probably more land changed hands for that reason, and settling up old estates that had been in liquidation for years. That has made many changes in our county for the last 3 or 4 years.

Q. Then did not the dividing of the States—productive lands—into smaller parts make a good deal of difference? Were there not some large estates in lands that it was impossible to get anything out of them in the body, the owners not having sufficient means to carry on the farming?—A. No; not to any extent in those two counties. Now, in Berkeley and Jefferson what are counted large farms there would be 300 acres. Three hundred acres is counted a pretty large farm there. We do not run much into those great plats.

Q. Your farms are getting smaller in area, are they not?—A. Yes; there are some of them being divided.

Q. Now, was it not the fact that mortgages or debts or incumbrances on those lands there caused a change in the ownership?—A. Yes; I think that was the cause.

Q. And did parties come in there that had little means, who were farmers, to take up those lands?—A. No; it came largely from the fact there of these people not being able to meet their obligations; struggling on, you know, until the depression came and they simply could not struggle any longer and they were sold out by the courts.

Q. Well, otherwise these men were land poor, as the expression is?—A. Yes; that is about it.

Q. (By Mr. A. L. HARRIS.) Have you any colored labor in your locality?—A. Probably one-fourth of the labor of our county is colored.

Q. What is the character of that?—A. The older class of the colored labor—men that are pretty well up in years—are a first-rate class of labor. The younger class, especially where they have a mixture of white blood in them, are a very trifling class of labor. We find that the black man is a far better laborer than the yellow man.

Q. Does he work on substantially the same terms that you have described as pertaining to the day white laborer?—A. Yes; only a great many more are hired

by the day than there are by the month, coming from the fact that farmers do not like to have to bother their women folks to have to arrange two tables and all that; so as much as possible they let them board themselves, and they are usually hired by the day, not so much by the month there.

Q. Are they trusty as a rule?—A. As a general thing they are.

Q. Work by themselves without slighting their work?—A. Yes; you can trust them pretty well. Generally pretty good to their horses, you know, and everything like that. Probably not as brutal with teams and one thing and another as you will find some of the whites.

Q. Do they supply to some extent the deficiency that you speak of of the labor going to the town instead of remaining on the farm?—A. Yes; but they have commenced to follow the same practice.

Q. They drift to the town, also?—A. They drift to the town, also.

Q. Does the white man who works by the month or by the day eat at the same table with his employer as a rule?—A. To a considerable extent. There are very few cases in which they do not.

Q. (By Mr. PHILLIPS.) But the colored labor do not?—A. No; there is no such thing allowed in the county whatever.

Q. (By Mr. A. L. HARRIS.) Have you a separate school for colored children?—A. Yes.

Q. What are your school facilities for both white and black—are they good?—

A. Yes. We can give from 6 to 8 months schooling to all.

Q. To all up to what age?—A. From 6 to 21.

Q. Have you a sufficient population of colored people to have good schools in all localities?—A. No; there are plenty of colored children that have to travel 3 and 4 miles to get to their schools on account of the sparse population. Some districts will only have 1 colored schoolhouse in the district.

Q. What do you call a district?—A. Well, our magisterial districts, answering to your townships.

Q. So many miles?—A. Yes. We have no townships; we have magisterial districts.

Q. Well, is that sufficient to give both the colored children and the white children good school facilities?—A. Yes; I suppose as good as could be devised without mixed schools, which would not work. Of course, for instance, if there is a schoolhouse in one district, why that is not made positively for the children in that district. All those living contiguous to it will be allowed to go to it, and then it is divided up pro rata between the districts. For instance, some of the districts have no colored schools because there are districts around them that have them, and their children are better supplied by having that than they would be by having one of their own. They simply pay their share.

Q. Are your colored schools taught by colored teachers?—A. Yes.

Q. Are they well qualified?—A. Yes; I believe that our colored teachers there are pretty well qualified.

Q. Is the course of study the same in both the colored and white schools?—A. Yes; just the same.

Q. (By Mr. FARQUHAR.) Is the school term the same in the white and the colored?—A. Yes; no difference.

Q. Established by law, is it?—A. Yes.

Q. (By Mr. A. L. HARRIS.) Are your colored teachers both male and female?—A. Male and female.

Q. (By Mr. PHILLIPS.) Which predominates?—A. Male.

Q. Which predominates in the white schools there?—A. Female—4 to 1.

Q. (By Mr. A. L. HARRIS.) Have you ever observed the qualification of the colored teachers?—A. Yes.

Q. Are they good or indifferent?—A. I think they are good. I think that they are very rigid in the examination of a colored applicant for a school. He has got to face a pretty rigid examination.

Q. And you have plenty of teachers?—A. Plenty of material.

Q. To supply the want?—A. Yes.

Q. How proficient do your colored children become in your school?—A. Just like the white children; some of them pass away up; can go into any sort of business, you know; others of course are just the reverse.

Q. Have you any suggestions to make in regard to your school facilities for either colored or white, or amendments to your school law?—A. Well, this is only an idea; I would like to see some of the branches taken out of the public schools and something more directly pertaining to agriculture put in.

Q. Now, if you have anything to suggest upon that line, please do so.—A. Well, I think that for the average farm boy it would be far better to give him an idea of botany and agricultural chemistry than to teach him the languages.

Q. You do not teach the dead languages in your common schools, do you?—A. We do in our towns there; yes.

Q. Well, I had reference to the country.—A. Well, a great many of our country boys go in, you know; go into the town; all that can reach the town school.

Q. To what extent would you teach branches pertaining to agriculture in the country schools?—A. Well, at least enough to develop a thorough taste for the studies; to make them interesting to them, both botany and chemistry. I would like to see them experimental, so that the children would be taught to know the reason why plants grow, and all that, and what they were fed on.

Q. Would you have text-books on that subject or lectures by the teachers?—A. I would prefer text-books.

Q. And require an examination for the teachers on that line?—A. Yes; that would be my idea.

Q. Have you ever suggested that amendment to your school law?—A. No; I have never been in a position when I could; I have had no chance of offering suggestions.

Q. Where is your experiment station?—A. Our experimental station is at Morgantown.

Q. You might briefly outline the work at your experiment station at least.—A. Well, our experimental station has spent a good deal of its time in what a great many of us thought was foolishness, proving that lettuce could be raised successfully under electric lights, and mushrooms could be grown under certain conditions, and that cucumbers could be made in a hothouse—you could raise them to have them all winter—and a great deal of that which we all think would be a great deal of benefit if we were all retired millionaires and were running our conservatories, but we do not exactly see where it interests the fellow who has bought a farm and only paid \$1,000 on a \$5,000 or \$8,000 farm. We do not see how it is going to help that fellow out.

Q. You think it is not entirely practical?—A. I think that a great deal of their experiments are of no practical value to the farmer.

Q. (By Mr. FARQUHAR.) What do you say to the practical feature of the analysis of soils, independent of plant raising? How could you ever find how to raise anything at all unless you knew what your soil was and what it lacked?—A. The schools would teach this after thorough training. I think you can almost learn by the eye. If a field was very luxuriant in its growth, we would say there was an abundance of nitrogen in that soil; that there was not any use of adding any to it. If the growth was very poor and scanty, we would say that it wanted nitrogen. If the fruit did not color well, why we would at once think that potash was what was needed or phosphoric acid to remedy that; but I do not think that it is practical to analyze soils, because there are so many conditions in one field. You might take a sample of the soil at this end of the room and at the other end, and it would be of a totally different kind. We have been trying that in the last year; sent a lot of soil samples down, quite a lot of them.

Q. (By Mr. A. L. HARRIS.) The experiment in the chemical laboratory is as to what the constituents of your soil are?—A. Yes; of course, every farmer has got to be continually experimenting.

Q. What do your farmers raise mostly upon their farms—those engaged in regular agriculture?—A. Wheat and corn. They are the staples.

Q. Are they grown pretty successfully in your climate?—A. Yes; both.

Q. What succeeds best in the way of fruit in your locality?—A. Well, on our uplands the apple and peach are the two great crops.

Q. What are your hopes for the future in the fruit raising?—A. We hope to make our county the greatest fruit county in West Virginia.

Q. (By Mr. PHILLIPS.) Can you raise plums?—A. Yes.

Q. Cherries?—A. Yes.

Q. With success, and pears?—A. Yes; the cherries with us come spontaneously. We are in an upland like that Piedmont Valley. They have the same conditions. They grow up. Every fence corner has a cherry tree whether you ever planted any or not.

Q. What kind of cherry trees?—A. Well, what we have are always sweet cherries, black hearts, gray hearts, and red hearts, and all those different heart cherries. They grow spontaneously.

Q. They were not there originally?—A. No; I suppose they were brought there from some source and simply grew up.

Q. Do you not have wild cherry in that section? Have you what is called wild cherry?—A. That has been nearly all out. It grows up in very good shape.

Q. (By Mr. A. L. HARRIS.) Where do you market your fruit?—A. Very much in the Eastern cities, Philadelphia or New York. Occasionally when there is a failure in the West we go to Chicago and Cleveland.

Q. What are your facilities for marketing?—A. Our facilities are splendid. We get into Washington here in some 3 or 4 hours; get into New York in 8 or 9 hours; Philadelphia in about 6; Pittsburg in about 6; Cleveland in about 12. We are located so that we can, by wiring, generally find the condition of the market, and we can ship from our place whichever way we want.

Q. Do you ship by express or fast freight?—A. Those who have shipments of any extent to make are using the fast freight. Those of us who have been small shippers, like myself, have the express; and there comes in the trouble to the fruit grower.

Q. You may state that trouble, if you will.—A. In shipping a crate of peaches to New York, to ship by fast freight with the refrigerator cars costs 17 cents a crate—that is about what it costs—and if we put them in by express it costs from 50 to 60 cents. The difference between the two is more than the price of the fruit.

Q. (By Mr. PHILLIPS.) More than the profit?—A. Yes; a great deal more than the profit. It is so much so that one man can get along first rate and the other man does not get anything. That is the greatest drawback to the small grower that we have.

Q. (By Mr. A. L. HARRIS.) Have you any complaint to make in regard to your facilities for shipping by fast freight?—A. No; not where we are able to have a quantity. The only thing is now to have a quantity. If we are shipping 500 crates a day—that is, a carload—we have no reason whatever to complain; but we can not get out if we have only 100 crates; we are just simply left out.

Q. How do you overcome that trouble?—A. We are attempting to overcome it. We planted last season some 40,000 trees, 8 or 10 of us together, at the same periods and at the same time, thinking that we would get together when this fruit will come to bearing and always can ship by carload. That was the only way that we could plan to get out of it. We found out, by planting just a few acres and only having 25 or 30 crates to haul in a day, that whatever we can not sell at the local market we might as well throw away. The express company gets it all.

Q. You can not ship part carload lots?—A. No; we have got to get carload lots. Our biggest growers now cut their own ice and ice their own cars and everything—our largest growers.

Q. Has that experiment been operated long enough to know what the result will be?—A. Yes; I think that the Allegheny Orchard Company has proven that that is the proper way to do it.

Q. (By Mr. FARQUHAR.) Where is the Allegheny Company located?—A. Up in Hampshire County, right above us.

Q. (By Mr. A. L. HARRIS.) That is a company?—A. Yes; it is. We are all of us individuals. We have no company in our county. We are individual growers.

Q. You expect to work together?—A. Yes; just simply cooperation among neighbors; that is, on the last planting that we did.

Q. (By Mr. CLARKE.) In other words, you entered into a sort of combine to beat the express company, did you not?—A. Yes; tried to see if we can not in some way save part of that freight.

Q. (By Mr. PHILLIPS.) How much land has this company of which you spoke, the Allegheny Company?—A. They have now about 600 acres.

Q. Are there any larger plantations than that in your section or in your part of the State?—A. No.

Q. That is the largest?—A. That is the largest.

Q. And only 600 acres?—A. Yes; that is, in bearing. They have about 1,000 acres altogether.

Q. What do you chiefly raise?—A. Nothing but peaches; they are totally in the peach business.

Q. (By Mr. FARQUHAR.) How long since your section of West Virginia went into fruit raising?—A. It is not over 15 years since they commenced to plant to any extent. There was but one fruit grower in the county before that. That was Mr. Miller, and his sons now are at the head of all the fruit industries in that end; this Allegheny Company and all the others.

Q. (By Mr. A. L. HARRIS.) Are the natural conditions of soil and climate favorable?—A. Yes; very much so.

Q. (By Mr. FARQUHAR.) The inducements, of course, of forsaking general farming and going into fruit raising are such as to make the fruit raising somewhat permanent in your section?—A. Yes.

Q. In other words, you are making more money substantially, year in and year out, than you did before in general farming?—A. Yes; those that have gone into it have more than doubled what the others have.

Q. (By Mr. A. L. HARRIS.) I wish you would state to the commission whether you have any trouble in marketing your product after it reaches the place of destination. Probably you might describe how it is marketed at that place.—A. Well, if any of you have ever had experience in shipping to commission houses—I do not know whether any of you gentlemen are commission merchants or not—but I can just describe it, as I asked Mr. Miller one time about a certain party, and he says: “I think he will cheat you a little less than any of the other fellows.” That was the highest term that he could get as regards the honesty of it. Well, now, that is not my impression, nor was it Mr. Miller’s. Mr. Miller just said that. I know some of them that are men of the very highest honor and integrity—I am certain of that—in the commission business; but it is very uncertain, shipping to the commission houses.

Q. (By Mr. PHILLIPS.) They make claims that it is damaged when you think it is not, probably; something of that kind?—A. I think there is more done in this way: That they have favorites, maybe the canning houses; that they will often unload a fine car as being damaged, when there was not any damage. For instance, I shipped to a party 100 crates on a Monday to Pittsburg. Now, we picked on Monday and shipped Monday evening. We thought that we were a little closer to the Pittsburg market than anybody else, and I looked for a drop in peaches; I thought that the time had come when there would be a drop. Well, those peaches arrived there and were sold on a Tuesday. On Tuesday I shipped 50 crates. When the returns came in for the 50 crates that we shipped the latest day, I think that I got \$1.50 a crate, but I was notified that the 100 crates had arrived there in the glut, and I think I got about 40 cents; so I was satisfied that there was something wrong.

Q. (By Mr. A. L. HARRIS.) Did you investigate?—A. There was no use for me to go and investigate.

Q. Have you any suggestions to make to better the condition of the shipper?—A. No; it does not seem to be practical.

Q. (By Mr. FARQUHAR.) Can you not make those combinations among yourselves, on the receiving and selling, and have a party in these large cities, a man known to yourselves?—A. No. For myself I have about solved it this way: To hunt out a man that I think is thoroughly honest—a commission man—and just trust him implicitly; just put the crop in and try to put it just about average; just ship the same thing right straight through; it does not do to go off and change your market every day or two. Whenever some other fellow offers you some great big price, why, look out.

Q. He is going to make it up?—A. Yes. It is hard to combine, for the simple reason that the farmer is not any more honest than anybody else. If I ship my fruit first class and the other fellow puts all his knotty and wormy ones in, and we put them in the car and pro rate them, you can see where the trouble is when they get down there.

Q. (By Mr. A. L. HARRIS.) You have to select your fruit when you ship together?—A. Yes; and that is a difficult thing to arrange. The fact is, I am puzzled a good deal about it.

Q. What are the earnings of capital invested in agricultural property as compared with capital invested otherwise?—A. Through our section the landowners claim that about 3 per cent is about what they get out of it; that is, the landowners.

Q. Now, does that mean 3 per cent after a living is taken out?—A. No; those are the owners, not the men that till. The landlord claims that he gets about 8 per cent; that is about all that the farms now are paying. That is on this basis: That the tenant will give him two-fifths of the products of the farm, and that those two-fifths will give the landlord about 3 per cent on the money invested.

Q. You might right there touch upon the subject of crop sharing—what the terms are.—A. Well, that is the general way. The tenant finds everything; the landlord has nothing whatever to do, and the tenant delivers wherever the landlord will say, we will say, will deliver two-fifths of the gross product of the farm, not the net—two-fifths of the corn and the hay and the wheat. The fodder and straw, of course, is retained on the farm. But if the landlord finds the teams and everything, the tenant gets one-third of the proceeds.

Q. Who pays the expenses, blacksmithing bills?—A. The tenant.

Q. Keeping up the utensils?—A. The tenant.

Q. To what extent does crop sharing prevail in your locality?—A. I suppose one-half.

Q. One-half of your land is taken that way?—A. One-half of the land, yes.

Q. (By Mr. FARQUHAR.) Does the farmer or cropper there furnish his own horses or implements for his farming?—A. Yes, if he gives the two-fifths; if he gives the one-third, the landlord furnishes them.

Q. Well, when you said nearly half of the farming there was based on this ownership entirely of the land, the owner receiving two-fifths and the farmer furnishing all the rest, is not that a pretty large average? Are there so many landowners that have nothing at all but the land and the buildings that can get two-fifths?—A. Yes; quite a number live largely in the towns. Our lawyers own farms, our bankers own farms, and our doctors own farms, and all of them reside in the city and own their farms.

Q. That class of farmers have their workable implements and everything of that kind there on the farm and hold three-fifths as against two-fifths and the land?—A. Yes.

Q. What is the condition of those farmers? Do they make money; are they prosperous; do they ultimately get so that they can buy land for themselves?—A. Yes; I think that the most of them, when they get on a good farm and stay on it 12 or 15 years, ultimately become owners.

Q. There is not such a thing as store liens there in West Virginia?—A. No; none whatever.

Q. Your people are in better condition than any of that class of renters?—A. Yes. As a general thing, the landlord, if there is any little something needed, will advance to the tenant. It is something almost unknown to give a lien on your crop; that is almost unknown.

Q. Does the law in the State of West Virginia allow you to make a lien?—A. Yes; you can give a lien.

Q. (By Mr. A. L. HARRIS.) What is called a chattel mortgage?—A. Yes; you can give a chattel mortgage.

Q. Any form specially for a crop lien?—A. No; still I have known one or two cases where people were leaving and wanted a little, and that was done.

Q. (By Mr. PHILLIPS.) Do the colored people do much farming on the shares you have alluded to, or is it generally the whites?—A. Generally the whites.

Q. Are there any croppers amongst the colored people in your section?—A. One of our largest farmers has a colored cropper, but he furnishes everything for him in that case.

Q. (By Mr. A. L. HARRIS.) What have you to say in regard to the taxation of agricultural property?—A. Well, that is the most serious matter, I think, that the farmers in our section have to contend with. The practice in our State is to make the real estate bear the whole burden of the taxes. If a man buys a farm for, say, \$10,000, and he only puts \$2,500 into it, he has instantly got to pay the taxes on the \$10,000, if that is the value of the farm.

Q. (By Mr. FARQUHAR.) In other words, he has got to pay his general taxes as well as his interest for purchase?—A. Yes; he pays the tax, as a rule, on his indebtedness.

Q. (By Mr. A. L. HARRIS.) Well, now, explain how he pays on his indebtedness?—A. Because, when a man buys a piece of property, say, worth \$10,000, and he pays \$2,500 on it, he has only got an interest in his farm to the amount of \$2,500, and the other man has \$7,500 in it, and the other fellow has merely got an interest in there as long as he keeps up the interest.

Q. Is there anything added for interest on account of taxes on the note?—A. Yes. The farmer goes to borrow money and he will be told that he will have to pay 6, maybe 7, per cent, because the loaner will tell him, "Well, I have got to pay 1½ cents county tax, and consequently I have got to put the interest up to cover that amount." And the farmer has got to pay the higher interest just in proportion as the tax is higher.

Q. Then he pays a tax on the real estate?—A. He pays really the tax and the tax over again to the loaner.

Q. Is this note required to be listed for taxation?—A. Our laws call for all evidences of indebtedness to be listed, but the fact of the matter is that they are not listed. The assessor as a general thing is a candidate for reelection and he does not want to have the ill will of this man. The man that loans money is generally an influential man, and he does not want his enmity or ill will, so he does not hunt him very close.

Q. You spoke a moment ago about real estate paying the taxes so largely in your county. Is that because you have no notes or mortgages?—A. It is because the real estate being in sight there and having a fixed value the assessor simply goes to the land book and he gets all that tax in a few moments. He has no bother with it, simply goes to the land book and it is taxed there. Once every 10 years we revalue our lands. He does not need to have any bother about it at all; that is fixed up simply by the county clerk; the assessor has nothing to do with our land taxation; that is a fixed tax. But the assessor, in coming around to get all these evidences of indebtedness, never finds these people, and when he does find them they simply just refuse to list the notes and securities.

Q. (By Mr. PHILLIPS.) Then have they not a right to assess them according to their own view; if a man does not make a list do not they levy the tax on him according to their own judgment, and then he has a right to complain?—A. Yes; but he can not levy a tax on notes or mortgages or that sort of thing unless he can see them, you know. He has got to know. I generally say to the assessor when he comes up to my farm, "There are the horses, there are the cows and everything; you value them, that is what you are here for." But when he goes into the house a man does not open his desk and say, "Here is this mortgage and that note and that bond." He does not show them.

Q. He then has no authority to assess taxes unless they are of record, like judgment notes or mortgages?—A. No; unless he can see them.

Q. He can not make an assessment of what a man is supposed to have and then if he complains let him prove his assessment is too much; they do not do that?—A. No; they do not.

Q. (By Mr. A. L. HARRIS.) Have you any remedies to suggest for this great deficiency?—A. The remedy that I would suggest is of a twofold nature. I would allow the borrower to simply make this a matter of record, and when he paid this tax have the State allow that to be credited on his interest to the other party. For instance, if I would pay the taxes on the \$10,000 I would have a right to a credit on my note for the tax on the \$7,500. That would be one. The other would be this, that I would require that any note or any evidence of debt that did not have the assessor's stamp on it to show that it had been listed for the purpose of taxation would simply be declared uncollectible, unless it showed that it had the assessor's stamp on it every year.

Q. (By Mr. PHILLIPS.) That would be pretty radical?—A. I think that would reach it; it is a very serious condition of affairs; I think it is the greatest drawback that the agriculturist has to contend with; that is my honest belief, that there is nothing equals that.

Q. Is there any State that has such a law, that requires an assessor's stamp in order to make a note collectible?—A. Not that I know of.

Q. (By Mr. A. L. HARRIS.) Who fixes the rate of taxation in your State?—A. The State fixes it to a certain amount.

Q. That operates equally on all property?—A. Yes, all over the State; with us 35 cents on the \$100 valuation.

Q. And the county tax—who fixes that?—A. The county then levies a tax; in our county it is 45 cents on \$100; then comes in the district and school taxes, which are added to that; the district levies so much for its schools and the county levies so much; we divide it up in several funds—a road fund, a school fund, a district fund, and county fund.

Q. Who fixes the rate in your county?—A. Our county court, composed of three commissioners.

Q. Elected by the people?—A. Elected by the people.

Q. Do the farmers have representation on that court?—A. There are always farmers on the court in our county.

Q. Who levies and fixes the rate in the district?—A. Our school commissioners.

Q. Are they farmers?—A. Yes; generally farmers.

Q. The local tax is greater and heavier than the State tax?—A. Oh, yes; by far.

Q. And the district tax is frequently greater than the county tax?—A. Yes. Of course our school tax—that is a district tax—is the heaviest tax.

Q. And your road tax?—A. Our road tax is laid by the county court, but levied on the districts; it is collected in each district so much; one district may pay 10, another 15, and another 20, according to the needs of the district.

Q. (By Mr. PHILLIPS.) How is your poor tax levied?—A. It just goes into the general county tax.

Q. (By Mr. A. L. HARRIS.) You have no suggestions to make except the one you have just made in regard to your tax laws?—A. No.

Q. Has there been any decline in the value of agricultural lands in your locality?—A. Since what time?

Q. Say 20 years.—A. No. Land is fully as high as it was 20 years ago.

Q. (By Mr. PHILLIPS.) How is it compared with war times? You spoke of that some time ago, that there had been a great many persons sold out on account of the depreciation.—A. I had probably 4 farms in view, but the one I had particularly in view was bought at \$55 an acre along about 1868 and it was sold at about \$28, and now has been resold again at about \$40, showing that \$40 was about all a man could ever afford to pay for it at any time; that the other was too high—above what it would produce interest on.

Q. Was that about the difference in the valuation of land in 1868 and now?—A. Yes.

Q. There has been a considerable depreciation since 1868?—A. It is not worth as much now as it was in 1868, but it is worth fully as much as it was in 1890. Land is worth fully as much as it was then. It was the class that bought at that particular time, just after the war, that suffered the most.

Q. Is a farm worth as much now as it was in 1868 for farming, not fruit-growing, purposes?—A. Yes; it is worth as much. There are two classes of land; our heavy limestone soils are not particularly adapted to fruit growing, but they are splendidly adapted to grain and grass growing, and these are the farms that are on the market. One at our place last Saturday—a rough limestone farm—stopped at \$39.50 an acre and will be sold again next Saturday at about \$45 an acre.

Q. What would that farm have brought in 1868?—A. The chance is it would have brought \$60 or \$70; because it seemed they had \$3 wheat, and all a man seemed to want to do was to buy a farm, no matter what the price was.

Q. (By Mr. FARQUHAR.) Three dollars, worth about \$1.50—these rates you are naming were based on the inflated currency at that time?—A. Yes; altogether, of course.

Q. (By Mr. A. L. HARRIS.) A rather abnormal condition?—A. Yes. Lots of old men in our county that I have talked with say that land in that section has been of a certain fixed value for nearly 100 years. The best land would bring to-day \$50 and \$60.

Q. (By Mr. PHILLIPS.) Speaking of inflated currency, what was land worth just before the war, in 1858, 1859, and 1860; about what was it worth then as compared with now?—A. I would have to speak totally from hearsay; but this class of land was sold at \$40 and \$50—about where it is now.

Q. (By Mr. A. L. HARRIS.) What is the advantage of organization among farmers?—A. We have two that have amounted to anything in the county, the Farmers' Alliance, which was very short lived with us; and we have the Patrons of Husbandry, which has had 25 or 30 years' existence, at least. The farmers that connected themselves with the Patrons of Husbandry, I think, improved their methods of farming, and it improved their methods of buying and selling. I think we bought fertilizers within 4 or 5 years after the Grange was organized—we had got the price down nearly one-half on fertilizers by buying in carloads; and we sold to some extent; but the great benefits, I think, derived from the farmers organizing are in the sociability produced and in the moral features. I think that is even more than the financial. The fact of farmers being so isolated caused them to become selfish, you know, and they did not care; men that were wealthy were willing to have a sort of run-down appearance about their concerns; and having committees visiting around seemingly resulted in a general looking up of the whole business. For instance, if a Grange committee was going to visit my farm I would want to put in about a week getting ready to receive them, get the briers cut out, fences straightened up, and things of that kind. I think the farmers' organizations are of great benefit in that way, as well as in the financial way. And, of course, when we meet and discuss and argue how a certain man would raise very fine crops and how another would totally fail, this means as much as the other. I think it betters the farmers' condition all right—that is, the Grange. The other one went right into politics and was apparently of no value to anyone. That seemed to be the difference. The Farmers' Alliance drifted right into the political feature. You must leave politics outdoors.

Q. (By Mr. PHILLIPS.) Were they divided in your region—some Democrats, Republicans, and Prohibitionists, or Populists?—A. Every kind. Everybody went into it.

Q. They did not use the old organization in favor of one party, but they were going into politics?—A. They were going to be a great political party without regard to the other parties. We were going to be the party and get the offices. That was the idea of the Farmers' Alliance.

Q. (By Mr. FARQUHAR.) You thought there were more farmers than other people and the farmers might as well have the offices?—A. That seemed to be the theory.

Q. (By Mr. A. L. HARRIS.) Is there any increase in the cost of production of farm products in the last 20 years?—A. I think not. I think it has been the other way.

Q. Cheapened?—A. Yes.

Q. By what means?—A. By the use of labor-saving machinery.

Q. Have you a pure-food law in your State?—A. No; not especially.

Q. Have you anything to suggest in regard to the importance of pure-food laws.—A. We ought to have one.

Q. Why?—A. Because Pennsylvania and other States have pure-food laws, and the grocery men in those States, if they would get anything that would not pass inspection in their own State—would be condemned or anything of that kind—

there is nothing to hinder them dumping it over on us where we have no law. I think the pure-food law should be general and apply everywhere.

Q. Wherein is the farmer interested any more than any other individual in the pure food law, properly executed?—A. The fruit grower, I will say, instead of the farmer, is interested very much; he would be, to a large extent, say, in the question of vinegar. The acid vinegars have largely taken the place of cider vinegars and cut the prices down as low as the acid vinegars are. So with all the different products of the fruit—sham butters that pass for apple butter may be pumpkins or turnips or things of that kind—and others that are adulterated in the same way.

Q. Do you favor Federal legislation on this subject?—A. Yes; I do on the pure-food question.

Q. Where would you lodge the power to execute the pure-food law?—A. I think it ought to be lodged in the hands of the Bureau of Agriculture. Still, I might be wrong in that. Everybody is just as much interested as the farmer. I do not know but that might be utterly wrong. The Bureau of Justice, maybe, would be better.

Q. Have you a law in your State to prevent the spread of disease among domestic animals and fruits and plants?—A. We have one for domestic animals; it is very limited. We have none for plants or fruits.

Q. Do you favor such legislation?—A. Yes; I think there should be, both State and national.

Q. Now, you may give your reasons for favoring legislation of that character.—A. Unfortunately, in our county, along about 1895 or 1896 we discovered that the San Jose scale had been sent into our county. We could trace it to New Jersey, and it infested some 3 of the orchards there in our county. One of the worst was in the hands of a progressive farmer, and he has been constantly fighting it ever since, kept it in check, with no danger of spreading from his orchard, although he has not got it completely eradicated.

Q. (By Mr. PHILLIPS.) What kind of fruit?—A. In this case the one orchard was a pear orchard and the other was an apple orchard, and also a berry farm.

Q. The same scale affects all these kinds?—A. Yes.

Q. Does it affect cherries also?—A. Yes; all classes of fruit—plums and currant bushes were simply eaten up and destroyed with it. This one man utterly neglected his and the orchards all around him became infested with it. Now, if we had a law that would give some one the authority to come in and say to this man, "You have to destroy these trees," we could have eradicated it in the county and at a very slight cost. Now, we have it in about twenty localities in the county. This season, with the aid of our experiment station, the farmers held a meeting and subscribed funds to buy material to treat these orchards with. Some of these men were not able to get their own material, and we are spraying and applying all different remedies that are known to prevent it. But all this could have been obviated if there had been a law 10 years ago to prevent the sale of any nursery stock unless it had been, I will not say inspected, but fumigated, because to say that every tree would have to be inspected would take thousands and thousands of experts. For instance, a nursery that had, say 4,000,000 young trees in it, as it takes a microscopical examination to tell whether there is any scale present or not, you can see at once it would take a vast force. It would be a first-rate place for fellows who wanted jobs, because they would have to have hundreds of them. But they could be fumigated, and that would make it certain that we were not planting disease when we were planting the trees.

Q. Can they fumigate so as to destroy the scale?—A. Yes.

Q. What is the nature of it?—A. Hydrocyanic acid. They have to have airtight fumigation houses and they put the young trees in there for 10 or 15 or 20 minutes, and that destroys everything that is living.

Q. What method do you use in eradicating it where it obtains a hold in the orchard?—A. Of all the experiments we have tried we have decided that the best is crude petroleum right out of the ground. With us that is the most effectual and the least destructive to the trees of any. I have been advocating pure coal oil very largely in the past, for if it would not kill the scale, it would at least kill the tree for the careless fellow (laughter); but we find that the crude petroleum is the best remedy, according to our judgment, put on in the winter time.

Q. Spray them?—A. Yes; just cover it, have every bit of the tree thoroughly covered, and they will all be dead; but if there is one spot left on the tree untouched and there is a scale there it all has to be done over again the following season.

Q. It would require a very considerable amount to treat a large orchard?—A. Yes; it takes a great deal. Some of us have used as much as 20 barrels of it.

Q. (By Mr. A. L. HARRIS.) With good effect?—A. Yes. Of course we are experi-

menting, trying it out, and watching the results. I have been helping our experiment-station people with the experiments.

Q. Is the farmer affected in any way by large combinations of capital in the manufacturing industries?—A. We have found in the last 18 months that what is called the wire trust has been very much to our disadvantage. It has almost stopped fence building. We have gone largely into the wire fences on account of timber getting scarce, and the advance in price from 2 cents a pound up to 4½ cents seemed to almost entirely stop it.

Q. What kind of wire?—A. Barbed wire was coming to be the popular wire we used for fencing.

Q. Is that controlled by a patent?—A. I suppose there is a patent on that.

Q. (By Mr. PHILLIPS.) How is it in regard to nails?—A. Nails have advanced, but not quite as much as wire.

Q. Have farm implements advanced largely, too, in the last 18 months?—A. No. There is some difference, some advance, but not so largely as the wire. That was the greatest advance, the most unreasonable.

Q. (By Mr. A. L. HARRIS.) That was the barbed wire?—A. The barbed wire.

Q. Do you remember what brand you used in your locality?—A. We used what is known locally as the "hog wire"—regular buckthorn barbs on it.

Q. You do not remember the brand?—A. No; it is all controlled by the one company—the Gates.

Q. The American Wire Company?—A. Yes; the American Wire Company.

Q. (By Mr. CLARKE.) Does the price keep up?—A. Yes; it keeps up; and for the last 12 months I do not suppose there has been 5 tons come in. The people are simply letting it alone. It has dropped some now. They did take it up to 4½ cents a pound, but the price they are now trying to get is 3¼ cents; but the people are not buying at that.

Q. (By Mr. A. L. HARRIS.) What was the former price?—A. We got it by the ton at 2 cents, and 2½ cents for less than a ton.

Q. Was that at retail?—A. At ton rates it was 2 cents a pound. That was the lowest it came to.

Q. (By Mr. PHILLIPS.) Have there been any corresponding benefits come to the farmers from these combinations?—A. Not any that we can see.

Q. (By Mr. A. L. HARRIS.) If the farmer did not buy, what would be the effect on barbed-wire prices?—A. My impression is the farmers would have that in their own hands. If they would do away with our fence laws, that would do away with the wire trust as far as the barbed wire is concerned.

Q. (By Mr. FARQUHAR.) In other words, is it possible for the farmers to freeze out the trust?—A. Not all; possibly that one.

Q. I mean that one?—A. Yes.

Q. (By Mr. PHILLIPS.) Have you any law governing animals running at large in your State—domestic animals?—A. No; we have to depend on our fences.

Q. (By Mr. FARQUHAR.) I would like ask you again, what is your opinion of these experiment stations; are they quite beneficial to the farming interests, or do they give as many benefits as they cost?—A. I do not think that they come quite up to their cost. At present farmers are having a better feeling toward the experiment station than they did have a very short time ago.

Q. Do you know of any other plan that could be adopted by this Government to benefit the farming interests than through these experiment stations?—A. No; I do not know of any better.

Q. You could not reach the same benefits through such associations as the Grange?—A. No.

Q. Is it not really the only way they can reach scientific experiments—through these stations?—A. I think that is the only way.

Q. Are you not getting the advantage in West Virginia of the whole experiment stations of the United States?—A. Yes.

Q. (By Mr. A. L. HARRIS.) Does your station issue bulletins?—A. Yes.

Q. Are they pretty generally distributed among the farmers?—A. They are now. The reason I have said that the experiment station was more in sympathy with the farmers of late came from this fact: That since we have commenced to hold farmers' institutes through the State and the farmers have come out and come in actual contact—not the farmers, but the members of these stations' staffs—have gone out and come in actual contact with the farmers and found out what kind of experiments the farmers wanted conducted, and are getting their experiments up to suit the farmers instead of themselves, working on lines suggested by the board of agriculture, and so on, it is coming to give a great deal better satisfaction than it did, from the fact that now, when we have anything that goes wrong, disease breaks out among plants, or anything of the kind, these men will come right to the farm and conduct their experiments right there where everybody can see that

it is a general benefit. When it is conducted up in the laboratory you can not make the average farmer believe but what it is all tomfoolery. But now they are going out right among the people. That is why I say there is a far better feeling existing toward the experiment stations than there has been at any previous time.

Q. (By Mr. FARQUHAR.) In other words, you think there was among the old farmers an antipathy toward scientific farming?—A. Yes; no doubt about that.

Q. (By Mr. A. L. HARRIS.) Does your experiment station make experiments in the growing of grain?—A. Yes; that is, in the way of distributing new varieties and sending out certain varieties and quantities of fertilizers to be used, and suggesting different methods and having careful experiments made as to results. That is a practical way.

Q. That is beneficial?—A. Yes; no doubt about that being beneficial.

Q. Do they make like experiments in the growing of fruit?—A. Yes, in fruit growing. Both the panhandles of West Virginia, eastern and western, are the fruit sections, and in both the sections we are being guided a great deal by the experiment-station people in our experiments now in reference to the coddling moth and different kinds of spraying.

Q. Have you yourself been engaged in institute work in your State?—A. To a considerable extent during 1896 and 1897.

Q. What portion of your State did you work in?—A. I have been over as far as Greenbrier County and up about the mountainous parts of West Virginia, in the greatest part, about Upshur County and down about Marshall County and over in the eastern part—Jefferson, Berkeley, Hampshire, Morgan, and Mineral counties; have been at institutes in all these counties.

Q. From your observations, are the farmers in your State laboring under any disability that can be helped by legislation outside of the matter of taxation you spoke of a moment ago, either State or national?—A. Outside of taxes, I do not think there is any chance to relieve all the ills of the farmer by legislation.

Q. (By Mr. PHILLIPS.) Are you affected by discriminating freight rates?—A. We think we are. We sell our grain largely at Baltimore and find as a general thing that grain at Baltimore and Chicago is very near on a basis, and we never could understand how the Chicago fellow got his wheat over there at the same price that we got ours down there.

Q. (By Mr. FARQUHAR.) That is, the long haul was the same as the short haul?—A. Yes. They complain that that is not just, but I am not able to suggest a remedy.

Q. (By Mr. A. L. HARRIS.) From your observation what have you to say in regard to the conditions of those engaged in agriculture, as a rule, compared with former years?—A. In our State I think there has been a steady improvement.

Q. You have some hope, then, for the future of the farmer, have you?—A. Yes; I have every hope for the future, and I do not think there is any reason to doubt the future existence of the farmer. When he goes out of existence I do not know how about the other fellow.

Q. (By Mr. PHILLIPS.) You spoke of a discrimination in freight rates. As compared with Chicago what is the difference in distance from your section, of which you spoke?—A. Chicago, I think, is about 900 miles and we are 100 miles, and yet the rates are about the same.

Q. (By Mr. A. L. HARRIS.) Have you any competition in transportation?—A. We have two roads. The only place we can get any rates is where we do not have competition.

Q. A combination between the two roads?—A. Apparently so.

Q. To maintain freight rates?—A. To maintain rates. For instance, that is more with the express companies than the railroads. We have the Adams Express and the United States Express. There is no Adams Express Company at one station, but only the United States Express Company, and yet there they will give rates 10 cents lower on the crate—speaking in regard to fruit—than they will give us a few miles the other side where we have got competition. Sometimes we have hauled our fruit down there, 12 miles, to get the advantage of these rates.

Q. (By Mr. PHILLIPS.) That is expressage?—A. Yes; and from noncompeting points we have far better chances for rates than we have from competing points.

Q. (By Mr. CLARKE.) Why is that?—A. I suppose they make an arbitrary tariff for the two offices, and agree, that they will not fight one another in the matter of rates. They will drum for business, but will not under any consideration out rates where the two roads are in the same town.

Q. You and the other farmers there generally feel that the express rates are excessive and unreasonable?—A. Yes; that is the general opinion of everyone.

Q. When your fruit is carried by the express companies is it carried in refrigerator cars?—A. No.

Q. It is not really as well treated as it is by the railroad companies carrying it as freight?—A. No. It goes better as freight.

Q. Better and cheaper?—A. Yes. For instance, express goods will have to be handled the next day; refrigerator goods can be handled in a week.

Q. Have you ever made a careful study to learn whether or not it is more expensive to the express companies to handle it than it is to the railroad companies as freight?—A. No: I have never given it a careful study.

Q. They deliver it in less time, I suppose, is all?—A. That is all. Of course they will handle one crate for us, or a thousand, whereas if we ship in a refrigerator car we have got to have a carload.

Q. (By Mr. A. L. HARRIS.) Have you any trouble in getting refrigerator cars?—A. No; they furnish them wherever you order in time.

Q. (By Mr. CLARKE.) Is there a board of railroad commissioners in your State?—A. No. The only board we have nearest to that is the board of public works.

Q. Is that a State board?—A. Yes; consisting of the governor and several of the other members—

Q. (Interrupting.) Have they jurisdiction over the management of railways and express companies?—A. No; their only say is in regard to the valuations which shall be put upon the railroads for taxation purposes. That seems to be the only thing they have to do.

Q. Do you not think it would be a good plan to have a board of railroad commissioners in your State?—A. For what purpose?

Q. For the purpose of investigating questions of rates and accommodations to determine whether they are just and equal and fair.—A. Yes. If that board could be invested with power to remedy, I think it would be just right.

Q. (By Mr. FARQUHAR.) Have you not had legislative committees investigating there in the last 10 years? Have you not had several reports to your legislature as to excessive rates?—A. Yes. Every year in the governor's message and in everything else they complained about it.

Q. Yet you have no remedy in a State board?—A. No remedy whatever.

Q. You simply depend on the protests and pleas of the public that go to the legislature?—A. Yes. We have no remedy whatever. We think we are treated far worse on the express business than we are on the railroad business. For instance, a shipper in Baltimore could put his fruit into the Wheeling market, and he often does it, at 25 cents; and we, 100 miles closer, would have to pay 50 cents.

Q. (By Mr. CLARKE.) Are not the farmers in your State numerous enough so that you can elect a legislature which will try to remedy this inequality of which you complain?—A. No. The farmers generally control the legislature, but they always divide on political lines.

Q. That is the color line very often, is it not?—A. No; we have none of that in West Virginia. There are very few colored people in the State—very few.

Q. When you say political lines you mean on the lines of national politics?—A. Yes.

(Testimony closed.)

WASHINGTON, D. C., June 7, 1900.

TESTIMONY OF MR. WELLS W. MILLER,

Secretary Ohio State Board of Agriculture.

The commission met at 10.45 a. m., Vice-Chairman Phillips presiding. Mr. Wells W. Miller, secretary Ohio State Board of Agriculture, Columbus, Ohio, was introduced as a witness, and, being duly sworn, testified as follows:

Q. (By Mr. A. L. HARRIS.) You may state your name, your post-office address, and your occupation.—A. My name is Wells W. Miller; occupation, that of a farmer. My home address is Castalia, Erie County, Ohio. My business address at present is Columbus, Ohio.

Q. How long have you been a farmer?—A. I have been a farmer all my life, with the exception of 4 years spent in the Army and 3 or 4 years after that in mercantile pursuits.

Q. You may state what position, if any, you occupy in Ohio at the present time.—A. Secretary of agriculture.

Q. You may state, if you please, how the secretary of the State board of agriculture is chosen.—A. Shall I state in detail how we get our authority?

Q. I want to show how the members are chosen for office.—A. I can state briefly how the State board of agriculture is organized.

Q. Very well, you may do that. You may begin there.—A. The laws of the State of Ohio provide for the holding of county and district agricultural societies. By complying with the requirements of the law these county and district agricultural societies are entitled to send delegates, one each, to the annual meetings of the State board of agriculture which convenes in Columbus annually in January. These delegates from the different societies, together with the 10 members, constitute the State board of agriculture for the day on which the meeting is held. They select 10 members who constitute the board during the interim between the meetings. These are not necessarily members of county agricultural societies, but are generally, almost universally, prominent farmers from the different parts of the State. These 10 members who constitute the board elect such officers as in their judgment are required for the service of the board, and the rules of the board provide for the election of a president, vice-president, and treasurer from the membership of the board, and the secretary and assistant secretary, who may or may not be members of the board. At the present time they are not members of the board.

Q. You may state, if you will, what your duties are as secretary of the board.—A. The law of the State requires that the State board of agriculture shall hold annually a State fair or exposition. The statutes of Ohio also provide that the State board of agriculture, or its secretary more particularly, shall collect and publish agricultural and stock statistics of the State, both through a corps of volunteer reporters and through the township assessors and county auditors of the State. The law also requires that the State board of agriculture shall conduct farmers' institutes throughout the State. The law also requires that the secretary of the board shall be the inspector of all commercial fertilizers sold and used in the State. The secretary's duties are to see that all of these requirements of the law are complied with, under the general direction of the board, except so far as statistics and fertilizers are concerned, which are made the duty of the secretary and over which the board has no control.

Q. You may briefly outline, if you please, the farmers' institute work.—A. The farmers' institute work was begun in Ohio in 1880, the State board of agriculture making an allowance of \$1,000 to cover the expenses of lectures and organization. That was continued 2 or 3 years, and then gradually the appropriation was increased and the general assembly came to the aid of the board in increasing its allowance for the encouragement of agriculture, so that the board was enabled to devote from \$3,000 to \$5,000 to the institute work of the State up to 1890, when a general law was passed providing for a per capita allowance from the different counties in the State of 5 mills, 3 mills to be used for local expenses of such farmers' institutes as should be held in the county, and 2 mills to be available by the State board of agriculture for the payment of its share of the expenses in furnishing speakers and other expenses. This law was amended in 1896, making the per capita allowance from the county funds of the several counties 6 mills, with the provision that no county should pay more than \$250, so that the State board of agriculture is now in receipt of from \$60 to \$250 from each county in the State, and the local societies in receipt of an equal amount for expenditure at home. The aggregate is now about \$8,300 to the board, in round numbers, and an equal amount to the local societies of the State.

Q. What body composes these local societies?—A. They organize under the laws of the State and the rules of the State board of agriculture by petitioning the board—not less than 20 petitioners—and are granted authority by the State board of agriculture; and if, in the wisdom of the board, institutes shall be held under the direct auspices of the board, the institutes are held by the board or conducted by speakers furnished by the board, which makes available for local expenses one-half the per capita allowance; the lecturers are furnished by the board.

Q. Do you hold institutes in every county in the State?—A. Every county of the State, yes; from 1 to 4. The limit is 4 legally constituted or legally held meetings of 2 days each.

Q. What is the character of the work done at the institutes?—A. Education along agricultural lines. Our speakers are selected with a view to their capacity for educating with their lectures and bringing out interesting and valuable discussions among the farmers themselves. The best work we do, we think, is to encourage the spirit of investigation in the various localities more than the actual information imparted by the speakers. One of the principal requisites of a good speaker is to so outline his work as to bring to the front the best experience of a locality. We are surprised many times in finding the very best information in a locality that has felt the great need of farmers' institutes. Among its membership we have found some of our very brightest men and our best thought.

Q. Is this institute work conducted alone by gentlemen?—A. You mean the local end of it?

Q. Local end of it.—A. As to the local end of it, we are quite different from

any other State in that matter. We are very republican in that. We give the local societies a free hand to conduct their own institutes under certain regulations adopted by the board. Partisan questions must not be discussed, nor religious questions, but the work must be confined to the farm and its interest, and in that the local societies secure the assistance of some very estimable women, who present papers and deliver lectures. The State board of agriculture has not yet seen its way clear to employ women, although there is a call for them; but there are certain reasons, which perhaps it would not be necessary to discuss here, why we do not believe it would be wise to send out women by the State board of agriculture, as we are organized in Ohio. There are States so organized and who conduct their interest in such a manner that they can very well afford to have women on their list of lecturers, although somehow a scandal has obtained in one of the sister States, which we have studiously avoided, and perhaps are severely criticised because we have avoided it so rigidly.

Q. How many State lecturers do you send out?—A. We have on our list an average of 38.

Q. Do they discuss more than one subject?—A. Yes. They are necessarily obliged to have from 5 to 15 topics that they can discuss intelligently and interestingly, because each speaker is usually on for 5 lectures, and it would be very trying indeed if he would confine himself to one line, although the speakers have perhaps 2 or 3 topics that they can discuss more intelligently than more; but they divide their lectures so as not to have less than 5, and usually not more than 15.

Q. How many days of institute work is given to the session in the county?—A. Two days and one evening. Five sessions, a morning and afternoon and evening session, and morning and afternoon session on the second day, giving the speakers an opportunity to go on to the next appointment the second evening.

Q. In addition to the county, have you exercises at the capital on institute work?—A. Yes; we have at the capital what we term a State institute, continuing two days, just previous to the annual meeting of the State Board of Agriculture, which is the middle of January annually. There we have the best men available in the Union to deliver addresses, as well as our own people from our own corps of lecturers.

Q. Are the institutes in your State well patronized?—A. Very well patronized indeed. The average attendance is about 400.

Q. Is there a growing interest in the institute work?—A. Yes; it is growing remarkably; and we have applications for several times the number that we can grant, and many independent meetings are held under the rules of the board. Such aid is given to the local institutes as we are able to give, in the way of literature, documents, reports, etc., from the Department of Agriculture.

Q. You look upon the institute work as being valuable to the farmers?—A. Most valuable; increasingly so. Some of our farmers are being encouraged and their work is being made more systematic, and the wide range of discussion has been of untold value, I think, to the farmers of Ohio. I think, perhaps, I should state that the State board of agriculture furnishes 2 speakers to each institute; and they travel in pairs. Not more than a week, however, do any 2 of them work together. That is the only reason why we have not been able to supply female lecturers, because they are traveling over the State in pairs, and the 1 male lecturer and 1 female lecturer would not round up a good programme: while in other States they do the whole work from the institute bureau, sending out from 4 to 7 speakers, one who acts as president and another as secretary, conducting the whole meeting from beginning to close. They have in some States one or two women who lecture on domestic science, etc.

Q. Do you publish in your report any of the lectures delivered at the institutes?—A. Yes; we have a committee who select the best papers that are obtainable from the local speakers, as well as some from the employed speakers, and publish annually a full institute report, which is largely made up of the lectures delivered at the different institutes held in the State.

Q. Are those papers confined to the production of one sex only?—A. No, indeed; very many of our best papers are from women, and we have encouraged the employment of women by the local societies rather than by the board. They have an equal amount of money to use, and the board has always urged the local societies to encourage the women rather than to send women by the board, so that many women are on the programmes in the institutes of the State, but not sent by the State.

Q. How are those lectures printed and distributed?—A. We publish 10,000 copies for general distribution from the department of agriculture, sending to all agricultural societies in the State, all farmers' institute societies in the State, and all farmers' organizations in the State of which we have knowledge, and the

balance are held for distribution on request. Thousands of the farmers send in requests for them. Then this institute report goes into the general yearbook of the Department, of which 24,000 copies are printed, 19,000 of which are distributed by the members of the general assembly, 5,000 by the department of agriculture; but in practice many of the representatives from the larger cities do not care for their quota for distribution to their constituents, and they are made available for distribution by the department of agriculture, so that the department really distributes on an average 10,000 to 12,000 of the 24,000 annually.

Q. Is there an increasing demand for the report of the State board of agriculture, including these lectures?—A. Yes; there was a bill before the seventy-third general assembly, the object of which was to reorganize the publication of all such documents. The committee asked me for information, and I asked the committee to give the department 25,000 copies, because we had calls enough to distribute that number, against the 5,000 which are now by law available, reducing the number available by the members of the general assembly.

Q. What is the cost annually for the printing and binding?—A. I am not able to answer that, because it is done by the State on State contracts.

Q. Have you an idea as to the cost of the volumes?—A. No; I would rather not express an opinion about that.

Q. (By Mr. CLARKE.) In these institutes new and improved methods are discussed, I suppose, quite prominently?—A. Yes.

Q. Have you knowledge of the adoption of such methods in practice by farmers as a result of the agitation in institutes?—A. Oh, yes; that is brought to our attention almost daily. We have progressive farmers. Most of our lecturers are farmers. In addition to the farmers we have five of the professors in the agricultural college of the Ohio State University, and five of the station staff of the Ohio Agricultural Experiment Station. Those men are purely scientific.

Q. Is there cordial cooperation between your State department of agriculture and the National Department of Agriculture?—A. Entirely so; yes. However, there is not much cooperation. The laws have not been so framed as to make any considerable cooperation.

Q. Each department, then, works on independent lines?—A. Yes.

Q. But somewhat necessarily on substantially the same lines?—A. Somewhat; but it is true that there are no two State departments of agriculture similarly organized. We have, perhaps, the most complete department of agriculture, except one, in the United States, and that is Pennsylvania.

Q. Does your board of agriculture encourage the holding of local fairs or exhibitions?—A. Yes.

Q. And takes charge of them?—A. No; only in the matter of providing rules, which the board is authorized to do by the general assembly of the State. Those rules are in relation to the abuses and the general manner of conducting the exhibitions. For instance, the State board of agriculture does not allow any local society to have any objectionable features on the ground during the continuance of the fairs—no sale of intoxicants, no immoral exhibitions of any kind. In that connection, if it is proper here to state it, I will say each local society which is organized under the laws of the State and is operating under the rules of the board draws a per capita allowance from the county funds of their several counties, on the order of the president and secretary of the State board of agriculture. They are obliged to file with the board a statement under oath that all the rules have been complied with, and to make a full exhibit of all their transactions.

Q. The State itself does not make an appropriation for the aid of these local exhibitions, then, except by providing that they shall have a portion of the county funds?—A. No. The State has made very generous provision for the State board of agriculture, but not for the county societies.

Q. (By Mr. FARQUHAR.) Is horse racing in vogue at these county fairs?—A. Not horse racing that is understood to be horse racing at the county fair. The horse department is supposed to encourage the breeding of improved stock along all lines, and speed is one of the requisites of a driving animal, and they show the speed as well as the style and action of the animals; but no pool selling is allowed, or gambling, or other violations of the laws of the board. We have what are called county agricultural societies in our State which are separate and distinct from those organized under law, and which do not conform in any respect to the laws of the State.

Q. (By Mr. PHILLIPS.) In those are pool selling allowed?—A. Oh, yes. They are individual and separate organizations, over which the State board of agriculture has no control—seeks no control.

Q. (By Mr. FARQUHAR.) The county allowance does not contribute to the benefit of these fairs?—A. No.

Q. (By Mr. CLARKE.) How many years has your board been in existence?—A. Fifty-four.

Q. And from that time dates the beginning of scientific and progressive agriculture in your State, I suppose, largely?—A. Scarcely from that. Our records show that there were movements made in scientific agriculture as early as 1832 by a few prominent agriculturists of the State, but they had not unified their work so as to form a State organization until 1846, although they had made an effort for 2 or 3 years before that; but the State board of agriculture was organized in 1846.

Q. Has your board given a great deal of attention to drainage of land?—A. No, not a great deal.

Q. There is some need of that, I suppose, in different parts of your State?—A. Yes, but that has not grown out of the action of the State board of agriculture.

Q. Is it not necessary for farmers in considerable numbers, and sometimes even for townships, to cooperate to secure a suitable system of drainage?—A. Yes. We have very ample drainage laws in our State, which are executed by township trustees and county commissioners.

Q. Thus making it somewhat unnecessary for the board to engage in that work?—A. Only in an educational way. The board has from its organization published important and valuable papers and lectures on the subject of drainage, and still continues to do that, but it has taken no advanced position in that more than other societies, perhaps, and individuals not connected with the board.

Q. (By Mr. FARQUHAR.) Do you know what proportion of acreage there is of the swamp lands of Ohio? What is your general idea about it? Has not your State a good many, tens and hundreds of thousands of acres there, which by drainage could be reclaimed—fine land?—A. I do not think I would express an opinion on that. I do not think Ohio has so much of the unreclaimed land as other States. I do not know of a very large amount of it.

Q. (By Mr. A. L. HARRIS.) You spoke about the ditch laws. How general have those laws been availed of in portions of the State requiring drainage?—A. Very general; almost universal.

Q. You may state whether or not the State or the county in Ohio incurs any of the expenses of that improvement.—A. Yes; they incur a considerable part of the expense in paying the engineers, and of those employed, who are the commissioners, trustees, and engineers.

Q. How is the remainder of the expense paid?—A. By assessment, according to the benefits supposed to accrue.

Q. And the deferred payments—how is that arranged for?—A. By being placed on the tax duplicate, as other taxes.

Q. Money, for the time being, being raised by selling bonds?—A. Yes.

Q. And the property benefited taxed to pay those bonds?—A. Yes. In many cases the counties themselves, where the treasuries are in proper condition, pay the expenses of the improvement and collect on the tax duplicate as other taxes are paid, without the selling of bonds.

Q. You may state whether you have a similar law in Ohio in regard to road improvement.—A. Yes; general turnpike laws, and we have what is known as the 1 and 2 mile assessment.

Q. You may state, if you please, to what extent that law is availed of?—A. Very generally. We have a very considerable part of the State of Ohio improved under those laws—the roads improved under those laws; that is, in localities by counties, some counties of the State availing themselves while others do not.

Q. (By Mr. CLARKE.) If you recall the features of the law, will you kindly explain what this 1 mile and 2 mile system is?—A. By petition the matter is taken before the board of commissioners of the county or counties through which the improvement extends, and if the prayer of the petitioners is granted by the commissioners the improvement is made, similar in its details to the improvement of water courses, and the assessment is made according to the benefits within the 1 or 2 miles. We have two separate laws.

Q. Within the 1 or 2 miles on each side of the road?—A. Yes. In many cases the cities at the termini of the improvement are assessed a very considerable share of the expenses of improvement.

Q. Does the board of county commissioners make these assessments?—A. Yes, finally. I think very generally the assessments are made by the engineers and sometimes assessed by committees, but the final work is passed upon by the commissioners.

Q. To what extent have Telford or macadam roads been built in rural districts in Ohio?—A. It is difficult for me to give a very intelligent answer to that, because we have in some counties almost all the roads improved under the provisions of these laws, while in other counties where roads in the state of nature are passable,

are fairly good, the improvements have not been made. The result is that the counties which originally had the most impassable roads now have the best roads in the State.

Q. (By Mr. PHILLIPS.) You have no general system of macadamizing throughout the State; that is left to the local?—A. That is left to the local option.

Q. (By Mr. CLARKE.) Well, those roads you speak of as being very good are usually stone roads, are they not?—A. Yes; broken stone or gravel.

Q. Are there good deposits of gravel generally throughout the State available for road building?—A. Those deposits are not uniform over the State. Some counties have ample supplies, while others have none.

Q. Do the railroad companies of your State make any special rate on the transportation of road material?—A. I do not think they do. They transport a good deal of road material. I do not know that they make a special rate because of that. They make a very reasonable rate on road material, but I do not know that I could answer your question affirmatively.

Q. (By Mr. A. L. HARRIS.) Who bears the expense of the bridges and the culverting?—A. Anything more than \$50 is borne by the counties; less than \$50, by the townships, unless in case of an improvement. The bridges are added to the assessment sometimes, but not as a rule.

Q. Ordinarily, then, the land benefited pays for the grading and macadam or graveling of the road, and the county or township pays for the bridges and culverts?—A. Yes.

Q. (By Mr. CLARKE.) Is there any broad-tire law in the State?—A. On the improved roads; not on unimproved roads.

Q. Well, how do you make the distinction, because naturally if a farmer has a wagon he uses it on all roads, whether improved or not?—A. He is not allowed under the law to haul more than 2,500 pounds on a wagon of a given tread over an improved road; that is, on the road that is improved under the law just referred to.

Q. What has been the effect of that law in changing carriages?—A. It has had the effect of multiplying the broad-tread wagons very greatly.

Q. Is it found by experience that broad tires promote good roads and protect them—save them?—A. Unquestionably. There has been a growing friendship for broad-tread vehicles for 25 years.

Q. Are they better also for the farm roads?—A. Very much better. Very many farmers now have no narrow-tread wagons. I abandoned my last one a few weeks ago.

Q. You spoke a moment ago of the Ohio State University assisting your institute work in sending out lecturers. I wish you would state, if you please, briefly, whether you have in the Ohio State University an agricultural course.—A. Yes; we have an agricultural course in the college of agriculture. There are two or three courses, short and intermediate and long courses—I think three courses—as well as special, veterinary, and dairy and other special courses.

Q. Is there a degree conferred in taking either one of those courses?—A. Yes; in the full agricultural course, and in the veterinary, and I think in the dairy as well.

Q. Are those courses satisfactory to the agriculturists of the State?—A. I think so, very much more than they were a few years ago. A pretty general complaint went up against the State University, which is the successor of the old Agricultural and Mechanical College of the State, but recently the trustees and faculty have improved and enlarged the agricultural college so that I think it is now generally satisfactory to the people.

Q. It is well patronized—the agricultural department?—A. I would not think it well patronized for a State with the agricultural population that Ohio has, although it is growing in patronage and growing in the estimation of the agricultural public.

Q. Does the college give encouragement to that course of study?—A. Yes.

Q. The fault, then, is not on account of the college?—A. Not on account of the college, but more largely, I think, on account of the expenses. They have not yet reduced the expenses at the university to so low a point as they have at many of the other educational institutions in the State, therefore prohibiting or discouraging, at least, the attendance of the poorer class of farmers.

Q. What are those expenses; is it tuition?—A. Not so much tuition, but mostly board.

Q. Well, they give facilities for what we call "batching," do they not?—A. Yes; but not elaborate facilities.

Q. They have dormitory facilities?—A. They have dormitory facilities, but not extensive at all; really it has not been encouraged very much—not much attention given to that, not as much as to the educational features of the college.

Q. Those graduating at the college, do they go back to the farm as a rule?—A. Yes, as a rule.

Q. Is the State receiving valuable aid from that education?—A. Yes; some of very best lecturers and workers in agricultural lines, while they have returned to the farm, are from those graduates from the agricultural college.

Q. Is there any opportunity for employment on the university farm?—A. Yes; they pay a certain amount—15 cents an hour, I think—for such employment as they have for those students who seek it.

Q. Then the course could be made comparatively cheap?—A. Can be made comparatively cheap, and, in fact, some students have been self-supporting; but there is not that atmosphere there that there is in some of the other institutions.

Q. The classics overshadow the agricultural department?—A. Yes; undoubtedly.

Q. (By Mr. FARQUAR.) Well, is there not enough of the general educational curriculum there in the university itself to carry the farmer all through and yet at the same time attend these agricultural classes?—A. Many of them enter the agricultural classes for a year or two and then take up the scientific or classical courses—that is the tendency—and drift into professions or preparation for professions; but the gentleman asked me of those graduating in the agricultural college, about their returning to the farms. The greater number, perhaps, change their courses and finally graduate in one of the other departments.

Q. (By Mr. A. L. HARRIS.) You spoke also of the assistance given you by the experiment station. I wish you would state, in a brief way, to what extent the farmers have been benefited by the experiment station in Ohio.—A. The experiment station conducts experiments along the lines of crop production, fertilizers, and the study of the enemies to agriculture, and has given very much needed information along those lines. Like all other scientific people, they are criticised by those who are not given to scientific investigation; but the feeling and the cooperation and the mutual good work done by the experiment station to the farmers is very greatly increasing.

Q. Do they experiment in one part of the State only, or have they branch stations?—A. They have two branch stations—one in the northwest and one in the northeast—and the principal station is in the central part of the State, in Wayne County.

Q. Is it anyway connected with the agricultural college?—A. No.

Q. You are talking about experimenting in fertilizers. In what way is that experiment made?—A. By the application of fertilizers known as commercial fertilizers, and all fertilizers, in fact, on plats of ground on which are growing the different grains and products of the soil, and making very careful determinations and deductions, and publishing the same.

Q. How is that publication made and distributed?—A. By bulletins, and distributed to those who send in their names to be placed on the mailing list; or public men, prominent men, or men with whom the station staff is acquainted, furnish lists from different localities. All others can be placed on their list by personal application.

Q. Is that information pretty generally distributed?—A. Yes; pretty generally distributed.

Q. Has the station the franking privilege?—A. Yes; being under the auspices of the General Government, aided by the State government.

Q. Who makes your analyses of commercial fertilizers?—A. You mean the individual? I am charged with that duty. Not being a chemist, I employ a chemist in the Ohio State University, who is Prof. N. W. Lord, a man of national reputation, which is a very important factor with me in dealing with the manufacturers and consumers, standing between them.

Q. How is that report distributed?—A. Ten thousand of them are published annually and distributed, mostly by mail. It also is embodied in the annual report, of which there are 24,000 copies.

Q. Does that give the actual amount of different ingredients in different fertilizers in separate columns?—A. Yes.

Q. Of every fertilizer?—A. Every fertilizer in the State.

Q. How do you get your samples?—A. I have deputy inspectors of commercial fertilizers traveling the State all the time and securing samples from the open markets, not from the manufacturers. The law requires that manufacturers send in samples to the secretary when making application for license. Those are only used for comparison. The actual analyses are made from samples very carefully drawn from stocks of goods, supplies found on the markets of the State and in the hands of the consumers. My men visit every part of the State and gather samples from every possible source, so that the report shows the result of analysis of actual goods, which is very satisfactory to the consumer and entirely satisfactory to the honest manufacturer and dealer and not satisfactory to the other man.

Q. You speak of the fertilizing law. Will you state briefly the provision of that law and the penalties attached?—A. The law provides that the manufacturers and dealers in commercial fertilizers shall, between the 1st of January and the 1st of May, annually, make application for license and pay fees for the privilege of selling and offering for sale in the State of Ohio. Twenty dollars per brand is the fee. If the application is correct in form, the license is issued by the secretary of the State board of agriculture for a year ending with the calendar year, December 31. They are obliged to affix to each and every package sold or offered for sale the fertilizing ingredients, the amount of nitrogen, or its equivalent in ammonia, phosphoric acid, and potash; and a violation of the law in not properly stamping or stenciling or marking their goods, or having less fertilizing ingredients than they claim greater than 1 per cent, subjects them to a fine of from \$200 to \$500 and to imprisonment not more than 30 days.

Q. Have you had any prosecutions or convictions under that law?—A. No convictions, but several prosecutions; but before the matter got far enough to have a conviction, they have in every case paid the penalty and promised to be good, and there have been no convictions.

Q. Is the law satisfactory to both the manufacturer and the consumer?—A. I think fairly satisfactory to the consumer. The law is not perhaps absolutely unsatisfactory to the manufacturer, but its enforcement has been unsatisfactory. But I think now it is very satisfactory.

Q. Do you collect data in your office as to the amount and value of the fertilizer used in the State?—A. Yes; through the township assessors and county auditors.

Q. Have you in mind the amount that was used, say, last year in Ohio?—A. Our records are evidently greatly at fault in that. They show about 75,000 tons, while private investigations on my own account with dealers and manufacturers established to my satisfaction the fact that in 1899 there were sold and consumed in Ohio fully 200,000 tons.

Q. Have you in mind the average cost to the farmer per ton?—A. About \$17.

Q. It would seem then to be pretty generally used in Ohio?—A. Very largely used in some sections, and in some other sections but very little.

Q. Is the demand growing from year to year?—A. Yes. Three years ago, in 1896, my estimate was 150,000 tons, so that if I am correct the increase has been or was 33½ per cent in 3 years.

Q. (By Mr. FARQUHAR.) In what section of the United States are these fertilizers mainly manufactured?—A. The sources of supply are mainly in the West—for the animal supply—Chicago, Omaha, and Kansas City; and of the mineral supply, from Florida, South Carolina, and Tennessee, while the potash comes wholly from Germany. It is manufactured all over the United States, but on the seacoast more largely than any other particular part of the United States. The next perhaps would be the cattle centers, or the cattle center, we would say, Chicago.

Q. Comes from the slaughterhouses and the condemned cattle?—A. Yes.

Q. Has there been much difference in the price of fertilizer in the past 5 years in Ohio?—A. No; not a very marked difference; a little increase last year on certain ingredients. The phosphates have been growing a little lower because of the enlarged territory from which phosphates are derived—that is, mineral phosphates.

Q. (By Mr. A. L. HARRIS.) I suppose you are acquainted with the subject of taxation of farm property in Ohio, of course?—A. Somewhat.

Q. I wish you would outline the method of taxation in Ohio and say whether or not the agriculturist has to bear more than his share of the burden of taxation.—A. The laws of the State require that all property shall be taxed at its actual value. The values for taxation are fixed by township and district assessors. The property owned by agriculturists is assessed the same as other visible property—at its true value—as provided by law. Still I believe it is generally understood that it is not placed on the duplicate for all that it would bring under the most favorable conditions of sale. I have no doubt that the farmers of the State of Ohio are paying an undue proportion of taxes, because of the fact that securities are not taxed at their full value, or, in other words, they are not placed upon the tax list. What the farmer has is visible. It is not, I think, due to any superior integrity or honesty on the part of the farmer, but to the fact that his property is exposed to view and can not possibly escape the assessor's eye, while stocks and bonds, moneys and credits can and do. In the law itself, if it could be enforced, I see no reason why the farmers should complain.

Q. Would there be any advantage in appointing instead of electing the assessors?—A. If they would appoint excellent men, it would be a great advantage to have them appointed, because men who are elected as assessors are like all other officers who are elected—small officers—paid very small incomes and greatly inclined to favor the voters of their respective districts.

Q. (By Mr. FARQUHAR.) Does politics enter into the work of the assessor—favoritism?—A. Favoritism; yes.

Q. Do you desire to make the claim of venality among the assessors?—A. No; only that there are some very incompetent men elected assessors in Ohio, and I think there is no doubt that they favor their friends sometimes.

Q. Is it an office that there is much renomination in—reelection?—A. Yes.

Q. So that you are apt to have a continuance of the same one that is in the office?—A. Yes.

Q. What is your means of appeals against the assessors?—A. Appeal to the board of equalization of the county.

Q. In many cases is it successful?—A. Not many compared to the whole.

Q. Consequently they feel discouraged and make no appeal?—A. Make no appeal as a general rule.

Q. (By Mr. A. L. HARRIS.) How often is your real estate assessed?—A. Once in 10 years.

Q. How often is your personal property assessed?—A. Annually.

Q. Is there frequently a disposition on the part of the owner of intangible property to avoid the questions of the assessor?—A. Unquestionably; and many refuse to answer at all.

Q. (By Mr. PHILLIPS.) What do they do if they do not answer?—A. The assessor makes such return as he can from the information he can secure and adds 50 per cent to it as a penalty; and many people, owners of intangible property, let this stand.

Q. The most of them do, do they not?—A. Yes.

Q. (By Mr. A. L. HARRIS.) Have you any idea of the value of intangible property that never finds its way to the duplicate in Ohio? Was there a tax commission appointed a few years ago to investigate that subject in Ohio?—A. Yes.

Q. Do you remember what their general finding was in that respect?—A. Why, that there was a very considerable part of the intangible property that was not placed on the tax rolls.

Q. (By Mr. PHILLIPS.) Was it considered that the 50 per cent would account for that, added to their own estimate—the estimate of the assessor?—A. Well, I could only answer that by supposing that it was when it was enacted. That is an old law.

Q. (By Mr. FARQUHAR.) Under the taxing law of your State has the taxpayer an opportunity to swear off his tax?—A. Yes; Many times where the tax is placed, where the returns are made by the assessor and the 50 per cent added, or even where the 50 per cent is not added, the owner of the property comes in and makes an affidavit that it is too high, and makes his own returns, which is in many cases accepted.

Q. That is, really the whole end of the matter of taxation depends on the swearing off by the taxpayer?—A. That is the end at that time, but for a few years past we have had what is known as the Tax Inquisitor Law. The counties are authorized to employ a man whose duty it is, or whose privilege it is, at least, to investigate on his own account the holdings of the citizens of the county, and if he finds that they have been escaping taxation he reports to the auditor the amount, and the matter is investigated, even though settled previously, and large amounts of property have been discovered through these inquisitors.

Q. Well, these inquisitors then are officers under your auditor of State?—A. Auditor of the county.

Q. Auditors of the counties?—A. Yes; county auditors.

Q. You have no State inspection, have you, of your taxes?—A. No; we have a State board of equalization. I think no State inspection.

Q. Do you not think that where there are claims of tax shirking in any locality in Ohio or elsewhere, that the public prosecutor, if he is attentive to his business, under the proper law could make all tax shirkers pay in time? Is it not the laxity in the execution of the law that is the trouble?—A. That is the trouble.

Q. The innocent party must pay for those who shirk?—A. For those who shirk; that is correct.

Q. And that it is proper and just that the State government or county should protect the innocent taxpayer from the shirker?—A. Yes.

Q. Is not that the remedy really that should apply in every county and every State?—A. I think that will cover the trouble if it could be properly done.

Q. And you believe that in the tangible property of the farmer there he stands a harder task with the assessor than those that have intangible property that shirk?—A. I have no doubt of it.

Q. And, on the other hand, those that have intangible property can more readily pay taxes than those that have tangible?—A. Yes.

Q. Consequently it is a positive injury to the taxpayers of the county?—A. The

owners of the intangible property actually own their property, while the man who pays the taxes on his real estate is paying for the privilege of calling it his own at some future time.

Q. (By Mr. A. L. HARRIS.) How do you assess the value of corporations, especially railroad corporations, in your State?—A. By a board composed of the county auditors through which a given railroad extends. Their practice is to assess the company so much per mile for the main track, so much a mile for side tracks, so much for termini and improvements, and so much per mile for rolling stock.

Q. (By Mr. PHILLIPS.) Do you consider that a satisfactory way of taxing railroads?—A. I don't think it is an equitable way as it is conducted.

Q. You then favor a general law in the State in regard to taxing the railroads?—A. Yes.

Q. Rather than a local?—A. Yes.

Q. (By Mr. A. L. HARRIS.) Have you any amendment to the present law that you would care to suggest?—A. Oh, I do not know that I have. It is a matter to which I have given no attention for the last several years.

Q. You are conversant with the law known as the Nichols law?—A. Yes.

Q. If applied to railroads, what effect would that have in assessing at the true value in money the railroads?—A. I think it will be very much more successful than the law that we are now operating under.

Q. You feel like recommending the Nichols law as an improvement?—A. Yes.

Q. Have you any other suggestions to make as to the amendment of the tax laws of Ohio either for individuals or for corporations?—A. I think that all property should be assessed according to its earning capacity—intangible property, stocks, and bonds. I think that the constitution of the State of Ohio should be so amended as to make it legal to impose a license or collect a license or control the sale of intoxicants.

Q. (By Mr. FARQUHAR.) Somewhat after the character of the Raines law in New York?—A. Yes; something of that kind.

Q. Do you mean so that by such a thing as the Raines law you could get a great deal larger revenue than you can now, or would it have some public virtue features?—A. I think we would have a more responsible class of people in the business of selling intoxicants and that it could be better controlled; and yes, if you please, a larger revenue would be received because the business adds greatly to the burdens of the people of the State. I think the Raines law in New York, however, is more abused. Perhaps a better license law need not be.

Q. (By Mr. CLARKE.) Have you any knowledge as to the drinking habits of farmers in Ohio compared now with former years and compared also with men in other occupations?—A. Oh, I could only express an opinion.

Q. Are you willing to give an opinion?—A. Yes. I think the drink habit is not as great now among the farmers—in fact, among any class of citizens of Ohio—as it was some years ago. There are farmers and farmers, but I think what should be considered farmers are not as a rule intemperate, and I think intemperance is not as general as it was some years ago.

Q. Is it customary with Ohio farmers generally to furnish any kind of spirituous or fermented liquors in the field?—A. Not among the American farmers—that is, American by birth. The Germans in some localities have beer; but that is not as general as it was 10 years ago.

Q. (By Mr. A. L. HARRIS.) Have you any organization of farmers in Ohio that discusses these tax questions as well as other questions pertaining to agriculture?—A. Yes; we have various farmers' organizations. The leading one, perhaps, in numbers and influence is the grange, the Patrons of Husbandry. We have in the State a good many farmers' clubs who discuss—these organizations discuss all these questions.

Q. Has any remedy ever been agreed upon by any of the farmers' organizations and presented to the legislature for relief on the subject of taxation?—A. Not agreed upon, no; except that the farmers' organizations very generally believe that franchises and intangible property should be placed on the tax duplicate at their actual value; but they have not agreed upon any formal legislation.

Q. Does the constitution in Ohio interfere in any way with the taxation of franchises proper?—A. It is supposed to.

Q. Has any effort been made to amend the constitution in that particular in the State?—A. Yes.

Q. What has been the result?—A. It has not been successful.

Q. Can you state briefly the provision of the amendment?—A. I think I would rather not undertake that.

Q. On the subject of corporations, please state whether or not there is any complaint among the farmers in regard to discriminations or high rates of fare or transportation of farm products?—A. Yes; that complaint is pretty general.

Q. Has the matter ever been brought to your attention sufficiently that you could give the commission a remedy?—A. No; I think I have not any remedy to suggest.

Q. You have a railroad commissioner in Ohio, have you?—A. Yes.

Q. For railroads and telegraphs?—A. Yes.

Q. Does he from time to time lay before the governor of the State his reports upon the subject of railroads and telegraphs?—A. Yes.

Q. Do you remember whether or not he has recommended any legislation along these lines?—A. No; I have not had any definite information.

Q. The matter has been agitated, has it?—A. Very greatly.

Q. For legislation?—A. Yes.

Q. Has there been any decline in the money value of farm lands in Ohio in the last 20 or 30 years?—A. Yes; in the last 25 years there has been a marked decline in the value of farm land.

Q. Is there an up grade at the present time?—A. I think there is. Not so much so in actual sales as in the confidence of the people generally—the owners—and there are fewer forced sales than there were several years ago.

Q. Was that decline in the value owing to a decline in the actual productive quality of the soil or from outside causes?—A. The actual productive quality of the soil is greater than it was.

Q. How has that decline in values been brought about?—A. I think two principal causes: One is the appreciation of value of money; and the other the competition of the great West, which has been so greatly opened up in the last quarter of a century.

Q. (By Mr. PHILLIPS.) You think that is the cause largely of the decline in the value of farming lands?—A. Yes; farm values in the Eastern States (New England and New York State) have depreciated much more than Ohio values have. I think that is largely because of the competition. They have suffered more from competition even than we have in Ohio.

Q. Well, are farm lands now higher than they were before the war of the rebellion—the civil war—or was the war a factor in the enhancing of the value of land for a time?—A. The war was a factor, but land to-day is principally worth more than it was before the war, because of the greatly increased betterments.

Q. Will it sell for more per acre now than it did immediately before the war?—A. I was trying to give an answer to that. You mean in the same condition?

Q. Yes.—A. In the same state of improvement?

Q. Yes, certainly; that would have to be ascertained, to ascertain the value at different times—both.—A. So far as my knowledge goes, I should say yes.

Q. That it is worth more now than it was at that time?—A. Yes.

Q. Then, immediately after the close of the war was there a very considerable advance in the price of land?—A. A very considerable advance during and immediately after the war.

Q. Had the money values anything to do with that?—A. I think very greatly.

Q. It began, then, to be settled more after we returned to specie payment?—A. Yes.

Q. Then the war was the cause, in a sense, for the advance in the price; the money conditions, in a sense, growing out of the war?—A. Yes; the money conditions growing out of the war had much, I think, to do with the increase of the value of the agricultural property of the State.

Q. (By Mr. A. L. HARRIS.) Did the increased demand for agricultural products immediately after the war have any effect on the price of farm products?—A. Undoubtedly it did, very greatly.

Q. Did it have any effect on the price of farming land?—A. Oh, yes.

Q. (By Mr. FARQUHAR.) Taken all in all, do you think the condition of the farmer before the war and his present condition are much the same?—A. No; I think he is now in a much better condition than he was before.

Q. (By Mr. CLARKE.) Are there any abandoned farms in Ohio?—A. No; I have yet to hear of one. I think the farmer complains now because he feels that he is not as prosperous as he was at a given period after the war. I am explaining my answer to the question just asked about the relative condition of the farmer before the war and at the present time. I think that the condition of the farmer at the present time is greatly better than it was before the war.

Q. (By Mr. FARQUHAR.) Do you think at the present time the farmer is in just as good condition as the merchants and manufacturers in your villages and cities, all things considered?—A. I think for a period of years his condition was as good. At this particular moment I think it is perhaps not as good. The conditions are very favorable to the manufacturer and dealer in villages and cities at the present time, and the conditions in Ohio are very unfavorable to the farmer at the present time.

Q. To what do you attribute this unfavorable condition of the farmer?—A. Oh, the loss of crops in the present year, and to the low prices prevailing for some of the products of the soil at the present time, and the exceedingly favorable condition under which the city business man is now conducting business. All of the merchandise has appreciated very greatly in value, which causes the farmer to pay a larger price for his necessities and the merchant is getting a better profit.

Q. Well, has not wool appreciated, too, in the meantime?—A. Yes.

Q. And have not meats appreciated in the meantime?—A. Yes.

Q. (By Mr. PHILLIPS.) What has caused this great advance in the prices of merchandise and manufactured articles recently?—A. Well, I think there are some natural causes, and I think there are some artificial causes. The trusts have much to do with the increase in values of some of the merchandise, and the conditions prevailing throughout the country have had much to do with it.

Q. The reaction from the panic you think had something to do with it, and the demand for more manufacturing on account of less production?—A. The stocks had been exhausted; and there seems to be a demand for more than the mills could furnish, and the price appreciated.

Q. By Mr. CLARKE.) Have you any knowledge as to whether or not prices were too low during the period of depression?—A. From general knowledge I believe they were too low.

Q. Some appreciation, therefore, has been just and desirable?—A. Yes; but it has gone to the extreme and gone too high, as is usually the case; and is now, I think, settling back somewhat to normal conditions.

Q. (By Mr. A. L. HARRIS.) You may state whether or not any of the articles that are manufactured by large industrial combinations are used by the farmers; and, if so, what are they, and to what extent—fencing, roofing, or anything of that kind?—A. Well, anything of an iron or steel nature—that is, manufactured from iron and steel—has been greatly appreciated, in some cases more than 100 per cent, and merchandise generally which the farmers are under the necessity of buying has greatly appreciated and all building material.

Q. (By Mr. PHILLIPS.) Including lumber?—A. Including lumber. Lumber is about 25 per cent higher than it was.

Q. What is the per cent of increase on nails and wire fencing?—A. It was 100 per cent; it is now perhaps 75.

Q. The farmers' products have not advanced in proportion to this?—A. Not advanced in proportion. There are some lines of farm products that have advanced, notably wool and meat products, but they do not affect all farmers. Comparatively few farmers in Ohio have wool and beef to sell.

Q. (By Mr. CLARKE.) Are not the present prices of wire fencing of various kinds and also of nails and tin plate lower than they were 10 years ago?—A. I think I can not answer that question; I am not certain.

Q. Your comparisons, therefore, are with the period of depression?—A. Yes; with the low prices. I know that the low prices are very much lower than they were 10 years ago; but I am not able to answer your question.

Q. (By Mr. A. L. HARRIS.) Are the farmers of Ohio protected by any stock law or fence law, so that they can do without the use of wire for fencing?—A. They are not obliged to fence at all. It is a matter of choice with them whether they do or do not use fences.

Q. Is there a possibility, then, so far as wire for fencing is concerned, that the farmer may be able to do without until the price comes down to the proper figure?—A. I do not think they will use as much as they would if prices were lower, but I do not think the farmers in Ohio will ever dispense with fences. They have been educated from generation to generation to the habit of fencing their farms and fields, and I think they will so continue, although in some localities it is a growing practice to discontinue the building of fences.

Q. (By Mr. PHILLIPS.) Are domestic animals permitted to roam at large in your State?—A. No; only as many other things are permitted in violation of law. I suppose you refer to the law?

Q. Yes; whether there is a law prohibiting that?—A. Yes.

Q. (By Mr. A. L. HARRIS.) Do you know of any combinations to control the prices of farm products, such as dealing in options and futures?—A. Yes; I know of them in a general way.

Q. What have you to say in regard to their effect upon prices of farm products, if any?—A. I say that at times there is no doubt that values are enhanced or depreciated, but for all time or for the average time, if you please, I am not prepared to say that they affect injuriously the interests of the farmer.

Q. It is only temporary, you think?—A. Yes.

Q. Have you any means of gathering statistics in Ohio as to grain and stock conditions?—A. Yes; we have a very complete system of gathering statistics.

Q. Are those sent out to the public?—A. Yes.

Q. Does that have any effect so far as prices settling back to their normal condition?—A. Yes; there is a very great demand for our monthly reports. They are considered by all the dealers as being very valuable and worthy of consideration. They take every opportunity to try to get them at the earliest practical moment, and prices are at times affected by these reports.

Q. But in the main supply and demand regulate the price?—A. That is my opinion. I think that is not the opinion, however, generally of the farmers of the State.

Q. Admitting that that condition exists—that the farmer is laboring under a disability, have you any remedies to suggest or have they discussed a remedy that you think is available?—A. No.

Q. Have you ever given any consideration to what is known as the Hatch law, to tax? Would you care to express an opinion upon that principle of controlling dealing in options and futures?—A. I have never had any particular confidence in it. As I say, I am perhaps not representing the average agriculturalist of the State in saying this, but this is my personal belief, that it is not a crying evil that we need to pay any very serious attention to.

Q. Do you know whether freight rates have increased any in the last year?—A. Yes; they have.

Q. Do you know what per cent?—A. No.

Q. What effect does that have upon the farmer?—A. It has the effect of reducing the value of his products at their markets. I think much more can be accomplished in the management of transportation than in the matter of dealing in options for the benefit of the farmer.

Q. (By Mr. PHILLIPS.) Can you ship farm products from Ohio east as cheaply as from Chicago, or more cheaply than they do from Chicago?—A. No. I will say this, that the people who live 50 and 100 miles east of Toledo are under the necessity of paying the freight to Toledo and from Toledo to New York. They are obliged to pay the freight from their homes to Toledo, in addition to the Toledo rate to New York, to ship their products to the seaboard.

Q. Is the Toledo rate cheaper than the Chicago rate?—A. I think it is, slightly. I am not prepared to say that the rate in Ohio is greater than the Chicago rate, but it is greater in the eastern part of Ohio than it is in Toledo.

Q. That would be one reason why your farm products are not so valuable in Ohio as they would be if you had equal rates?—A. Yes. The same in the West. And another reason is the great increase in production in the West that I referred to a little while ago in reference to the depreciation of farm values.

Q. About what would be the difference, say, from the central part of Ohio to New York, and from Chicago to New York, in distance?—A. About 300 miles.

Q. And yet, in your opinion, you pay from the central part of Ohio about as much as they do from Chicago?—A. From Chicago; yes.

Q. (By Mr. FARQUHAR.) Are you taking into account the export cereals, or is it the domestic consumption you are talking about when you speak of rates—through export rates in comparison with domestic rates?—A. I was taking into account both of them.

Q. Well, your export rates from Toledo—rates to Liverpool on cereals—are you comparing those with the Chicago rates?—A. I am not certain; I said I could not answer about Chicago.

Q. (By Mr. A. L. HARRIS.) Do you know whether the shippers in the interior points in Ohio ever have any trouble to get cars in busy seasons?—A. They do.

Q. Does that work to the advantage or disadvantage of the farmer?—A. Disadvantage, clearly. Very much of the cereal products of Ohio are shipped west before they are started east.

Q. (By Mr. CLARKE.) How far west?—A. As far as Toledo.

Q. That is a through billing, is it not?—A. Yes.

Q. Would it be advantageous to require the railroads to make all their stations through billing points?—A. Well, no, I think not; not all the smaller ones.

Q. (By Mr. FARQUHAR.) You speak of the farmer paying this extra freight. Is it common for the farmers of Ohio to ship their grain to New York or any seaport, or is that done by commission men?—A. That is done almost entirely by commission men.

Q. So that the farmer gets the going rate for his grain where it is sold?—A. Yes.

Q. (By Mr. A. L. HARRIS.) But does not the buyer often take more than is necessary sometimes in order to provide against the contingency of the obstacles he has to overcome—the merchant?—A. Yes. They make no secret of that in some cases; they say so openly, that they have to protect themselves in that way because of the possibility of their being held up.

Q. (By Mr. FARQUHAR.) But has not your Ohio farmer got an advantage now,

with the purchaser right on the spot, ready cash, immediate on delivery, and the going rate of the market gauged either by Chicago, or New York, or Liverpool, over what he ever had before. Has he not got more chances for fair play now for the products that he has for sale than he ever had?—A. I do not think his condition is worse now than it was.

Q. Well, when you had to sell to the storekeeper in the early days, do you think the farmer had any advantage at all? Was it not all on the side of the storekeeper, the merchant?—A. Oh, no. I am not inclined to be a calamity howler. I am inclined to think the farmers are in a very good condition. Being a farmer myself, I think they have evils of which they can justly complain.

Q. Well, if there is a discriminating rate, is not the cut shared by the consumer with respect to that extra discrimination, and not altogether lost by the farmer or the commission man? Does it not come on the consumer finally?—A. Well, that is a very large subject. Where values are established, we have plenty of economists that claim they are always valued at Liverpool, and they make a very fine argument that if we had an export bounty we would increase the value of the home products by the amount of the export bounty; that all prices come from Liverpool. I do not believe that. I believe that all the conditions all over the world make the prices at Liverpool, and then we locally are averaged up from Liverpool.

Q. And very often you have to sell under the conditions of a gambling market in Chicago or New York?—A. Very often; and sometimes, if you please, under the favorable conditions of a gambling market.

Q. So that sometimes it is European consumption that enters into it, sometimes bad weather, bad crops, insects, blight, and anything else that enters as much into it as the Liverpool prices?—A. These things all help Liverpool make prices, and the weakness of human nature makes prices fluctuate many times quite as much as natural conditions; and the farmer does not always get the hot end of it.

Q. (By Mr. A. L. HARRIS.) Can the farmer produce cheaper now than he could 25 or 30 years ago?—A. Yes, by reason of improved machinery and appliances.

Q. Does the farmer use as much hired help now as in former years?—A. No.

Q. Is there a demand for help in the rural districts?—A. I think so, yes.

Q. Has the price for farm help increased or decreased in the last 25 or 30 years, per day or month?—A. Compared with 30 years ago it has perhaps not increased, but compared with 40 years ago it has greatly increased.

Q. Thirty years ago we were coming out of an abnormal condition?—A. The abnormal condition succeeding the war.

Q. Have you a pure-food law in Ohio?—A. Yes.

Q. How does that work—for the benefit of the community or detrimental to the community?—A. I think so far as it is enforced it is beneficial.

Q. State whether or not it is enforced generally in Ohio.—A. To some extent.

Q. Is it a difficult law to enforce?—A. I think it is a very difficult law to enforce.

Q. (By Mr. PHILLIPS.) Do you consider your pure-food law as good as that obtaining in other States, or have you made some comparison?—A. I have not given any great attention to that, but I think we have a fairly good pure food law in Ohio.

Q. (By Mr. A. L. HARRIS.) It is enforced by the food and dairy commissioner?

A. A food and dairy commissioner, elected by the electors of the State.

Q. Who appoints assistants in different portions of the State?—A. Yes.

Q. Have you given the subject of a national pure-food law any thought?—A. Some thought; not extensively.

Q. Are you favorable to it?—A. I am favorable to such a law and I believe that is where we should have the legislation.

Q. Where would you lodge the enforcement of that law?—A. In the department of agriculture.

Q. Have you considered or examined the provisions of some of the pending bills before Congress, and those that have been before Congress heretofore?—A. Not to any great extent, but their general features.

Q. As a general thing you favor the proposition?—A. Yes.

Q. Have you a law in Ohio to prevent the spread of disease among animals and plants?—A. Both; yes.

Q. Who enforces the law to prevent the spread of disease among animals?—A. I think it is not very rigidly enforced.

Q. You have a commission?—A. Yes.

Q. The enforcement, you think, might be improved upon?—A. I think so.

Q. Is that commission paid a sufficient salary to look after?—A. (Interrupting.) I think the commission is not paid a salary. I think the 8 members of the commission receive only expenses, and they employ experts, men that conduct experiments.

Q. Is that entirely separate from your department?—A. Yes; it is called the live-stock commission of the State; is composed of 3 members appointed by the governor. It is in such repute now that I am informed that the general assembly made no provision for its existence for the succeeding 2 years—for this and next year.

Q. Have you ever thought of any amendment to the statute of Ohio that would make that law more efficient?—A. Yes. I prepared a bill two years ago which passed the senate and would have passed the house except for unfortunate differences existing between some of the members growing out of some legislation sought for one of the large cities of the State, so that it was not favorably acted upon in the house. It provided that the state board of agriculture should constitute the live stock commission of the State with authority to appoint such officers as it deemed necessary, using very largely the present law of the State. That is what ought to have been done because our board is representative of the different parts of the State and is always composed of very good material. I had in mind then the appointment of a State veterinarian with office in the department of agriculture who would be ready at all times to respond to any calls from the different parts of the State, and that matter would grow into a very considerable bureau of the department of agriculture. The principal officer of the present board is a physician with a large city practice, and I think he is not particularly interested in the work of the commission. The members of the commission are very estimable gentlemen, but the commission itself is not valuable to the farmers of the State.

Q. Have you examined the national law relative to the prevention of the spread of disease among domestic animals?—A. Yes.

Q. Have you any suggestions to make as to any amendments that could be made to that law?—A. It is mostly prohibitive as to transportation. No. That is very good. The national law also provides for the cooperation by the Bureau of Animal Industry of the United States Government with State live stock commissions where they are organized for cooperation, which ours at present is not, and which we sought in the legislature two years ago.

Q. So to some extent you lose advantage of the Federal law?—A. Almost entirely.

Q. (By Mr. FARQUHAR.) Does not the Federal law establish a quarantine for your protection?—A. Yes; that is largely its province now.

Q. It is all of its province, in fact?—A. No; not all.

Q. Almost; of course condemnation enters into it.—A. The national law provides for cooperation with State commissions in the matter of investigation and the extirpation of diseases, etc. The expense is borne by the National Government, and would be a very great aid to the commission if enabled to cooperate. I think we have perhaps as poor enforcement of live stock laws in Ohio as in any State.

Q. (By Mr. A. L. HARRIS.) They make reports from time to time?—A. Yes. Don't ask me about the reports, Governor; I suppose you have seen them.

Q. Have you a law in your State to prevent the spread of disease among plants, fruit trees, etc.?—A. Yes; they are working on that legislation now. They have had some laws in regard to that matter for some years, and this year quite an important addition is made to the laws for the suppression and eradication of the San Jose scale and other insect pests.

Q. Have you any amendments to suggest to that law further than those put on the statute book by the present general assembly?—A. I think that I have not at the present moment, but I had during the discussion in the general assembly. I thought they ought to add a good deal to it; but they are going in the right direction. They have appropriated \$15,000 and placed the matter in the hands of the board of control of the agricultural experiment station, and the board has appointed an inspector who will inspect the nurseries and orchards of the State, and I think that from that will grow a very good law.

Q. Have you any suggestion to make on your own account for the improvement of the condition of agriculturists in your State or in your locality?—A. Nothing, except as to the more equitable enforcement of the tax laws and the transportation of products. I believe farmers have the same interests that other people have.

Q. The question of transportation is almost necessarily one of Federal legislation?—A. I think so.

Q. Are you in favor of Federal control of our lines of transportation?—A. No, except so far as rates are concerned—not ownership.

Q. Have you any suggestion to make as to the best means for the Federal Government to control as to rates?—A. Nothing more than your commission has already

recommended, that the Interstate Commerce Commission's powers should be increased and enlarged and that they have better facilities for enforcing their orders.

Q. Is that view pretty generally entertained by farmers?—A. I think so. There is a feeling that there should be some State legislation especially in the matter of passenger travel. That is pretty general over the State, I think, but nothing has been done for many years. I think the general feeling is that the National Government should control the transportation of commodities.

Q. (By Mr. CLARKE.) Is agriculture in Ohio variegated or does it run to specialties?—A. Both. We have specialists and we have the general agriculturists. In Ohio it is generally mixed husbandry.

Q. Is it your opinion that it is generally more profitable in the long run?—A. I think it is the safer for the average man; the specialist would better go into special lines. By far the larger number of people engaged in agriculture, I think, would better be in general agriculture—mixed husbandry.

Q. Are as many sheep kept in Ohio as there were 15 or 20 years ago?—A. No.

Q. What is the reason for that?—A. Because of the depressed condition of the industry. The industry is very much improving now, but they have not had time yet to increase their flocks to the numbers that they contained 10 years ago. I believe that is the time you mentioned.

Q. The industry was affected by tariff legislation, was it not?—A. Yes.

Q. Is there any reason in the high cost of lands or otherwise why Ohio may not have as many sheep as it ever had?—A. With present conditions I know of no good reason why Ohio may not have as many sheep as it formerly had. The matter of making that an independent industry is affected by the high price of lands, but I think it is true that all farmers can keep a reasonable number of sheep better than not to keep them, under present conditions.

(Testimony closed.)

WASHINGTON, D. C., June 7, 1900.

TESTIMONY OF MR. A. J. WEDDERBURN,

Corresponding Secretary, National Pure Food and Drug Congress, and Master State Grange of Virginia.

The Industrial Commission met at 2.35 p. m., Mr. Phillips presiding. At that time Mr. A. J. Wedderburn was introduced as a witness, and, being first duly sworn, testified as follows:

The WITNESS. My name is Alexander J. Wedderburn. I am corresponding secretary of the National Pure Food and Drug Congress and also master of the State Grange of Virginia. I reside at Dunn Loring Post-Office, Va.

Q. (By Mr. A. L. HARRIS.) How long have you been master of the State Grange of Virginia?—A. Since 1894.

Q. How long have you been secretary of the Pure Food Association?—A. Since its organization in March, 1898.

Q. What is your occupation?—A. I am a publisher and farmer; publisher of the agricultural paper *National Farm and Fireside* at Washington and a farmer in Virginia.

Q. How long have you been engaged in the business of farming?—A. Well, off and on for about 25 years, and maybe a little longer than that—about 26 years. I was identified with the Grange before I was identified with agriculture, although I was raised on a farm from the time I was about 12 until I was about 16 or 18.

Q. Have you at any time been employed by the Secretary of Agriculture or the Agricultural Department to do any special work?—A. I have been employed under Secretaries Coleman, Rusk, Morton, and Wilson as special agent of the Department of Agriculture to investigate the extent and character of food adulteration and made reports to all of them.

Q. How long were you engaged in that work?—A. I think I made 5 different reports.

Q. On what subjects?—A. On the subject of extent and character of food adulteration.

Q. In general, or did you ever make a special report on any particular subject?—A. I made 2 reports on special subjects while engaged on the other work. One was on the adulteration of flour, during the present Administration, and the other was on the adulteration of butter and butter nostrums, which was pub-

lished by Professor Wiley, with considerable addition, as Farmers' Bulletin No. 12, of the Department of Agriculture, under the previous Administration.

Q. Was your report on the adulteration of flour used as a basis for any legislation?—A. Well, it was called for and published by order of the Ways and Means Committee, and the legislation that followed was the bill compelling the proper branding of adulterated flour and the taxing of adulterated flour—I mean the flour bill gotten through by Mr. Gallagher and his associates.

Q. Do you remember the number of that bulletin?—A. That was not published as a bulletin; it was published by order of the Ways and Means Committee of the House of Representatives. They sent for it before it was published by the Department, and published it.

Q. In what year?—A. I think 3 or 4 years ago when that bill was passed—I do not exact'y recollect. I do not think I have had but 2 copies of it, and I do not recollect now about it especially.

Q. We would like to have sufficient information, so we can get hold of it.—A. There would be no trouble in that. It was published at the time the law was enacted, or just prior to the law.

Q. In the Fifty-fourth Congress?—A. The early part of the Fifty-fifth Congress.

Q. You may state, if you will, what you know about the wages in your section of the State.—A. Well, we pay there 50 cents and board for agricultural farm labor and 75 cents without board. Occasionally higher prices are paid. Of course, in harvest time it runs from \$1.50 to \$3 a day; but I am speaking of the average wages.

Q. Paid in cash?—A. Yes. Very rarely, I think, orders are given now. They used to be; but everything is cash now.

Q. Have you employment by the month?—A. Yes. By the month wages run about \$12 with board, or \$15 or \$16; but it is generally by the day and paid weekly.

Q. Is the laborer frequently a married man?—A. Often.

Q. Does the landlord furnish the tenement house?—A. Yes, where he employs by the month or year. In my home neighborhood most of the colored people have a few acres of land and have their own house.

Q. You are speaking of colored labor; you have no white labor?—A. Very little. Sometimes we have what you might call skilled labor; not really skilled labor, but a man who does some work around the farm, such as digging ditches and wells and pruning fruit trees and things of that kind. He would get a dollar a day.

Q. Is that colored labor satisfactory to the employer?—A. Generally speaking, yes. I do not believe our people would be willing to exchange him for any other kind. We are used to him and know what he is. We know he is lazy and good for nothing, but he gets there after awhile, and we do not have to pay him very high wages.

Q. Do you find him trusty?—A. He will steal chickens and will pick up anything that is lying around loose. As one of them told me a few days ago, "Don't leave your tools around; they will take them just naturally;" but he is the best laborer we can get.

Q. Do any of these colored people farm on the shares?—A. Not in our section. In southern Virginia I think there are quite a number who farm on shares, where they are furnished house rent and sometimes provisions.

Q. As master of the State Grange you have been over the State?—A. Pretty well.

Q. And are conversant with agricultural conditions?—A. Yes; not very recently, but a few years ago I was very familiar with it.

Q. You may state if there are any general terms upon which crop sharing is done. Do they share the crop or pay money rent or how is it done?—A. Not a money rent as a rule. It depends on what the proprietor and landlord furnishes. In some places, as I said, he furnishes the land; in others, the land and team; again he advances provisions for the man and his family.

Q. Suppose the farmer only furnishes the land, and the tenant furnishes everything else, what are the terms?—A. About one-fourth. I am speaking now of the tobacco section.

Q. State what crops are raised in this section.—A. Tobacco crop. I lived there for a good many years; what is called "South Side Virginia," in counties south of the James and east of Petersburg.

Q. You may state what share the tenant gets if the landlord furnishes everything except the labor.—A. He then gets about one-third; but rather the general plan was to sell the crop, take out the advance, and then the landlord would get his fourth for the land and the balance would go to the tenant.

Q. Would the landlord furnish the living?—A. He would advance it and charge him for it.

Q. Take a lien on the crop?—A. No; I think the only lien laws we have in Vir-

recommended, that the Interstate Commerce Commission's powers should be increased and enlarged and that they have better facilities for enforcing their orders.

Q. Is that view pretty generally entertained by farmers?—A. I think so. There is a feeling that there should be some State legislation especially in the matter of passenger travel. That is pretty general over the State, I think, but nothing has been done for many years. I think the general feeling is that the National Government should control the transportation of commodities.

Q. (By Mr. CLARKE.) Is agriculture in Ohio variegated or does it run to specialties?—A. Both. We have specialists and we have the general agriculturists. In Ohio it is generally mixed husbandry.

Q. Is it your opinion that it is generally more profitable in the long run?—A. I think it is the safer for the average man; the specialist would better go into special lines. By far the larger number of people engaged in agriculture, I think, would better be in general agriculture—mixed husbandry.

Q. Are as many sheep kept in Ohio as there were 15 or 20 years ago?—A. No.

Q. What is the reason for that?—A. Because of the depressed condition of the industry. The industry is very much improving now, but they have not had time yet to increase their flocks to the numbers that they contained 10 years ago. I believe that is the time you mentioned.

Q. The industry was affected by tariff legislation, was it not?—A. Yes.

Q. Is there any reason in the high cost of lands or otherwise why Ohio may not have as many sheep as it ever had?—A. With present conditions I know of no good reason why Ohio may not have as many sheep as it formerly had. The matter of making that an independent industry is affected by the high price of lands, but I think it is true that all farmers can keep a reasonable number of sheep better than not to keep them, under present conditions.

WASHINGTON, D. C., June 7, 1900.

TESTIMONY OF MR. A. J. WEDDERBURN,

Corresponding Secretary, National Pure Food and Drug Congress, and Master State Grange of Virginia.

The Industrial Commission met at 2.35 p. m., Mr. Phillips presiding. At that time Mr. A. J. Wedderburn was introduced as a witness, and, being first duly sworn, testified as follows:

The WITNESS. My name is Alexander J. Wedderburn. I am corresponding secretary of the National Pure Food and Drug Congress and also master of the State Grange of Virginia. I reside at Dunn Loring Post-Office, Va.

Q. (By Mr. A. L. HARRIS.) How long have you been master of the State Grange of Virginia?—A. Since 1894.

Q. How long have you been secretary of the Pure Food Association?—A. Since its organization in March, 1898.

Q. What is your occupation?—A. I am a publisher and farmer; publisher of the agricultural paper *National Farm and Fireside* at Washington and a farmer in Virginia.

Q. How long have you been engaged in the business of farming?—A. Well, off and on for about 25 years, and maybe a little longer than that—about 26 years. I was identified with the Grange before I was identified with agriculture, although I was raised on a farm from the time I was about 12 until I was about 16 or 18.

Q. Have you at any time been employed by the Secretary of Agriculture or the Agricultural Department to do any special work?—A. I have been employed under Secretaries Coleman, Rusk, Morton, and Wilson as special agent of the Department of Agriculture to investigate the extent and character of food adulteration and made reports to all of them.

Q. How long were you engaged in that work?—A. I think I made 5 different reports.

Q. On what subjects?—A. On the subject of extent and character of food adulteration.

Q. In general, or did you ever make a special report on any particular subject?—A. I made 2 reports on special subjects while engaged on the other work. One was on the adulteration of flour, during the present Administration, and the other was on the adulteration of butter and butter nostrums, which was pub-

Q. That is the burning question?—A. I think so. Of course we have the question of suffrage, but I do not think they would have called the convention for the suffrage question alone, because a great many white people, if an educational qualification is made, would lose their vote; it cuts both ways. But the strongest white district went strongest against the constitutional convention, and the strongest black district went the strongest for it.

Q. You do not think the color line has much to do with it?—A. Of course it had some, but not as much as the other.

Q. Does the value of your agricultural property keep up?—A. No, except under exceptional circumstances. For example, counties adjoining Washington have increased in value; valley counties and some sections where there have been a great many mining industries established, and a great many people have come in, have increased in value; but, as a rule, take the State over outside of these special localities, property has decreased in value.

Q. What is the cause of that decline in value?—A. There are two troubles. One is the decline in the profits of farming, the decline in prices of agricultural products; the other is that we have not enough population for our territory, and that population to a certain extent is kept away, as the white laborer does not come because we have the negro labor, and they do not mix very well.

Q. Have you any abandoned land?—A. No; I think not. There is some that has been sold to the State for taxes, but not what you would call abandoned land. There may be some in certain sections that I know nothing about, but the farms are generally occupied, and the houses are generally occupied by somebody. You rarely see an abandoned house.

Q. Is there any decline in the productivity of your soil?—A. No; I rather think where the soil has been properly cultivated and fertilized the yield would be larger than it has been. I know it is absolutely possible, from my own experience, to very largely increase the yield of farm products by proper cultivation and fertilization.

Q. What kind of fertilizer do you use?—A. I used to be the representative of the State Grange for several years as agent, and manufactured fertilizers largely; and for my own purpose I use potash and phosphoric acid, trying to supply the ammonia from my barnyard manure.

Q. (By Mr. FARQUHAR.) Is it a fact that the impoverishment came a great deal through the slave labor in the old days?—A. It came from most outrageous cultivation. The fact is, they would get an immense number of slaves—and up to a few years before the war, when Peruvian guano was introduced, there was no kind of fertilizer, and they knew nothing about it—and go in and cut out the trees and dig out the roots and put in tobacco; put all the stable manure that they had on that ground and plant it in tobacco until it ceased to grow tobacco, and then plant it in wheat for 2 or 3 years, and then vary with corn and oats, and oats and corn, and corn and oats, until they killed the land; and that is the cause of the impoverishment of Virginia, as well as I can understand. I saw that system in southern Virginia when I was a boy, and I am pretty well satisfied it is the system they have tried everywhere.

Q. Lack of diversity of crops and continuous cropping year by year?—A. Yes.

Q. Taking all from the earth they possibly could?—A. And putting nothing back. Take this land I have; within 12 miles of where we are sitting I own a little property: I went there and found old-field pines, cut them down, got the stumps out, and fertilized it with potash and South Carolina phosphate—about three-fourths phosphate and one-fourth potash; put it on pretty liberally and put on the leaves and muck I got on the land, and I followed that up, and can produce as good a crop on that little piece of land as anybody can. Other men who raise wheat in the county have done the same thing, and we produce as high as 30 and 35 bushels to the acre. A better system than mine but a little longer one, would be to sow the land in black-eyed peas, or rye, or any other one of the—

Q. (Interrupting.) The Vetches tribe?—A. The Vetches tribe, and then turn under the soil. You might call that simply using the green crops for improving the value of the land, and it will do it much more rapidly than anything else. I have a neighbor who bought a field of 30 acres and built a house 4 years ago, adjoining my land. It would not produce anything hardly. I do not think it would produce 3 barrels of corn per acre. He began by fertilizing it; set it out in fruit trees, and then planted between these trees this crimson clover and peas, and his ground is almost as dark as this table to-day, and his trees have grown into a magnificent orchard in this short space of time. Nobody wants a better or nicer farm. He is an employee of the Government and lives out there. His name is Snyder.

Q. (By Mr. A. L. HARRIS.) How much is your farm land worth on the aver-

age?—A. I paid \$40 an acre for mine in the woods, but we are right at the station and have a railroad running right through my land—most of it station land. I consider it worth more than that, but the land between here and Leesburg generally ranges from \$100 to \$125 an acre. It is a short distance and a great many go out there and are building up a neighborhood and community. It is just a little beyond Falls Church. I am only about 3 miles from there.

Q. Have you any knowledge of the value of the lands in the tobacco portion of the State?—A. I bought land there some years ago at anywhere from \$3 to \$10 an acre, and I expect the same could be done to-day. Thousands of acres were for sale there a few years ago, when I went down there often, at less than the cost of the improvements.

Q. Improved land?—A. Yes; and the improvements were much more valuable than the land cost if you had to put them up.

Q. Do you know how many pounds of tobacco that land would produce?—A. That would depend entirely on the cultivation and the amount of fertilizer put on it. Some sections of that country—take it around Danville—I suppose lands have gone up materially; they have gone into the bright or yellow tobacco culture. The section of the State I was more familiar with was Lunenburg and Charlotte counties. Near Petersburg and Dinwiddie they raised the shipping tobacco—and good tobacco, too—but the yield, I think, was—probably a fair average on a good piece of land would be a quarter of a pound to the hill—for the heavy shipping tobacco, you know. I guess you had better say about 5 plants to the pound. Of course the negroes who did not cultivate well or the slovenly farmers did not get anything like that, but I am speaking of a good farm, fair land, well fertilized and properly cultivated.

Q. Is the state of agriculture improving down there?—A. I could not answer. I have not been there for some little time. In our northern section I would say it is, decidedly.

Q. What is the value of farm lands in other portions of the State?—A. The valley lands have always been high. They run, according to the distance from the railroad, from \$25 to \$100 an acre, from one end of the valley to the other. Loudoun County land runs from \$40 to \$50 and maybe \$60 around villages and towns. Lands in Prince William County, within 30 miles of Washington, have sold at auction for less than \$1 an acre in the last few years.

Q. (By Mr. FARQUHAR.) What is the reason of the low price?—A. Take for example Bristow Station and Noaksville Station, a few years ago—12 or 15, maybe—the land was valueless. Northern settlers came in there and went to improving their land and raising grass, and now instead of buying hundreds of tons of hay as they did then, they ship hundreds of tons. The land has increased largely in value. It is all susceptible of improvement. Those cheap lands lie 5 or 6 miles from the depot—men came in there with sawmills and bought it, giving \$2 and \$3 an acre, cut off the heavy timber, and sold the land for anything they could get, as I say, for \$1 an acre, and glad to get rid of it; did not want to cultivate it.

Q. (By Mr. A. L. HARRIS.) Could dairies be established?—A. It would make fine dairy land.

Q. Would dairying be profitable?—A. From here to Leesburg, from here up to Manassas, I think, thousands of gallons of milk are shipped into the city here every day. There is no creamery business done. One or two started in Loudoun County, but I do not think they proved successful.

Q. Is all the land occupied that could be used profitably for dairying?—A. Oh, no.

Q. Is there not a future, then?—A. An immense future, if we could just get the people to come there and settle; if we could only get them to understand that we have the lands, right under the shadow of the Capitol, almost as cheap as they could get them by going thousands of miles away.

Q. Where did the farmers come from who settled in the neighborhood of Bristow Station?—A. I do not know. I know that there are some Iowa farmers and some from New York. They were in the grange. And I know there were one or two Ohio farmers. Mr. Dodge was from Ohio.

Q. Has the investment been a profitable one to them?—A. I would not like to answer that, because I do not know; I hope so. Mr. Dodge is a practical and a prosperous farmer and seems to be well to do. Mr. Dodge was at Manassas, Mr. Mellon was at Nokesville, and Mr. Smith was there. But these two men—I recall their names and recollect their farms—have fine farms.

Q. Are they pretty largely engaged in stock raising?—A. I don't think they raise stock very much; raise grass more than anything else. They sell grass. I don't recollect positively what they do, but I know they make hay around Nokesville, and I think Mellon made a great deal of it. Mr. Dodge has a fine place at Manassas.

Q. Have you any organizations of farmers in Virginia?—A. Practically none. We had the Grange at one time very largely organized, but it got into politics and broke up, and then we tried to keep it up for a number of years, but it is practically out of existence.

Q. Did you have the Farmers' Alliance at any time?—A. Yes; that went the same road, only a little quicker.

Q. Do you have any farmers' clubs?—A. Occasionally, here and there. The Horticultural Society is, I think, the only thing that is practically keeping up an existence in the State now. We have several very fine farmers' clubs; one in Fairfax County near the Mount Vernon place, called the Woodlawn Club, principally people who emigrated from New Jersey, Quakers; fine, elegant character of people, who have been there ever since before the war; bought some of the original Mount Vernon estate; thrifty, intelligent, industrious, and successful farmers. I know little about the neighborhood, but I know something of the people, and know them to be just what I have described them to be.

Q. You think there is a general improvement among the farmers?—A. Yes; of course there is an improvement, and yet there has been a change of farms, and a change of men. Property has been improved in certain sections. I am speaking principally of my own section. Of course we have the advantage of Washington; but as a rule I do not think the farmers have made much money, and they have had to be very economical and forced not to buy what they would like, because they do not have the means to pay for it.

Q. Is the cost of production too high for profit?—A. Absolutely; not only the cost of production, but the cost of everything that is used in the production. The farmer has had to pay a tremendous high price for everything. He has had to pay the price of the product manufactured in this country and protected by what I consider an unjust Federal law; he has been made to pay more than the real value of the product simply because the law enabled the other man to charge it; and he has had to sell in a market which gave the other man the privilege of getting his products, especially his staple products, at a price that the world gives—that was fixed in the world's markets.

Q. Now, the products that he bought, that have been high, what did they consist of?—A. Take barbed wire, for example; take every farm implement, for example; take all that he wears and everything he uses on his farm, and building material. Take glass. I have bought 50 or 60 windows for my house this year. If I had bought them 2 years ago they would have cost me, I think, at least one-third less. I know that the price has increased at least 30 per cent. On the barbed wire that I bought 2 years ago and some this year—not only barbed, but plain wire, wire fencing—the price had been advanced from \$2 to \$1. It has fallen to \$3 now, but, alas, I have bought mine. There has been an advance of 75 to 80 per cent in the last 2 years on the price of plows, and on the price of everything—every manufactured product that comes under the protective-tariff laws of the United States, so far as I am able to find out.

Q. What is the price of your fencing wire used 1 year ago?—A. A year ago the price had gotten up, but before they formed this combination called the Steel Trust I purchased wire at about \$2 a hundred. The last I bought cost me \$3.50, and it then went up to \$4. I understand it is now down to \$3. My merchant told me that a day or two ago.

Q. There is no additional tariff on wire.—A. Probably not. That is a combination. But there is upon steel and its products, is there not?

Q. (By Mr. FARQUHAR.) Is wire a patented article?—A. A great many patents.

Q. On steel wire?—A. I say there are a great many different kinds.

Q. The barbed wire usually that the farmers desire is a patented article, is it not?—A. I do not know. I presume so. But the same product that sold for \$2 was raised afterwards to \$1. I think that was due to the combination principally, and it is now, as I said, selling for \$3 per 100 pounds.

Q. (By Mr. A. L. HARRIS.) Will they be able to maintain those prices?—A. I hope not. I do not want them to lose anything, but I hope they will not keep them up, because we can split rails and put them on the place at a less rate than we can buy at \$4 a hundred pounds, I think.

Q. (By Mr. FARQUHAR.) You speak of articles that enter into the family being raised in price to the consumer by an unjust tariff. Is sugar raised? Is your clothing raised? Boots and shoes raised?—A. On boots and shoes I do not think there is any tariff. The sugar combination is all in the hands of one party, as I understand it, and they raise and lower it to suit themselves.

Q. Do you not get cheaper sugar now than you ever did?—A. Oh, no. I do not see that it is any cheaper. I am not a chemist and do not know whether it is any purer; and it is not any cheaper. I think it is a little higher than it has been. It certainly raised for a time about three-quarters of a cent retail.

Q. (By Mr. CLARKE.) I will ask you with what period you are making your comparison on sugar?—A. Probably 3 or 4 years ago it was down and retailed at 5 cents, and got up to 6 and 6½ at one time, and now I think it is probably 5½ or 6 cents, according to the quantity in which you buy it.

Q. You know under the tariff of 1890, commonly called the McKinley tariff, sugar came in free of duty?—A. Yes.

Q. And then there was a duty placed on it by the next tariff, commonly called the Wilson tariff, and that duty or some similar duty has been continued since?—A. Yes.

Q. Are you making your comparison of the present price with the price under the tariff of 1890 or that of 1894?—A. The fact of the business is I am getting a little beyond my depth, and I do not like to talk about these things; but my general impression is I paid at one time as low as 5 cents for my sugar, and it costs me 6 about now.

Q. Have you made any investigation in Virginia as to the feasibility of growing the sugar beet there and making your own sugar?—A. There was some made around Winchester, and the analysis of the beets as sent to the Department, I understand, was very satisfactory. There was some talk at Fredericksburg of establishing a beet factory, but I do not know what it has come to. I have raised some beets from the seed sent me by Dr. Wiley. They were very fine and nice. I sent them samples, but not being fixed to go into that business I never asked him what the result of the analysis was.

Q. There is no sugar-beet industry in Virginia now that you know of?—A. No. Dr. Wiley told me at one time that he rather thought that, except around Winchester and around that belt of the State, Virginia was rather out of the line.

Q. Is there much wheat grown in Virginia?—A. I do not know. There is a good deal in the valley of Virginia and through the Piedmont section and some little in southern Virginia.

Q. Any in Alexandria and Loudoun counties?—A. In Loudoun, a little. Corn is the principal Loudoun product, and in Alexandria I do not know of any wheat. A little wheat is raised in Fairfax County. Wheat does not pay us at all.

Q. Are you acquainted in western Maryland?—A. Yes. I understand that in this portion of Maryland adjacent to the District, Washington and Montgomery, they raise very fine wheat crops.

Q. Is there not a great similarity between your soil and theirs and your climate and theirs?—A. Very much the same thing. I stated that we had raised to my knowledge as high as 35 bushels per acre of wheat in Fairfax County, within a few miles of Georgetown.

Q. Is a great deal of your farming carried on by machinery?—A. No; our farms are not large. We use the mower and reaper and thrashing machine and plow. We have the binder in the larger wheat-growing sections, where a man raises 300 or 400 bushels. That is about the largest amount with us.

Q. Cultivators and seeders are used, I suppose?—A. Yes; we use the grain drill. Of course we buy for our gardens and farms the latest improved plows and cultivators we can get.

Q. Hoes, spades, and shovels are in universal use?—A. Yes; those are old means. I supposed you referred to those used on bonanza farms, etc. We have all those, of course. Our people try to use the very best they can get.

Q. Do you know how the prices of those implements and all ordinary implements like plows, harrows, etc., compare with those of, say, 25 years ago?—A. No; I do not recollect. I know that the plows and most of the steel implements are higher than they were 3 to 6 years ago.

Q. Do you know whether the prices 3 or 4 years ago were remunerative or not?—A. To the manufacturer? I do not know.

Q. Do you know how these prices compare with prices of similar articles in England?—A. No. I see from Congressional reports that some years ago, during the Fifty-second Congress probably, some machines selling in this country at certain prices were sold in Europe and Canada at considerably less prices, but I do not know that only from the Congressional report.

Q. You know that it is something of a practice with all manufacturing countries to make a lower price in foreign markets than they do in the domestic market for a while, in order to build up a trade?—A. I did not know that. I would not blame them for doing it; but the only thing I know about this whole matter is that I would like to see the farmer—I am not trying to attack the protection of the manufacturer or his products provided the farmer is given an equal protection that will enable him to buy that product. What I do not like and object to is the fact of protecting the manufacturer and making the farmer pay the bill and letting him scuffle for his price on his product.

Q. What farm product is it which does not enjoy a fairly equal protection with

the manufactured products?—A. The fact of the business is I do not believe there is any farm product except wool that has any protection at all, that I can recollect.

Q. Do you not know there is a protection on tobacco?—A. What is the good of it? Do we not export thousands and thousands of pounds where we import one?

Q. Tobacco?—A. Certainly.

Q. Have you examined the subject so that you have definite knowledge?—A. I know that for some years we exported thousands of pounds of tobacco where we imported one—I will not say thousands, but certainly many hundreds where we imported one. We import from Cuba and Manila, but—

Q. (Interrupting.) Take farm gardening now. You know that when the Wilson bill was pending in Congress the Bermuda farmers came before the Committee on Ways and Means and asked to have the duty taken off from vegetables, such as they exported to this country, and Mr. Bryan, who was a member of the committee, asked who paid the duty on these vegetables, the American consumer or the Bermuda producer, and they replied that the producer paid the duty—the exporter. Now, do you not know that these duties exist on all vegetables, such as the people of this country import from any other country?—A. I am perfectly familiar with the fact that in the tariff bill there are protective duties on products from abroad, just as they levied in the McKinley bill, a tariff on eggs. I do not know whether that was put back under the Dingley bill. They had a tariff on wheat, on tobacco, not on cotton, and yet cotton is brought in from Egypt in rather large quantities, and sufficiently large quantities to materially reduce the price of the sea-island cotton, which is the particular staple of cotton that comes from Egypt and the steppes of Russia. Now, I know that this Government has these protective tariffs; but when you come down to vegetables, practically they amount to nothing, because transportation in localities might have a great deal to do with that; but when you take the great staples of wheat and cotton and tobacco and corn, the great staples that we ship from this country abroad and which form a large proportion of our exports and bring our money here, no matter what protection is put in a tariff bill, no matter whether great or small, it amounts to nothing as a business proposition, if it is put in simply for the purpose of deluding the man who raises it. It is wrong. As a protection you might as well put your protective tariff on wheat at \$5 a bushel, and it would not amount to any more than 10 cents or 1 cent or no tariff at all. We ship these products abroad. The price is fixed at the central market of the world, in Liverpool, and we pay the same price here that is paid in the Liverpool market, less the cost of transportation to Liverpool.

Q. Is Virginia exporting any wheat?—A. Virginia is not exporting any wheat. Virginia is buying wheat. She exports tobacco.

Q. Do you know any Southern State that is exporting either wheat or corn?—A. No: they are all importers of wheat and corn.

Q. Do you not know that Bermuda vegetables and vegetables and fruits from the West Indies are delivered in New York at a lower cost of transportation than the same articles cost from the Southern States?—A. I do not know, but of course the facilities for transporting by water and rail are so different that I should presume that would be a fact.

Q. You are aware of the fact, are you not, that large quantities of garden truck and fruits, vegetables generally, are sent from the Southern States to New York and New England markets?—A. I am; and on the floor of the National Grange I advocated the proposition to give an export bounty on agricultural staple products, which I would like to emphasize here, believing it to be to the best interest of this country that such a bounty should be given. I stated on the floor of the National Grange that the New England farmer, the New York farmer, and New Jersey farmer, who were truck farmers or producers of nonstaple products—when we advanced the price of cotton and tobacco for the South and corn and wheat for the West and sent it abroad—when we made it profitable to raise the staples, we would stop the Southern competition with the Eastern trucker; but that as long as a governmental system existed in this country which aided in depressing the price of agricultural staple products, it would drive the farmer in Virginia from his legitimate work of raising tobacco, the farmer in Georgia from his legitimate work of raising cotton, and the Iowa man from raising his wheat and corn, and drive him into making butter, and in making the other fellow go into raising watermelons, compelling them to compete in their own home, in their home market; and therefore it is for the advantage of the New England farmer and the farmer around the manufactories who want to produce farm products and truck that they should do everything they could to increase the price of staple agricultural products. I believe it as firmly to day as I did in 1896, when I made that statement on the floor of the National Grange.

Q. Do you favor a duty on long-staple cotton—Egyptian cotton?—A. I would

favor a duty on long-staple cotton, if we are going to have a duty on anything. I believe if you are going to protect one class of people you should protect all. The American farmer has just as much right to be protected as the American manufacturer.

Q. Do you think the people of the South generally would favor a duty on sea island cotton—on long-staple cotton?—A. I am not in a position to answer that question. I think they ought to. They have just as much right to favor it. I don't believe they would favor it provided other things were free; but I think the Senator from South Carolina (Senator McLaurin) occupies the position I would occupy, that, as long as other things are taxed, and these men are taxed for everything they use, they have as much right to be protected as the other men.

Q. Are you sure that they are taxed on everything that they use?—A. I believe that everything that is protected has a fictitious value put upon it—that there is no person in the world that pays that tax except the man who pays for it last and consumes it—that is, if he pays for it. If it is given to him he don't pay the tax; but the man who pays for it when it comes to consumption is the man who pays the tax.

Q. If you were satisfied that the prices were no higher here than in England for the same article, where they have a different system of taxation, would you think that the consumer pays the duty?—A. You mean on American products?

Q. Yes.—A. If, for example, it was made by a manufacturer in this country and it was sold in England at the same price as sold in this country?

Q. Yes.—A. Why the difference in freight from here to England would settle that—give the Englishman the advantage.

Q. (By Mr. FARQUHAR.) Do you believe in an export bounty for anything else in the United States outside of agriculture?—A. I believe that the best system that this Government could adopt would be to pay a bounty upon everything that we ship out of the country, because by shipping a surplus of products away from the United States we bring back here money instead of goods. That is the difference between Mr. Lubin's position and mine. I have always advocated that this thing be extended to manufactures so as to build up American shipping—American marine.

Q. (By Mr. CLARKE.) To whom would you have the export bounty paid?—A. Well, it would be paid, of course, to the shipper; but I could furnish you literature of the very highest character, most of it public documents, which would demonstrate that the farmer would be bound to get his portion of it. There was a statement by the secretary of the Chicago Corn Exchange to the effect that the competition was so great among the purchasers when bidding on the stock exchange—they have a dial up there [indicating] that fluctuates back and forth, one-eighth, one-sixteenth of a cent; and a great many large transactions are made on such a close margin that the man who produces a product would be bound to get a large proportion of the proposed bounty of either wheat, cotton, or anything that was sold upon these exchanges. I believe Mr. Lubin clearly demonstrated that fact.

Q. I believe I understand your contention is that these staple farm products sent abroad from this country compete in the foreign market with similar products from other countries?—A. Yes.

Q. Suppose a bounty were paid on the exportation of these products, would not the shipper be thereby enabled to sell those products in the foreign market at a lower price than the normal price made by competition in other countries by goods from other countries?—A. Well, would it be likely that he would do it? For example, do you suppose that he would want to sell his products at any less price than the market price? Don't you suppose he would want to get the very highest market price? Now, you understand here is a relative position. [Indicating.] There is Liverpool. [Indicating.] Now, we take the wheat market for example. We ship from here [indicating]; the Argentine people ship from there, and North Africa comes in here; the Russian people come in here, and the Danubian here. There are five points which fill up this great bin with wheat until it overflows. The surplus, no matter where it comes from, India, Africa, that surplus fixes the price; and England tries to increase that surplus to reduce the price, and she pays for it in silver to still further beat down the price. The whole price is fixed in the central world's market in Liverpool, fixed by supply and demand; no question about that; and the price in the city of Washington, or in the city of Milwaukee, or in San Francisco is identical at the same time and is the same price as it is in Liverpool, less the cost of transportation to Liverpool. The world's central market fixes the price to the farmer in Washington, Oregon, California, or Virginia. He has to take the Liverpool price for his product, in competition with this cheap labor in India, in South Africa, and in North Africa, and in Russia—labor that runs from 6 cents a day to 20 cents a day. Now, you gentlemen want to protect American labor and American industries. What I am asking you is to

try and find some means to protect the greatest industry in this country, the American farmer; put him on a plane with those other people. I am talking about the producer of staple agricultural products, or the man who exports. He is the man who undoubtedly pays the entire tax in this country. He don't take it out of his pocket and pay it in a direct way, but he has to pay for the cost of everything that he uses and, being a producer of wealth, the producer of the surplus that brings money back in this country, he pays the entire tax.

Q. Does he become impoverished by his business or does he gain something?—A. Well, a few years ago, it seems as though he pretty nearly ran out. I think there are a great many changes in farms: a great many who have owned farms have become tenant farmers. I think probably this census will show more tenant farmers than we ever had in this country.

Q. Do you know any other country in the world where so many farmers own their farms free of indebtedness as in this country?—A. That possibly may be true, but I would like to just call your attention to one or two figures, if I can find them here. I hope it won't be, but I am very much afraid that this census will show a worse showing than this. They are here in Mr. Hatch's report. Now, you speak about this farming business. I have got the report of Mr. Hatch on March 2, 1895. Of course these figures, maybe, have very materially altered, but it showed that we had farms—we find the number of farms in the United States to be in 1890, 4,564,641, while in 1880 there were 4,008,907, an increase during the decade of 555,734. That is the increase in the number of farms. The percentage of increase in the decade was 16.25 per cent. Now, the number of farms in the manufacturing States of New York, Pennsylvania, New England, show a decrease of 5.40 per cent; an acreage of 5,242,115 acres, or a decrease of 7.71 per cent. Now, the point I really want to bring out—I will just show you this—here is the production: The actual increase per acre was one-tenth of 1 per cent between 1894 and 1880, but the loss in money between the same years was \$248,299,825.

Q. The loss in money?—A. Actual money loss. There was an increase in bushels, an increase in yield per acre, but a loss in money value between those years, 1894 and 1880, of \$248,299,825. The farmers' wealth of the United States in 1860 was nearly one-half of the entire wealth of this country. In 1890 it had decreased to one-fourth, held the position of one-fourth; and yet all this vast expenditure of money on farms in the United States, and the vast increase of acreage, the vast increase of capital and production on our farms, and still the census figures show that the farmer had fallen from half nearly to one-quarter owner. I think that answers your question about the prosperity of the farmer to that extent.

Q. Do you know that the increase in the average wealth of farmers in 30 years was practically from two hundred to three thousand dollars, or about that proportion?—A. No. I never saw those figures, and do not know where they came from, but I can not understand how that could be, when the farmer, as a class, had descended from the position of 50 per cent to a position of less than 25.

Q. On what are your figures based, the value of the farm products for the particular year you named or on the value of the total property that the farmers had?—A. My last figures were based on the total property that the farmers had. These others were taken from Colonel Hatch's report. Mine were based on the report of 1890.

Q. Who is Colonel Hatch and what is his report?—A. Col. William H. Hatch was chairman of the House Committee on Agriculture, from Missouri.

Q. In what?—A. Of the Fifty-third Congress; March 2, 1895. This is Report No. 1399.

Q. Why don't you take the reports of the Department of Agriculture?—A. I have taken them. I find it right in here in the statement I made. I think I used them to show the amount of production in Argentina and their competition with us here in this country.

Q. Well, now, has not that competition of Argentina and Australia and of Russia with this country enormously increased from 1880 to 1894, the periods that you are comparing?—Undoubtedly. It must have done it; yes. I do not question that. I think that is true.

Q. That would account then, would it not, for the decline in prices of such farm products as are exported?—A. Undoubtedly. That is just what I tried to make plain, as stated—that it is with this world's market and with the home market that the farmer is compelled to compete.

Q. Well, you think that the farmer loses money on everything that he exports?—A. Oh, no; I did not say that.

Q. If the farmer is growing poorer it must be so, must it not?—A. I think this. That the farmer is brought into unjust competition at home and abroad; abroad by being compelled to compete, when he pays from 50 cents to \$1 a day for labor, as against men who are paying from 6 to 20 cents for labor in the open markets of

the world; that he must take the price set by these men, with this cheap labor and cheap lands, and our American agricultural implements, as proven by Mr. Lubin and statistics of consular reports too; that he has to compete with that class of people, land, and labor, and he has at home to buy and pay on a protective basis for everything he uses to produce that.

Q. Does he have to pay any more for these things than his foreign competitors pay?—A. As I stated a little while ago, I understood in some cases that he did; but even if he did not have to do that, if the foreign competitor uses the same binder made by Mr. McCormick in Chicago, who, I see, has shipped 3,000 binders to the steppes of Russia, our farmer has got to compete with that cheap labor and cheap land and Government bounties, in some instances, to get the stuff to the market—as in the Danubian provinces, the railroads carrying practically free, or very much less than any other thing, grain exported from that country, as I understand—our farmers still stand at a disastrous disadvantage.

Q. What proportion of the farmers of this country are engaged in raising articles that are largely exported?—A. I do not know that, but I know that those who are engaged in supplying these exports produce enough not only to supply the home demand, but furnish over two-thirds of the export balances that the United States secures, of the export balances that come into this country.

Q. Is that statement based on the figures of the last year?—A. I think not; probably. I have not seen the last year basis, but prior to that it was certainly two-thirds, prior to a year ago; I have not seen the statistics within the last year or maybe the last 18 months.

Q. (By Mr. FARQUHAR.) Can you state the proportion of agricultural products that are consumed in the United States in comparison with those exported? Is it not generally conceded that between 5 and 10 per cent is exported?—A. Yes; I understand that. We fix our own price for that which we do not ship out—I mean butter, eggs, cabbages, and things of that kind—but not on these other products that we ship abroad, the products that bring money into this country; what was, as Mr. Seymour said 25 years ago, the statesmanship of the plow that enabled the American Government to resume specie payment, the surplus that goes from this country and brings back money instead of product, is furnished, two-thirds of it, by the farmers of the United States, the producers of staple products—wheat, corn, cotton, tobacco, etc.

Q. What does the farmer contribute to the \$53,000,000 the Standard Oil Company brings into America out of American product?—A. Contributes nothing in the world.

Q. So that of the balance of trade, consisting of machinery and manufactures and everything else, amounting to 5, 8, or 10 per cent, the farm exports certainly can not bear the volume that you say?—A. You will find the agricultural products exported from this country amount to even now over 60 per cent of the entire exports. That can be verified without question. I would like to show it to you for 1894 and 1895; it was 74 per cent that year—in 1893 or 1894. Why, the cotton product that we ship abroad amounts to, I would not like to say absolutely, but it is about 40 to 50 per cent of the entire product in value; there is no trouble to get those figures; I supposed they were so well known that I did not even take the trouble to bring them up here.

Q. (By Mr. CLARKE.) And yet you think the farmers are growing poor?—A. Well, I think I said that the statistics of the United States in 1890 showed that they had gone back, that their lands had gone back, the total value of all their products had gone back. They furnished that which brought wealth to this country, but unfortunately through some cause or other did not manage to keep that wealth for themselves.

Q. Have you read Mr. Mulhall's examinations of the results of the census of 1890 in this country?—A. No. I saw them at the time, but I have forgotten. I am not much of a statistician. I have the figures here right before me that in 1893 there was \$831,030,785 of exports from the United States, divided among mining, forestry, manufactures, fisheries, and miscellaneous. The total agriculture amounts to \$615,382,986. That I think you will find runs about 74 per cent, which is my statement. The last 2 years we have exported more merchandise, and the prices of agricultural products have not kept up so well except just during the war.

Q. I saw it stated a few days ago that the wheat crop of Kansas this year will amount to 80,000,000 bushels. I may be mistaken as to the figures. Is it your opinion that the growers of the wheat in Kansas are poorer by reason of it or better off?—A. Why, they certainly are not poorer by reason of it; and even if they get a reasonable fair price and make some money, there is no reason why they should not make more. There is no reason why they should have to pay more for the machinery necessary for the production of that crop and for the goods that

they are compelled to use even as luxuries or necessities, and secure no protection themselves.

Q. Do you know that they do pay more for that machinery or other goods than otherwise?—A. I do not know about Kansas, but I know I have myself, in purchasing products in the last 6, 8, and 12 months; all the prices were higher than they were several years before.

Q. Well, you don't know whether they were fairly remunerative before, do you, during the period of the depression?—A. I don't know. I hope that they were. I do know that during that period of depression the farm was not remunerative.

Q. The prices may have been advanced too much, but perhaps should have been advanced somewhat?—A. That is probable. I do not want to be misunderstood. I am not fighting the prices of others; I am not attacking anything that is legitimate or proper; but I do want to see our own people receive some benefit while others are doing the same thing.

Q. By reason of there being a large manufacturing industry in this country and also mining and transportation, giving employment to 60 per cent of the people, do you not think that the farmer gets an increasingly valuable home market which enables him to dispose of a much larger quantity of products than he otherwise would?—A. The horticulturist, the dairyman, the poultryman, and the vegetable raiser probably do; the man who produces wheat and corn, cotton and tobacco, does not.

Q. Is there not more wheat, corn, and tobacco consumed by reason of this large population?—A. That may be; but it certainly does not alter the proposition, because the prices are fixed at Liverpool. The prices of the export products are fixed abroad; not in this country.

Q. (By Mr. FARQUHAR.) Does America help to fix that price?—A. I do not think that America—

Q. (Interrupting.) Does Argentina help to fix it?—A. In a sense, it does.

Q. Does Russia help to fix it?—A. Undoubtedly; all.

Q. The Liverpool market is the world's price?—A. That is exactly what I said.

Q. And all corn-producing countries are contributors to that price?—A. It is a question of surplus which fixes the price—too much or too little.

Q. Do you think any power in the world, legislative or otherwise, could change that price?—A. No; I do not. The only legislative act which could change it would be to give a bounty on the export product. If Congress gave a bounty on the export product, it would not only put up the price on the product that was exported to, say, 10 cents a bushel, for example, on the 280,000,000—not only be this 10 cents, but it would raise the price in the whole market 10 cents.

Q. And you are also aware that every foreign country receiving these bounty-exported cereals has a right to put a countervailing duty on cereals, just as we do on German sugar to-day, so what difference does it make?—A. They have a right to. England, the market to which it goes, would not avail itself of that right, because it would not cost them one cent more. It don't make it cost them any more, and they want wheat. We are merely trying to protect our own sugar industry when we are trying to prevent Germany from shipping sugar in here; we have specific reasons for it; but England is striving for our wheat. Anyhow, I do not think that would be exactly the same thing.

Q. (By Mr. CLARKE.) You are aware that Germany pays an export bounty on sugar?—A. Yes.

Q. And that German sugar is sold in the English market for less than it is in the German market?—A. I was not aware of that, but I could see very well why it should be.

Q. Well, now, would it not work the same way on wheat?—A. No; we do not send our wheat, or very little of it, to Germany. The price is not fixed in the German market even if we sent it there. You acknowledged that the price was fixed in the Liverpool market.

Q. Would not our export-bounty wheat sell for a lower price there than it sells for here?—A. No; I do not see how it would, except the amount of the bounty. I tried to answer that question some time ago. I am sorry I did not have the ability to do that.

Q. I wanted to see how, in your mind, this wheat differed from sugar?—A. I gave you the reason; the market man in Germany is trying his best to find a market on which to sell his product. He has a tremendous surplus and will sell it at any price; but England is grabbing for the wheat of the world; she can live without sugar, but she can not live without bread.

Q. Is it not a fact there is great competition in the Liverpool wheat market between sellers?—A. I do not think so. Everything that shall be sent there and every extra bushel that goes in of course helps to depress the market; but I am not trying to discuss what is going to happen in Liverpool, whether the price is going to be lower or higher there. I am only contending for higher prices in

the United States. I am contending for the same opportunity for the wheat raiser that the manufacturer of steel is getting.

Q. I want to bring your mind to the question of what will happen there if we paid a bounty on wheat.—A. Do you believe that we will be doing any great harm if we break the prices of wheat for the English people and not hurt ourselves at all; increase our prices and break theirs?

Q. Well, if the price of wheat becomes lower there than it does here, as you think it would, is not that going to enable the industrial population of England to manufacture goods cheaper than they can be manufactured in this country?—A. That is a new way of putting the case to me, but I suppose that could be met, you know, by the gentlemen who managed to keep out those goods by raising their tariff.

Q. They do not have a tariff on those goods in England.—A. I am not bothered about what is going on in England. I am talking about keeping them out here. It does not make any difference what they are selling at in England. We are not interested in that question at all, as I can see. It is the home price that affects us.

Q. Well, if they should be able thereby to manufacture goods in England lower than they can now, so as to compete more vigorously in this market, would you favor, as an offset, an increase in duty on those goods in this country?—A. Practically and thoroughly I do not believe in protective tariff; but if we are going to have a protective tariff for the benefit of manufacturers, I favor a protective tariff, which can only be given by bounty, in favor of agricultural exports.

Q. (By Mr. FARQUHAR.) Do you think the export bounty there would give the American farmer impetus to raise more wheat?—A. It might.

Q. Do you think 100,000,000 bushels of American wheat extra put in Liverpool market would make any difference in the price?—A. Undoubtedly it would.

Q. Possibly what was gained in bounty would be lost in a large part in the general price?—A. It might do that. Mr. Wood Davis, of Wisconsin, states, and he has given the question a good deal of attention—was here in connection with the future business—and he states very positively that the area for the production of wheat in the United States is about covered, and that we can not expect to raise very much larger crops than we have now. I think that is true, too.

Q. You think those statistics are borne out by census statements at all?—A. There has been no opportunity for that since then.

Q. Between 1860, 1870, 1880, and 1890?—A. Then you developed in the great Northwest. It is developed now. Where are you going to get new wheat land? Every year you farm those lands without fertilization, without some means to improve, and rotation of the crops, I think you must depreciate their productive value. I should think so. I may be mistaken.

Q. Can you give the commission an idea how much out of the export bounty the farmer is going to get?—A. It was stated here on the floor of the Senate by several Senators. I think, in their speeches on the subject. There were, I think, five or six very able speeches made in the Senate on the subject.

Q. By farmers, statisticians, or lawyers?—A. They were Senators, Mr. Cannon of Utah, Mr. Tillman of South Carolina, and Mr. McLaurin of South Carolina. Mr. Cannon made a wonderfully strong speech, argumentative speech, on the subject. I do not recollect who the other gentlemen were, but I think there were four speeches made and some 8 or 10 votes cast at the time in favor of the amendment. They, of course, just offered it as an amendment, without any hopes of carrying it through. They got more votes than I thought they were going to get. The estimate made by Mr. Lubin and, as I stated a little while ago, by the secretaries of the exchange in Chicago, and, I believe, pretty much the same thing from the New York Exchange, that the transportation companies, the intermediaries, would get probably 2 per cent and the farmer about 8, is pretty close to the figures, and I think that would be a fair idea.

Q. What is the duty, the 10 per cent ad valorem? Is that your proposition?—A. No.

Q. How do you intend to establish your export bounty?—A. I am not caring for that myself. It was only the idea, not the details of the matter. The bill, I think, provided for a bounty of about 5 cents on a bushel of wheat, a cent a pound on cotton, and probably a cent a pound on tobacco; but the bill before the Senate changed the estimate when it was under discussion. It is not so much what they get out of it by what goes out of the country as the immense increase of the prices inside of the country. The raising of the prices in the New York market 5 cents a bushel on wheat means 25 cents for every barrel of flour consumed in the United States, and the farmers are bound to get a big proportion of it. It may seem an absurd proposition, but it is really one worth careful thought.

Q. (By Mr. CLARKE.) Well, now, in view of the fact that experience proves that the export bounty of Germany on sugar causes sugar to sell at a lower price in England than it does in Germany, is there not some danger that an export bounty

on wheat and cotton would cause those American exports to sell at a lower price in the world's market?—A. Well, so far as cotton is concerned, we have got practically no competitor at the present time. The work is opening in the Russian Steppes, where in time I am afraid we will have a great competitor. In regard to the wheat question, I do not think really that it would, because it could not; prices are fixed by supply and demand. It goes into this bin in Liverpool, and there prices are fixed; but if it did I do not believe we have anything to do with that. It don't make any difference what it sells for in Liverpool, provided we can increase prices and increase the prosperity of the man with the hoe—the fellow with the reaper.

Q. That brings us right to the point I wanted to bring your attention to in the next question. In reducing the price in the Liverpool market, how would it be possible to maintain a higher price here?—A. If the price is decreased in Liverpool, the price will be decreased here, but still it would be just that much higher here in the home market than it would be in Liverpool; whatever the bounty was, 5 cents a bushel, or 10 cents a bushel, it would still be just that much more here than there.

Q. Well, would it be any more than it is now?—A. That is a problem that I am not able to answer. I think it would.

Q. Unless we can better our condition by an effort of that kind you would not favor it, would you?—A. No, I would not favor it; but as far as I have studied this question, and I have looked into it carefully for two or three years with all the facts and figures I could get, I am of the opinion that the price will be increased here, and that the price in Liverpool would not be decreased; and I reiterate that, because there is a demand greater than the supply, and the world's consumption of wheat is greater than the supply has been in good years, therefore the price is fixed in England—in Liverpool. All these different countries sending in their supply, and with the India surplus there, and England owning and controlling that India surplus, she is compelled to throw it on the market at such a rate, and buying it for silver as she does, rupee a bushel, that would bring up another question, which I do not care to mix in just now. She has bought it for 20 odd years with her rupee a bushel; do as she pleases with it, and being a consumer she wants to bear it down. That she can not do with the Australian people, but does do that with India, and that is the price that fixes the value of wheat in the English market, if I am not misinformed.

Q. (By Mr. A. L. HARRIS.) You may state, if you please, what is the effect upon the prices of farm products of what we call dealing in options and futures.—A. Well, I believe they are absolutely ruinous. I would refer you to another report of the House Agricultural Committee on that subject for a good deal more information than I could give you. I believe, if I have a right to come in here and offer to sell something I have not got, never expect to have, and everybody knows I have not got it—if I have got a right to sell it in competition with your 50 bushels of wheat, and I offer 500 at 10 cents less than you are offering your 50, you are bound to bring the price right down.

Q. You think it interferes with the natural law of supply and demand?—A. I certainly do. It not only affects the market for the day, but you sell 50 times as much, or 500 times as much, as is raised. Of course it would not have any effect for that day's delivery, but to be delivered 6 months hence or 30 days hence it would have an effect, because men have got to deliver that wheat, and they have always got to work to keep prices down to the date of delivery.

Q. Another factor is in trying to keep the prices up—another side?—A. Yes; but I do not believe that works. I have not studied the question so thoroughly and fully as other gentlemen, but the report submitted to the House of Representatives in the Fifty-second or Fifty-third Congress by the Committee on Agriculture covers that whole subject in, I think, a most admirable and thorough manner, and in it you will find that statement of the gentleman I mentioned a minute ago. Mr. Wood Davis.

Q. Do the farmers of Virginia complain about transportation rates?—A. Yes; they complain more or less.

Q. In what particular?—A. Well, they think they are a little too high, but I do not think there is quite as much complaint as there has been in the past.

Q. To what do you ascribe that change for the better?—A. Well, probably the lack of organization. They do not get together and do not talk over their grievances so much.

Q. I have reference to the railroads, the improvement that you speak of?—A. Well, the railroads have better facilities, slightly more competition, and, I believe, really there is a better feeling between the people of the State and the railroads than there was 8 or 10 years ago, and the managers are finding out that it is probably better not to antagonize the people so much; but still there is great room for improvement.

Q. In your experience as a newspaper publisher have you heard any complaints against the Interstate Commerce Commission?—A. Well, I have heard complaints against the commission, with a great deal of praise in a general way. Yesterday I heard a statement that probably astounded me a little, by a very large merchant doing a very heavy business.

Q. In this city?—A. No; in Alexandria; several hundred thousand a year. In a public assemblage the gentleman made this remark, that the Interstate Commerce Commission under its present arrangements, not having the control of its own matters, was perfectly valueless; that he knew of instances where railroads made contracts just as they formerly did—discriminated; that if a man knows how to manage he gets just what he wants, but you have got to know how. For example, I know of a man who contracted to have, I think he said, 100 barrels of flour delivered at a certain price, and packed 500 barrels in the car. I am not using the exact figures, but approximately. In other words, the railroads make contracts for delivery to large shippers without regard to the interstate-commerce law. They contract for a smaller amount, and allow the shipper to exceed the shipment without any supervision, practically knowing that he is doing it.

Q. Have you a remedy to suggest for that condition?—A. The only remedy I could suggest would be to give the Interstate Commerce Commission the authority to enforce its rules and regulations.

Q. Have you a pure-food law in your State?—A. No.

Q. Have you given the subject of pure food any study?—A. Yes; I have; I think I have devoted most of my time to that subject for nearly 10 years.

Q. Were you an expert in the employ of the Agricultural Department on that subject at any time?—A. I was appointed several times, as previously stated, to investigate the extent and character of food adulterations by the Department, and made reports numbers 25, 32, 40, and 41, of the Chemical Division, and a special report, Farmers' Bulletin No. 12, and a report that was printed, as stated previously, in regard to flour adulteration, by the Committee on Ways and Means in the Fifty-fifth Congress.

Q. Did you make any recommendations in those reports?—A. Yes; I recommended that a national law along the line of control under the interstate-commerce clause of the Constitution be adopted.

Q. Where would you lodge the authority to enforce that law?—A. Well, for various reasons I would lodge that enforcement in the Department of Agriculture, chiefly, because the Department of Agriculture has for nearly 20 years, under the authority of Congress, been investigating the subject. They have issued in what is known as the various parts of Bulletin No. 13, analyses and reports on various food products, such as wines, liquors, beers, canned goods, coffees, lard, oleomargarine, and other products, edited and conducted by the chief chemist of that Department, Dr. Wiley. It is recognized by scientific men all over the world, as far as I can learn, and certainly by all State representatives in the various State departments largely, and food commissioners, as the most extensive and best literature on the subject of food adulteration in the world.

Q. Wherein is the farmer more especially interested in preventing the adulteration of food than other citizens?—A. Well, he has a twofold interest. In the first place he purchases a great many of these products, and is a consumer of the products, and therefore he is on exactly the same footing as any other citizen. Secondly, the farmer is a producer or manufacturer of a large majority of the products, and consequently he is not only robbed in what he buys, but he is robbed in what he sells, and is in competition with the man who sells a product which costs him nothing in comparison with what it costs the farmer to produce it, and he has to sell his goods at the reduced price of the spurious article or not at all. For example, they adulterate the honey. The farmer has to produce that through the instrumentality of the bee—the work of the bee. Well, the manipulator simply uses a little glucose and a small quantity of honey to flavor, one being worth probably 25 cents and the other 2 or 3 cents a pound. Take a can of jelly, pure jelly produced by the farmer or by the manufacturer of pure products from a pure fruit. That is an article used upon nearly every table and can only be sold at a reasonably fair price, probably \$1 or \$1.50 a bucket, while the mixture sold by adulterators is offered upon the market at 25 cents to 30 cents a bucket. This product of course reduces the value of the true product, and has driven it to a large extent from the market. It is made of refuse, parings and cores, sweetened with glucose, and where raspberry and strawberry seeds are wished to be imitated a few timothy seeds are put in their place and are used to supply these deficiencies. We might take the articles of coffee, spices, or any other product, because I do not believe, after careful investigation, that there are hardly a dozen products that are capable of imitation that are offered for food that are not imitated.

Q. What about lard?—A. Oh, lard is very largely imitated. They use instead

of hogs' lard, cotton-seed oil, stearin made from beef or hog grease, and use inferior lard to mix with these articles, the cotton seed being the product that is used to sweeten the mixture and make it palatable. In the Fiftieth and Fifty-first Congresses a full investigation was made on this subject. A bill passed the House regulating it, but it never passed the Senate.

Q. Are there any adulterations of butter?—A. There are few articles that are more adulterated than butter. The farmer produces a product that costs time and care, while his competitor in making oleomargarine furnishes a product that costs probably one-third what the real product does. And then the farmer also has to meet the manufacturer of butterine and of renovated butter; and there are a great many nostrums on the market offered to ignorant people to increase the yield of butter, some of which are very injurious. In Bulletin No. 12 the subject was fully explained and the crime traced to its founder, and I learned that the party was finally sent to the penitentiary. I do not know that to be a fact, but I understand he was caught out in Ohio and sent to the penitentiary.

Q. Are adulterations on the increase or decrease at the present time, do you know?—A. I am not sure. They are not decreasing very rapidly. I think that the agitation of the subject has probably made the adulterators a little more careful. The estimate that I gave to the Department of Agriculture, and which has never been controverted at all, was that about 15 per cent of adulteration is fraudulent adulteration and 2 per cent is injurious adulteration of the entire product—food and drugs. These figures, I believe, have been generally accepted by the State officials as conservative. Now, during my last work at the Department, my letters from every State in the Union have indicated that it was double that amount; but people are liable to be extravagant in their estimates, and I retain the original figures. I believe that they are fairly conservative. Now, I would like to call your attention to this fact, that 15 per cent does not appear to amount to a great deal, and yet if you estimate that the people of the United States number 75,000,000 and consume only \$2 a week per capita, you will find that it amounts to \$150,000,000 in a week, or \$7,800,000,000 a year, and the cost or loss to the country has only been \$1,117,000,000 a year from fraudulent adulteration, and very injurious adulteration \$156,000,000. Those figures are absolutely conservative. They were discussed in the National Pure Food and Drug Congress, composed of 200 or 300 eminent scientists and men representing nearly every State food and dairy commission and many health officers, and, as I stated above, have never been controverted. It seems to me that the Government of the United States ought to take some steps to save this immense loss to the people. I do not wish to be understood as stating that the whole \$1,170,000,000 is loss, because, of course, a great majority of the products are what you would call fraudulent adulterations. They are frauds upon the pocket, and not upon the health. But, for example, where flour and meal or flourine are mixed there is not a loss of all of it, and the percentage would not be borne out, because the corn grower gets a part of the profit. There is a demand for that much more corn, but the loss falls upon the wheat grower. It is just that much loss to the wheat, and the price is depreciated to that extent. But the loss must run into \$700,000,000 or \$800,000,000 a year.

Q. So far as the flour is concerned, Congress has taken action on that.—A. The same as it has in filled cheese. Now, some people suggest that we should have a separate law for every article. It would be absurd to talk about it. If you should tax every article we would have more money than we knew what to do with. The Government should have a standard for every article. There are thousands of different grades. All that I should like to see done would be to have every article branded as to what it was made of. That, I believe, is the desire of the National Pure Food and Drug Congress.

Q. Have you anything else that you desire to state from your standpoint, as a representative of agriculture, to the commission?—A. No. I am very much obliged to you gentlemen for your very patient hearing and allowing me to answer all of these questions, and I hope I have not been too tiresome. But there are some points that I feel a deep interest in, especially the discussion of this food question, and if your commission could in any way influence Congress to pass a law that would put a stop to the false branding of products in this country you would be doing an immense amount of good.

Q. Has any effort been made in your State to have a pure-food law?—A. Yes; there have been several efforts, but I have never taken any part in it, for the simple reason that our legislature has always met during the session of Congress, and since the Fiftieth Congress I have been here trying to get this law. I have never had any pay and I am not in the shape of a lobbyist, but I am just a kind of a crank on this subject, I reckon. I have done it in the interest of my paper, making it a specialty to do all that I could.

(Testimony closed.)

DEPOSITION OF ADOLPH GEHRMANN, M. D.,

Director of Laboratory, Department of Health, Chicago.

As any community grows in size and importance, and as larger quantities of food material are consumed in any given locality, there immediately comes to be observed in that place a tendency upon the part of dealers to make use of under-hand methods in competition with one another, and to prey upon the transient customers by using methods of adulteration and sophistication of food materials.

This condition of affairs continues and grows gradually, until after a time the entire community comes to realize that it is being systematically robbed and that the evil is slowly increasing. It is then that agitation occurs and food laws with their regulations are established.

As I have been especially interested in the milk supply of Chicago during the past few years, I desire to present a few facts that have been learned during the time that the milk question has been under consideration in Chicago.

Supervision of the quality of milk offered for sale in Chicago was established by a city ordinance passed October 21, 1892. This supervision was transferred to the department of health in September, 1893.

During 1893, out of 8,926 samples analyzed, 4,053, or more than 45 per cent, were found below grade. The first 500 samples were taken at railway depots immediately on arrival. Of these only 41 samples, or 8 per cent, were below grade. Of the next 500 samples collected—taken from dealers' wagons—374, or 75 per cent, were below grade.

This showed that at that time "the work of adulteration was chiefly done by the city dealers." See annual report of the department of health for the year 1893, Arthur R. Reynolds, M. D., commissioner of health.

The diagram on page 636 shows, by months, the results of this supervision, beginning with January, 1894.

The rise in the percentage curve of below-grade samples in February, 1894, was due to the taking of a large number of samples of milk in the poorer parts of the city, where skimmed milk was being extensively sold.

The steady fall of the curve during the rest of this year is due, July excluded, to persistent prosecution of offenders. The marked decrease during July was caused by a decrease in the total number of samples collected, owing to vacations allowed to the milk inspectors.

In 1895 the increase in the percentage of poor samples during the first five months was due to the inability of the department to secure prompt prosecution of offenders during that period.

The fall of the curve from May to September is attributable to publication in the daily press of the names of those whose samples were found below grade, without awaiting the result of prosecutions.

The minor rise during December, 1895, was caused by the enforcement of the prohibition of the use of coloring matter in milk and cream. Previously the use of coloring matter had not figured in the percentage of samples not in accord with the ordinance standards.

The variations of the curve during 1896 are mainly due to the extension of the inspection into new parts of the city, as in October, November, and December of that year, when outlying districts—South Chicago, Pullman, and Rogers Park—were brought under inspection.

The rise of the curve to 12.5 per cent in September, 1897, was occasioned by the "milk famine," caused by the prolonged dry weather. Milk dealers resorted to watering and other adulteration to eke out their short supply, and the result is apparent in this rise.

The principal causes leading to the practice of adulteration are to prevent loss to the owner of the goods when they remain on hand unsold. An attempt is then made to preserve them, so that they may be presented in good condition at some future time. Competition is a most pertinent reason. This is especially true when food stuffs are high priced, because then dealers do not wish to lose their customers and will at once try to meet the prices made by their competitors.

Outside of adulterations the meat question deserves special attention. This is required because a carcass from a thoroughly diseased animal may be so dressed and hung up for exhibition that only expert scrutiny will show from what character of animal it was obtained. A strict supervision of meat is required from the very moment that the stock arrives in the yard of the slaughterhouse until it is sold to the customer. The greatest danger here is that diseased conditions will

be overlooked, or that one carcass may be substituted for another, or that decomposition more or less marked will develop because of uncleanness in handling the meat.

All laws which are enacted for the protection of the public in their food supply should embody as principles certain conditions which I believe would lead to a much wider range of usefulness than is covered by many laws now in force. They should be extremely explicit in regard to the quality and quantities of constituents of foods. Generalities of laws of this kind always require interpretation before they can become legally effective. The condition therefore arises that a different interpretation is made by one administration after another, in consequence of which dealers are placed at a disadvantage and the public does not know what to expect. I should consider it highly important that food laws should be uniform throughout the various States and cities, with only such allowances as territorial conditions might demand. An addition of great advantage to all food laws, and one that is overlooked in many cases, is the requirement demanding cleanliness in the production, handling, and storage of all food stuffs, not alone those which are perishable, but those which are of a staple quality.

It has been my experience, from an extended acquaintance with public inquiry in regard to questions relating to pure food, that but a very small portion of the general public knows anything of the laws that are in force, or the rights given to the citizen under such laws. It would therefore seem proper and highly desirable that a much more extended knowledge of pure food matters be disseminated among the general public. As an instance of this condition I might recite frequent inquiries in regard to the substitution of butterine for butter. Scarcely one of the persons calling for information on this subject knows the regulations in regard to the use of signs, stamps on packages, and size of packages which are part of the law regulating the sale of butterine in shops.

After a good food law, the next important necessity is an adequate administration of the law. In most localities the first mistake that is made after a good law is framed is that its enforcement is then placed in the hands of an entirely inadequate number of inspectors. When one takes into consideration the total value of foods bought and sold per day in average cities, or per capita in States, it at once becomes apparent that scarcely any State or community in the Union has a corps of inspectors to regulate this business in any way proportionate to the value of the articles bought and sold.

Inspectors employed for the inspection of food should be persons of average intelligence. They should be interested in their work; they should not follow out their duties simply because they have the position, but should be stimulated so that there is an actual interest in doing the work properly. This work is not like the average occupation, where so much labor is laid out for the individual to complete during the day. A food inspector has a wide range. It is necessary for him to make a start at some point and to follow any opening which may lead toward the discovery of fraud that may present itself. His intelligence, his adaptedness and interest in the subject, will show him these chances, while to another man they would be lost.

The selection of a chief executive for the enforcement of food laws is most important, and there is often some discussion as to whether a business man or a scientific man is best qualified. The special qualifications of both should be combined, but the business man should predominate. A good executive, with ability to see and appreciate the importance of small occurrences, will be able to develop most out of the information which comes to hand.

Probably the greatest difficulty in the administration of food laws is the interference which comes through political or personal relations after suits are instituted. This frequently causes an added expense to the department of inspection, in that cases are dismissed and the cost of service and court fees fall upon the city. All cases for the violation of food laws should be fully tried, and the defendant should be given every advantage of a thorough hearing. I have found that every case that has been contested and has resulted in a thorough trial on its merits has added points which have given strength to the law under which it was tried.

It should also devolve upon courts that fines imposed should be collected, but beyond this the public has a means of redress which is more feared by offending dealers than any fine, and that is through publication of those prosecuted and found guilty in the daily press. There is probably nothing which will more quickly bring offending dealers to terms than notice of their offense in the newspapers.

ADOLPH GEHRMANN, M. D.

STATE OF ILLINOIS, *County of Cook, ss:*

Before me, Daniel C. Appleton, a notary public in and for said county and State, personally appeared Adolph Gehrmann, whose signature is above written, and made oath to the truth of the above and foregoing statements.

Witness my hand and official seal this 12th day of July, 1900.

[SEAL.]

DANIEL C. APPLETON, *Notary Public.*

WASHINGTON, D. C., *May 14, 1900.*

TESTIMONY OF DR. HARVEY W. WILEY,

Chief Chemist, United States Department of Agriculture.

The commission met at 10.30 a. m., Mr. A. L. Harris presiding. At that time Dr. Harvey W. Wiley was introduced as a witness, and, being first duly sworn, testified as follows:

Q. (By Mr. A. L. HARRIS.) Please state your name, post-office address, and occupation.—A. Harvey W. Wiley; post-office address, Department of Agriculture, Washington, D. C.; occupation, chief chemist of the Department of Agriculture.

Q. How long have you occupied that position?—A. Seventeen years.

Q. In that time you have given some investigation to the question of the beet-sugar industry of this country, have you?—A. Yes; from the start I have made that one of the chief studies of my division—the division of chemistry.

Q. You are acquainted with or have information of that industry in the different portions of the United States, have you?—A. Yes; in all parts of the United States and in all parts of Europe. I have made two or three trips to Europe and have investigated the conditions of the beet-sugar industry there.

Q. Have you any further statement that you desire to make preliminary to the beginning of your testimony before the commission?—A. I will state that the Department of Agriculture for many years before I was connected with it was interested in this matter. The first investigations which I can find mentioned in the records of the Department were made in 1862 by the first chemist of the Department, who had then just been appointed. He made analyses of sugar beets at that early period. The first attempt to introduce the sugar-beet industry into this country was made in 1835 by an association of agricultural and scientific men of Philadelphia. They employed a gentleman to visit France, at that time the only country making any notable quantity of beet sugar, and he visited that country and made an elaborate report on his investigations of the beet-sugar industry. As the result of his investigations, an attempt was made at Northampton, a year or two after that to grow beets for industrial purposes and sugar making, and several hundred pounds of sugar were made, but the industry did not get any hold at all at the time. However, it continued to grow in Europe, having been established as an industrial occupation by the first Emperor Napoleon.

The conditions which prevailed at that time are well known to the commission. On account of the embargo which England laid on European ports, the colonial sugar was practically excluded from France and the whole Continent of Europe, and it was to remedy this defect that the Emperor made a grant of money in the form of a subsidy to encourage the establishment of beet factories in the Empire. This was about 1809 and 1810. Of course the fall of the Emperor 2 or 3 years after that interrupted the State bounty, but nevertheless the industry had taken such a hold in France that it continued to grow after the State subsidy was withdrawn, and by 1830 France made a very considerable quantity of beet sugar—to be sure, a small quantity compared with the present production, but a very large production as measured by the markets of that period.

The Germans, who had been the first to discover the merits of the beet as a sugar-producing plant, were not slow to follow in the pace that the French had set; and such apt scholars were they that by the time of the third Emperor Napoleon, especially toward the end of his career, along in the latter part of the decade beginning with 1860, the German production had quite overtaken that of France. Since the great war of 1870 and 1871 the German production has forged ahead until now it is almost double, or quite double, the production of France.

A few figures will show the wonderful growth of this industry which has taken place in Europe. At the present time the total production of sugar in the world is probably 7,000,000 tons, and of that quantity more than 4,000,000 tons are pro-

duced from beets; so that considerably more than half of the sugar which is now produced in the world is beet sugar, and this is practically all produced on the Continent of Europe. There is so little being made in other countries as to be of very little consequence in the sum mentioned.

The beet itself is a plant which is indigenous to the European shores of the Mediterranean, and all of the varieties which are now used for beet-sugar production have been developed by selection and cultivation from the *Beta vulgaris*, which is the botanical name of the original beet growing wild along the European shores of the Mediterranean. The beet itself, in its wild state, is an annual plant, producing seeds from seed the first year. When carried to the north of Europe, however, and placed under cultivation it became a biennial plant, the seasons not being long enough in the north of Europe to produce the seed.

This is the real keynote of the success of the beet as a sugar-producing plant, because the very moment it begins to produce its seeds or seed stems that moment the store of sugar which it has put away begins to be consumed, and the beet becomes pithy and woody and loses its sweetness very rapidly; so if the beet were still an annual plant the production of sugar on a commercial scale would not be practicable.

The tendency to reversion, however, is still very marked in the beet as you go south in Europe. If you look over a field in Germany in the autumn or harvest, you will probably see one plant to every two hundred which will still adhere to its original habit of producing seeds, and you will see the seed stem running up, not maturing but being formed so that the beet is less sweet. As you go into France, which is farther south, I have myself seen as high as 5 per cent of the beets in a field producing seed, so that in looking over it it appeared as if practically a great many had run to seed. This, however, is not of sufficient magnitude to interfere very greatly with the sugar content.

This general principle is true not only in Europe but in this country, that the farther north you go the richer the beet will be in sugar, provided the season is long enough to bring the beet to its first stage of maturity; that is, to the time when it is ready to produce its seed. Now, there are two reasons for this; in the first place, the cooler summers do not ripen the beets so rapidly, and the tendency to seed production is thereby repressed; in the second place, the production of sugar is the joint function of warmth and sunlight, and as you go farther north you get longer periods of sunlight during the growing months, and hence a given surface of leaf, for instance, represented by that square [indicating sheet of paper] will produce more sugar because it works longer, just as a workman working 14 hours will do more work, other things being equal, in the same occupation, than he will in 10 hours. In the north of Europe the beet will work 16 hours in June, and it will do the same amount in each hour.

As you go farther south the hours of sunlight are diminished, and the amount of sugar product is lessened. For this reason in Russia the finest beets grown in Europe are produced. The farther north in Russia that beets can ripen at all in the first stage the higher the percentage of sugar. So in the growth of beets for sugar those sections having the longest days in the growing season are the best adapted to produce the richer beets. I will develop that fact a little farther along, when I begin to apply to it the investigations made in this country.

To go back again to the first theme brought out—the relation of the Department of Agriculture to this industry—I will say that the first systematic work which was done by the Department toward promoting the industry in this country was accomplished during the Exposition in Paris in 1878. Dr. McMurtrie, who was at that time chemist of the Department, was detailed to go to Paris in charge of the exhibit from this country, and was charged with studying the beet-sugar industry with a view to its introduction into the United States. He made a very elaborate report and a very valuable one, which has become a standard in this country, and supplemented it with investigations the next year in this country.

As a result, indirectly, of this investigation capital was largely interested in the industry along in 1879, 1880, 1881, and 1882, and quite a large sum was invested in different parts of the country, especially in the New England States and in Delaware. In Delaware a large factory was built which at that time had all the modern improvements, brought fully up to date. Another was built at Franklin, Mass., of elaborate construction, and the third in Portland, Me.

Soon after becoming connected with the Department I visited all these factories, not then in action, and had an opportunity of looking them over before they were demolished. They were all beautifully constructed of the most approved machinery known at that time, and, so far as manufacture was concerned, should have been a success. All these ventures, however, resulted eventually in disaster and solely from the agricultural side. That has been the history of the industry

ever since. From the point of manufacture, we have always kept abreast in this country, and ahead. I will say that to-day we have the best beet-sugar factories in the world, and experts are coming from all over Europe to study them. We have gone far ahead of European constructors, but we are still far behind in the agriculture of the beet, and for reasons which will appear as I continue.

In 1884, the year after I became connected with the Department, I was instructed by the Commissioner of Agriculture to study the remnants of the sugar-beet industry in this country to see if anything could be done toward reviving it. I visited these localities, as I have stated, and also went to California, which at that time had the only active factory which had remained over from the impetus given in 1878 and 1879, which I have mentioned.

I made at that time a report, which I will refer to here, and which can be cited in your records, or referred to at least. This report of my observations in 1884 is found in Bulletin No. 5 of the Division of Chemistry, pages 73, et seq. The only factory which was in operation at that time is here represented from a photograph which I had taken under my personal supervision during my visit. It was situated in Alvarado, Cal., about 15 miles south of San Francisco.

Here was one instance where agriculture had gone ahead of manufacture. This was a small factory, capable of handling only 80 tons of beets per day; but the farmers had taken such an interest in the matter there, and it had proved so profitable to grow beets in that valley that they had overwhelmed this factory with beets, and over 20,000 tons of beets were lying in one pile there. The factory was almost hidden with such a wealth of beets.

Q. (By Mr. SMYTH.) You stated that the American sugar-beet factories were much superior to those abroad. Why is that?—A. It is because our constructors are quicker to adapt themselves to the exigencies which arise than are the European machinists. In Europe anything that gets started once is followed almost blindly. They do not have the inventive and adaptive faculties which our engineers have.

Q. The American engineers improved on the system of the beet factories?—A. They improved on the system—made a better machine and made it better suited to our conditions here. I will say that a great many of our machines made in this country are now used in Europe, particularly our centrifugals or drying machines. They are recognized everywhere as being the best in the world, and you will find them in nearly all the larger and especially the newer factories to-day. It is not the only reason, but it is a very marked one, why our constructors are superior. They can adapt themselves more quickly to the circumstances which arise than foreign constructors do.

Q. (By Mr. KENNEDY.) Is it true also that European machinery is being imported into this country?—A. To a very little extent; almost none now. When the factories first began—those I mentioned as having been built in Massachusetts, Maine, and Delaware—every piece of machinery which they contained was imported from Europe. Some of the best factories in this country to-day have not a stick of machinery imported from Europe, and I doubt if there is any new factory made entirely of new machinery that is wholly European to-day that has been built within the last few years, although there are some forms of machinery still imported, like the slicers, for instance, that cut the beet up for the extraction of the sugar; but our boilers, our centrifugals, evaporating pans, vacuum pans, and our driers are all of domestic manufacture. One of the new factories built for the crop of 1899 and 1900 was equipped almost entirely with imported machinery, but I am informed that a very considerable part of this machinery is being replaced by American machinery for the crop of 1900 and 1901.

Q. (By Mr. SMYTH.) Are the factories larger, as a rule, than those in Europe?—A. The average size of our factories is larger than in Europe, and we have the largest factory in the world.

Q. Do you consider that we manufacture the sugar cheaper than in Europe?—A. Well, we pay a great deal more for labor. With the American machinery the labor is so much more efficient, and our fuel is so much cheaper and more economically used, that I believe we save practically in these ways what we expend over and above what the Europeans pay their labor. So I believe, for that reason, we can make beet sugar almost, if not quite, as cheap as it is made in Europe to-day, although we pay more for beets and more for labor than they do there—far more.

Q. (By Mr. KENNEDY.) Where is the largest factory?—A. The largest factory is in Salinas, Cal. It has a capacity of 3,000 tons of beets per day. Compare that with the first one in California of 80 tons, and you will see the force of the comparison.

Q. (By Mr. SMYTH.) Are these factories engaged throughout the whole year, or a short season?—A. Only from 60 to 120 days.

Q. And then they shut down?—A. Then they shut down.

The investigations which I started there have been continued ever since in the Department of Agriculture, and I will just give you a citation of the reports which have been published relating to it. The report which I have just mentioned was published in 1885. The next one contains the results of investigations made in 1890. During this interval investigations were made on beet sugar and other subjects. In 1890 we began another series of special investigations, with special reports, and this is Bulletin No. 30 of the Division of Chemistry, being the results of experiments made at Schuyler, Nebr., on the subject of the production of high-grade seeds.

While I am on this point I might as well develop what I have to say on that industry, which is a very important one in connection with the growth of sugar beets. You will understand that the beet is grown from the seed. The beet having become a biennial, does not produce other seeds for two years, and the whole development of the beet in sugar content has been accomplished by what we call selection; that is, beets which are exceptionally favorable for sugar production are selected for mothers. They are put away in silos during the winter, so as to protect them from frost. They are one of the earliest plants set out, because light frosts do not hurt them. In March or April they are set back in the ground in rows so they can be cultivated, and then they produce their seeds, which ripen in August.

Q. Would they be killed if left in the ground?—A. They would be killed. Freezing and thawing would entirely destroy their vitality.

Now, to produce high-grade seeds the following method is pursued, and it is the method used in these experiments which continue over a period of three years. This is the first report. Beets are grown in the usual way from ordinary seeds such as are planted for producing beets for the factory. From these, beets typical in shape and size and perfect in form are selected, as many as you desire, sometimes about a thousand, and they are carefully preserved over winter. In the early spring the silos are opened, and each one of the beets is subjected to a chemical analysis. You can take a sample for analysis without destroying its vitality, and for doing that we take a core. Bore diagonally through the beet a core, say an inch in diameter and take the pulp out. By going diagonally through you get a representative sample of the whole beet, because the sugar is not evenly distributed. Near the top there is less than in the center, and it is necessary to have a diagonal core in order to get an average representation of that beet. This core is subjected to an analysis, and the amount of sugar which it contains is determined. If it is a poor beet, containing 12, 13, or 14 per cent of sugar, we throw it away or use it for cattle food—reject it altogether. If, however, it shows 18 per cent of sugar, that is a very high grade, and we place it in that grade. If it shows 17 per cent, we put it in another grade; if it shows 16 per cent, we have another grade. In this analysis we separate these beets into four grades. One we reject, that which falls below 15, and then we have a grade of 16, one of 17, one of 18; and we rarely get a beet above 18. These beets are planted separately by grades.

Q. After they are bored?—A. Yes.

Q. It does not destroy the vitality?—A. Not at all. Of course the beet becomes a little injured, but there is still enough plant food to produce seed, and we go on the theory that like produces like; that is, the theory of evolution. Being rich in sugar, it will tend to produce seed which will produce other seed which will produce other beets that are rich in sugar.

Following that plan the beet plant has been developed from a plant containing 5 per cent of sugar to a plant containing an average of 15 per cent. That has been done in the last 100 years, and beets are still improving; but you will understand there is a limit beyond which we can not go, and that has been practically reached. It is doubtful if we can produce richer beets unless we can get a better grade of beet, like northern Russia. So we can still make some improvements and hold that which has been obtained, and not go backward. The moment the beet is neglected it begins to degenerate. It is that atavism—that tendency to go back to the type of its ancestors, just as human beings do if the opportunities of culture are taken away from them. We would all go back to barbarism if left without culture. Now, the great effort is to hold the beet up to that high grade, and that was the object in this country—to determine what could be done here in producing a high-grade beet and in holding it up to its standard.

These selected beets are planted. They produce seeds that year. These seeds are harvested and planted the next spring, and the second year we get another crop of beets. They do not come up to the pattern—some may be very inferior—but the tendency is that beets grown from a mother of a high grade will be richer

in sugar than beets grown from a mother of low grade. That has been frequently established by actual demonstration. The general tendency of the average is to be higher. So by going on patiently from year to year we have secured a type of beet seed which will grow over a whole field, under favorable conditions, a commercial beet which will have an average of 15 per cent of sugar.

Of course you understand we could never plant these seeds from analyzed mothers commercially. They could only be used for growing seeds the second, third, and fourth year. Beets grown from analyzed mothers' seeds would be worth \$5 a pound. But that one mother will produce the second year a hundred beets, and if you plant those beets they will produce seed enough to produce a whole field full.

Q. The practice of growing and testing seeds is only done in your Department, not done in the agricultural regions by the farmers?—A. No; but it is also done in the experiment stations which are devoted to the development of high-grade seeds. All the high-grade beet seeds to-day have been produced from analyzed mothers, but in the fourth generation only, after the growth of 2 crops. For instance, you order from a seed grower to-day in Europe a ton of beet seeds. These are grown from the mother produced 4 years ago and analyzed. No analysis has been made of these beets, but it is taken for granted that the seeds partake of the nature of the mother from which they were produced.

By authority of Congress a station was established in Nebraska under the control of the Department of Agriculture, which I had charge of as director, to do in this country what had been done in other countries, and especially to see what particular influence the soil and climate of the United States would have upon the production of a high-grade beet. We thought possibly we might be able to produce a beet which, under our climatic conditions, would be better adapted for growth in the United States than one produced under dissimilar conditions in Europe, and although this station was only continued for 3 years—which was not time enough to develop the idea—we did prove in the 3 years that seeds grown by ourselves under these conditions, when planted side by side with imported seed of the same character, produced in this country beets having an average of 20 pounds of sugar more per ton than those grown from European seed, which was a perfect demonstration of the fact, which will soon be recognized by our beet growers, that we should produce our beet seeds here, even if it be by a costly process.

This station was discontinued at the end of 3 years, and no further attempts have been made by the Government to grow high-grade seed, nor has any private individual or firm engaged in this business up to the present time. The result is that practically all of the beet seeds which are planted in this country to-day are imported from Europe, because no one has seen fit to undertake this very costly process.

Suppose a body of capitalists would start in to grow high-grade seeds for commercial purposes. They would have to invest a large sum of money, and it would be 4 years before they would get a dollar in return; and our people are always slow to invest in any enterprise in which they are absolutely certain to have to wait 4 years for a dividend. Hence we have never had established here a seed farm such as are found in many places in Europe. I have visited some of the largest and best seed farms in Europe where they do nothing but produce high-grade seeds.

Q. These are run by private parties?—A. Yes; because it is a very profitable business.

Q. Do any of the governments maintain seed farms?—A. The government maintains seed-control stations, which work is done entirely independent of private corporations and where experiments are conducted at the expense of the government. This is true of every European government, especially of Germany and Russia, and to a less degree in Austria and France. The German seed-control stations are about 15 in number, where they do nothing but determine experimentally the methods of improving the quality of the seeds, not only of beets, but of other plants. That is entirely independent of the private corporations that grow beet seeds for the trade. In other words, the beet grower of Europe does not grow his own seeds, because he could not bring to the production of seed that scientific experience and ability which are necessary to hold the beet up to its high standard and improve it little by little as circumstances may warrant, and therefore all beet growers buy their seed of these great farms that devote themselves exclusively to its production.

Q. The farmer beet grower buys from these same parties?—A. Yes; such as Vilmorin in France and Ad. Strandes at Zehringen, and the great Kleinwanzlebener. They are perhaps the most extensive beet farms in the world.

Q. (By Mr. CONGER.) How many acres do they contain?—A. Ad. Strandes,

where I spent a week 2 years ago, has about 1,000 acres devoted to the production of seed alone, and the Kleinwanzlebener farms are larger—perhaps 6,000 acres.

Q. (By Mr. A. L. HARRIS.) Would it be advisable for the Government to give further encouragement to these investigations? A. I think it would be very advisable for it to continue the work we did here to demonstrate how the seeds can be produced, but not to produce them commercially—nothing but experimentally. I am opposed to the free seed distribution of the Government. I think it is a bad principle. But undoubtedly it is the duty of the Government to do that work which no individual can or will do, because it is simply an expenditure of money without any possibility of any pecuniary gain; such work as we started here to determine the effect of soil and climate and take advantage of any good effect which they would produce.

Lawes and Gilbert in England are the only private parties who have devoted a fortune to just such a work. It is a very praiseworthy thing for a wealthy man to do, but very few choose to do it. In fact, I think that is the only instance where a man has given his entire fortune without any hope of pecuniary gain. Sir John Lawes has given his whole private fortune practically, amounting to over \$500,000, in trust, to continue this work which he has conducted for 60 years in conjunction with Sir Henry Gilbert, who has given his life service, in conjunction with Lawes, to this work.

But, in the absence of any such munificent private endowment, it is the duty of the Government to promote the interest of agriculture, not only in the line of beet seed but also every agricultural crop.

For instance, the Secretary of Agriculture is now conducting a research, which he has committed to my care, which arose from the fact that complaints were made by millers established on the Pacific coast that their wheat which they were grinding would not make macaroni as it did a few years ago. In San Francisco the making of macaroni is a large industry because there is a large Italian and other foreign population which uses this food a great deal, and the Pacific wheat a few years ago made an excellent article. On investigation we find that the content of gluten in the wheat has fallen so low that it is no longer suitable for making macaroni. Now, the question is what is the influence of soil and climate on the gluten content of wheat, which you know is the most valuable constituent of wheat. Now, that is an investigation which a wheat grower or a miller would hardly be willing to undertake, and if he were willing he would not have the scientific ability probably to carry it out, but it is one where the Agricultural Department, in the interest of agriculture as a whole, can exercise a wonderfully good influence and do a good work, by pointing out the causes which produce this depreciation and, if possible, suggesting remedies so that the wheat can be restored again to the condition where it will be more valuable for that particular purpose.

Now, I will say in the sugar-beet industry that the development of high-grade seeds in this country must follow, because, from a merely pecuniary point of view, we can not afford always to import our seeds. They are worth 10 cents a pound delivered in this country by the cargo, not in retail but wholesale. The seeds which we distribute from the Department of Agriculture cost on an average 10 cents a pound. At least 20 pounds per acre should be planted, and where there is anything like bad conditions at the time of planting, more; because it is highly essential to the growth of a good crop of beets that they should be thick in the row. If there are spaces like this [indicating], the beets on the end will be overgrown, and overgrown beets are never so rich in sugar; and so to prevent overgrowth we have a beet every 6 or 8 or 9 inches in the row, and to do this we have to plant a great many seeds more than enough to produce this result.

A beet seed is an aggregation of seeds. One seed contains 4 or 5 seeds wrapped up together. If they would all germinate from every seed there would be 4 or 5 sprouts, but on account of their high artificial character they have a low vitality.

Now, this is another universal principle, that the more you develop a plant or animal the less power of reproduction that plant or animal has. The reproductive powers are the vegetative powers, and when you develop other qualities you diminish the reproductive strength. The cultured nation or family does not have as many children as the one lower down the scale. There is always a tendency to develop the plant or animal out of existence, and so the beet seed has a low vitality. A great many of them produce no sprouts at all, and of those that have 4 or 5 points that ought to produce sprouts, maybe only 1 will germinate, so you have to plant them very much thicker together than if they would all sprout. Hence the actual cost of the seed, without counting the cost of putting it in, is probably \$2 an acre. That means a considerable sum where thousands of acres are planted. I suppose we spend—say we have 100,000 acres planted in beets in this country—at least \$200,000, which we are sending out of the country each year

for these high-grade beet seeds and, of course, as the industry increases, that will become a sum of great magnitude, and we must look forward to the time when the seeds will be produced at home.

Q. (By Mr. CLARKE.) Is there any beet seed farm anywhere in the country?—A. None whatever. There are places in California where they grow seed in a haphazard way without analysis, but if that practice is continued the content of sugar will run right down, because there is no control to hold these beets up to their standard.

Q. No analysis made?—A. No analysis made, and without this control degeneration will immediately set in, and the people who use these seeds will be out of the race because they can not compete with those who use the high-grade seeds.

Seed production from an industrial standpoint is one of the very greatest importance in connection with the beet industry. It requires the highest degree of skill and labor and the greatest amount of patience of any agricultural profession.

Now, continuing the result of our investigations: Following the report of Bulletin 30 comes Bulletin 33, which gives a continuation of the experiments at Schuyler, Nebr.; and Bulletin 36, which contains the result of the work the last year that it was conducted.

I might say this work was not discontinued for lack of an appropriation on the part of Congress, but the Secretary of Agriculture who took office in 1893 did not believe in any kind of paternalism, and he thought the growth of seed was "paternalism gone to seed," as he expressed it. So, although Congress had made the appropriation he abolished the station and sold all our appliances, and the station has never been restored. This bulletin gives the result of the last year's work, and shows the fact which I mentioned, that the beets grown from seeds which we ourselves produced gave a result which was very encouraging, and that the growth of our own seeds in our own climate would prove of the greatest pecuniary advantage in the process of manufacture.

Now, I think I have said enough in regard to the seed production, and I want to bring up next the studies we have made in regard to the distribution, or the location rather, of the area in this country where beets grow best. It has seemed to the Department of Agriculture that it was its duty to aid intending investors, at least in a negative way, by showing the parts of the country where it was probable they would get the best results from an agricultural point of view. We have never taken up to any extent the manufacturing side—that is, the location of factories in regard to coal and water transportation. We have studied always from the agricultural side—that is, where can you grow the beets best?

Now, acting on the idea which is so patent in Europe, that northern latitudes produce beets of the highest grade, it occurred to us that we would naturally find in this country our best beets grown along the northern borders of our country or somewhere in that region. In other words, that the farther north we could go and get a climate which would produce a crop suitable for manufacture, and get ample time before the advent of winter to harvest that crop and deliver it to the factory, the better the character of the beets would be and the more likely the industry would be to succeed.

But we did not act on that theory exclusively. We exploited every part of our country. We sent seeds to agricultural stations in every State, with instructions for cultivation, because the planting and cultivation of beet seeds must be conducted according to special methods—that is, ordinary agricultural rules will not apply to beets. It is horticulture rather than agriculture; and in order that all parts of the country might be fully represented we had a uniform system of directions for all parts. Not only did we send to the agricultural stations, but to farmers in all parts of the country who were interested and who would promise to conduct the work according to our instructions. We have distributed in the last 10 or 15 years to an average number of 6,000 farmers in different parts of the country every year, and to all the experiment stations desiring to collaborate in this work.

So far as possible we have had the analyses made at the experiment stations of the States so as to avoid long transportation of samples; but we have also always had our own laboratories and have every year made many analyses of samples sent from all parts of the country, so we have had checks on the work done in the different localities. This work has been continued more than 10 years, and we think the data accumulated in that time are valuable. They certainly are unbiased and have been obtained under as nearly as possible uniform conditions. The result has fully corroborated the theory of the culture here, and as a result we have been able to construct a provisional map of our country (herewith reproduced; see next page) showing at least the southern limit of probable profitable culture, but without trying to extend it to the north, because, as I have said, there is no limit to the north except the winter.

Q. Allow me to ask if you are familiar with the culture of the sugar beet in Canada?—A. Yes; fully.

Q. Is that business successful there?—A. The trouble there is the difficulty of

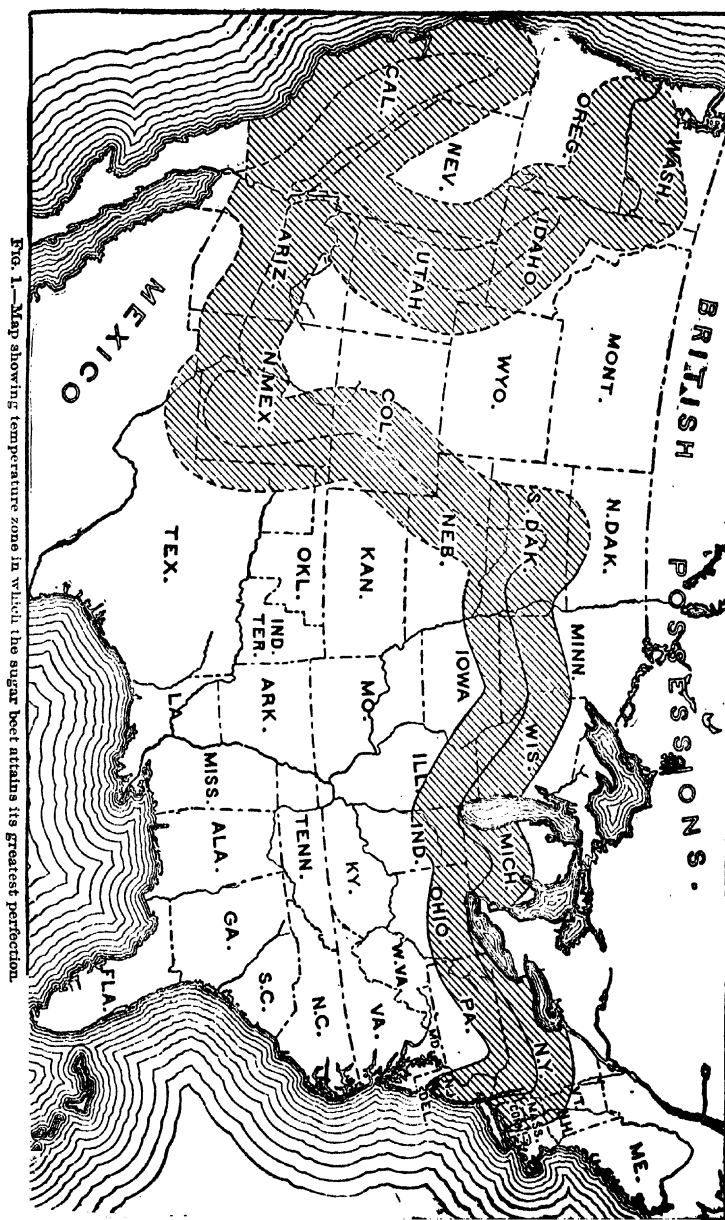

FIG. 1.—Map showing temperature zone in which the sugar beet attains its greatest perfection.

harvesting by reason of the early winter. The growth of the beet is all right. They can get an excellent quality of beet, but they are so limited for time that the industry has not proved so profitable as it has in our own country farther

south where the beets are not quite so good. We have got to take that into consideration. Now, this map, as I say, is a tentative showing of the southern limits of profitable culture; not that beets can not be grown south of this; they can, and often of a very good quality; and, as I say in my reports of this map, this is not dogmatic, it is only tentative. The probabilities are that very little successful beet culture will be found south of this region [indicating on map], although there are several factories now in operation in the South. In fact, some of the first that were established in Nebraska were south of this belt, and one in New Mexico just on the edge of it, and one in Utah just on the edge of it. This is due to the fact of this high plateau. I will say the temperature is the chief function or factor. Of course after you pass this point here you reach the arid regions. Where you have water to grow beets all beets grown along here are fine, but this great plateau has the low temperature of the southern plateau of the Rocky Mountains, so the temperature here is the same as it is here [indicating]. In the summer time it is no warmer there than here [indicating]. These lines are the isotherms of the temperature. The lower of these isotherm lines shows 71 degrees for June, July, and August; the middle line is 70 degrees, and the upper line is 69 degrees. In view of the facts mentioned you can grow beets as far north as you can go and get a harvest. South of this you can grow beets just as rich in tonnage, more so, perhaps, but contents of sugar begin to fall. Fine beets are grown on the mountains all through South and North Carolina, but the contour of the land is such that you can not get an area sufficient to supply a factory, because you have got to have contributory to a beet factory 10,000 acres for one factory of 500 tons daily capacity. You can not grow beets on the same land more than once in 4 years, so you have got to have enough land to make a 4-years' rotation, so that each acre will be planted in beets once in 4 years. Hence it requires 10,000 acres of good level land to supply one factory of moderate size. You can not grow beets on the hillside; you have got to have reasonably level land, and have got to have four times as much as is necessary to supply the factory for that one year. Some of the finest beets we have had were grown in Maryland and West Virginia on the crest of the Allegheny Mountains. I went up there last summer for the purpose of seeing if there was not enough land on these mountains to build factories. One place, I think, in Maryland and West Virginia I found where you could get enough good land to build a factory, and that would prove very profitable, because up there it is 3,000 feet high. Now, in California there is a remarkably fertile condition. That whole coast of California has the same temperature—the valleys—because they are all inundated by the winds of the Pacific Ocean. The result is that these isothermal lines instead of running east and west, as in other parts of the country, run north and south.

Q. (By Mr. SMYTH.) Due to the range of mountains?—A. No, due to the Pacific winds. Now, as soon as you go to the interior of California you get hot weather again, but so long as you stay on the coast or in the valleys on the coast, where the coast winds come in and keep the temperature down in the summer, you grow fine beets, wherever you can get water. That is the reason you see all these factories built right here.

Q. Where are beets most largely planted—what State?—A. The two States which are now taking the lead are California and Michigan. There are more beets grown in these two States than any other two. Michigan is peculiarly well suited for beet growth; also northern Indiana, Iowa, Wisconsin, and northern Ohio. All of central New York and portions of the New England States, where the land is rich enough and level enough, grow beets, and our data, which we have accumulated now, and which are found in these reports, bear out absolutely the fact which is represented in this map—that is, that although it was constructed on purely theoretical principles, before we made an investigation at all, and though it has been published now more than 10 years, the investigations made since then have shown that if we had waited to make this map until the present time the lines would have been practically what they are now. Of course there is very little of this area which is covered by this map—all these shaded portions are not suitable for beet culture. This whole region is arid, and most of it is hopelessly so; no possibility of irrigation. There are a few but not many localities where irrigation can be practiced. An arid region where, other things being equal, water can be obtained is the ideal one for beet culture. In the first place you have nothing but sunny days, get all the sunshine the beet can possibly assimilate. In the second place you control absolutely the water conditions; you can have plenty of water for the growing period, and when the crop is ready to harvest you can withdraw the water and have a dry season for harvest; whereas, in the humid regions like Michigan, there may come a September rain, nearly always does, in fact, after the beets are ripe, followed by warm weather, and the second

growth will take place greatly to the detriment of the sugar in the beets; the roads will become muddy and interfere with the harvest; so I say that the arid region where irrigation can be practiced is the ideal one for the beet grower, and you will see in the future, when this great industry takes the place which it ought to take in this country, and which it will take, that it will be the most profitable crop which can be grown upon irrigated lands, because the beet is a crop which you can grow on land worth \$300 an acre. It will pay fixed charges on such land, whereas you can not grow wheat or Indian corn on such land; a crop of wheat would not pay the interest on the investment. You have got to go into what we call intensive cultivation and then secure a large yield before you can afford to pay \$300 for an acre of land. That is about what irrigated lands cost; so it becomes peculiarly a crop suited to the highest-priced land. Now, our data have shown that after you go west of Iowa you reach a very treacherous region until you get to the arid region. The conditions of Nebraska and Dakota and all through that region there, take the seasons through, are favorable to beet growth, but there we have the most pronounced variation of meteorological conditions anywhere in the world, almost. Those hot winds from the west blow across the plains of Nebraska, and absolutely wither and cook the vegetation, and then in October they have sharp freezing weather, almost, with snow; so these rapid changes in the meteorological conditions are unfavorable to beet growth, and although two of the oldest factories in the country are established in Nebraska, yet if you will really get at the bottom opinions of the people who operate these factories, they will confess that if they were locating their factories now they would put them some place else, although now and then they get an excellent crop; so we have an intermediate and treacherous condition between the humid and arid regions. When you reach the humid region you have fluctuating conditions, and when you come to the arid regions you have more uniform forces. The conditions which obtain in Michigan and northern Ohio and New York are uniformly more favorable than in Nebraska. Our data have shown that in these localities the industry has taken root more favorably, and we find there the best results as a whole. We have repeatedly for a whole season received beets from these regions with an average of 15 per cent sugar with reasonable purity, and growing in regions where agricultural conditions are favorable, because all those regions are level. The contour of the soil is suitable to beet culture; the land is reasonably fertile; but the farmer who depends entirely upon the fertility of his soil for any crop for a series of years will become bankrupt. No land can be used continuously without feeding, no more than you can drive a work horse more than one day without giving him a meal. All land must be fed, and there is no crop which can be grown *ad libitum* on the native fertility of any soil whatever; so any radical system of agriculture—growing beets, cotton, or any other crop—must look to a period when the land must be fed, and the course is scientific, as a domestic animal is fed.

Q. Has it been necessary in Texas to manure the land?—A. Not yet. The time will come, however, when the crop will drop—when they must do something to feed it. I may mention, for example, the wheat-growing regions of the great Northwest. When they opened those regions they were able to grow 30 and 40 bushels to the acre; now they are getting 15 bushels on the same fields, and the result is that the land must be fed. You can not grow beets without fertilization. That is one crop, especially, which demands the most careful nutrition in the soil, and any system of beet culture which expects to go right along depending on the natural fertility of the soil will end in disaster. And there is another great point in this industry which the members of this commission ought to have brought to their attention; that is this, that the establishment of the sugar-beet industry in any locality is a blessing to all forms of agriculture of every description that are practiced there, because it demands a system of culture. It is scientific and just. I mean by this that the system of agriculture which robs a soil and makes it poorer is not just. The man who has a farm for 25 or 30 years and leaves it poorer than he found it has committed a crime against society. We do not bring him up before the courts and send him to jail, but he has committed a crime, because he has robbed the future. Now, I say that any system of agriculture which impoverishes the soil is a false one, but that is a rational system of agriculture which, by increasing the yield of the crops, increases the fertility of the soil. Now, if there is a crop that is grown which will teach the American farmer a lesson, the sugar beet is that crop, and there is no farmer in the world who needs that lesson brought home to him as the American farmer does. The population of the earth is constantly on the increase; the area which is subject to culture is practically exhausted. We can add in our own country only the arid regions now, little by little. Where is food to come from if not from scientific

agriculture? We can not spread our acres; we can not increase them; but what we can do, and what scientific agriculture will do, will be to increase their fertility. The beet-sugar industry has not been established long enough in this country to be an object lesson further than this, that wherever it has been established the value in farm land in dollars and cents has rapidly increased. That is a well-known fact; but I am sorry to say the fertility of the land has not increased in proportion to its value. Its value has increased some, because the beet is a more profitable crop than the crops heretofore grown on that soil; but the lesson that the farmers have not learned is that they must begin to improve the fertility of the soil in order to retain its richness. In Europe it is quite different. I have spent a great deal of time in north France, where the industry was established first, and I have collected statistics in reference to agricultural products in that country. Fifty years ago the yield of wheat in northern France—and that is the granary of France—was about 17 bushels to the acre. To-day the average yield of wheat on these same fields is 28 bushels to the acre. Now, there is a system of agriculture which increases the yield of the crop and at the same time enriches the soil. The soil of France, to-day, is more fertile than it was at the time of Cæsar, and will produce a larger yield, and that is largely due to the improvements made in the last 50 years. I think I can safely say that 50 years ago the crops produced on these beautiful fields of France were no greater than at the time of Cæsar, if as great. That whole matter has been accomplished by an application of scientific agriculture in the last 50 years, and the object lesson we have been gathering through the beet is in every case the same. The same is true of Germany. While the land is not so rich and the yields not so large, the increase has been proportionately as great. Now, what will happen in a country which simply plows and sows and sells? It will become a bankrupt sooner or later. That country will remain rich in agriculture which plows, sows, sells, and feeds its land, and the introduction of the beet as an agricultural crop will bring about that condition of affairs in this country, in my opinion, more than anything else possibly could. So, from the industrial point of view, it seems to me there is nothing touching on agriculture which is of more moment and worth more in actual dollars and cents to the American farmer than just such an object lesson as beet culture will bring. I know our fields are broad, and you may say it is wise to get fertilizer on them; but better far to grow a less area and get a larger yield than to spread over so much and impoverish and ruin the soil continuously; and, further than that, scientific agriculture will show the ways of conserving plant food so as to make it cheap and accessible to every farmer. That has already been largely accomplished, so that not only beets but every agricultural product will feel the effect of properly feeding the soil. Now, just one practical point in regard to this: The men who are putting their money in this industry to-day come to the Department of Agriculture to ask where to locate their factories, simply because we have collected the data and studied the subject, not from a monetary, but from a purely scientific point of view. We have no interest in lands one place more than another. Our interest is in the industry.

Now, there is a large factory going up in Colorado, and will be about ready for the use of this coming crop. That factory was located by the Department of Agriculture, simply by consulting, not only this map, but the data on which this map was brought out, and there were a great many localities in the State of Colorado that wanted this factory and were bidding for it here, there, and everywhere, but men who are going to put money into this industry say it is not so much the question of the bonus they get to-day, but the region that produces the most beets; that is where they want to put the factory. We had another illustration. Some capitalists desired to locate a factory near here, and went to Fredericksburg. They applied to the Secretary of Agriculture for information. He advised them not to do it, and gave them the reasons. He said, it is true you can grow beets there—very good beets—but I will show you in beets grown in that locality and 300 miles north, from the same seed, a difference of 4 per cent in the sugar content. You compete with a difference of 80 pounds per ton in the yield of sugar between these beets and those beets; you can not do it. If you were the only factory in the world you could make all the money and make sugar out of beets at Fredericksburg, but people farther north make 80 pounds per ton more sugar than you do at the same expense and of course can undersell you in any market in the world, and you had better keep out of it. That is where the practical part of such investigation comes in—pointing the investor to where the agricultural conditions are favorable and warning him from regions unfavorable. *

Q. (By Mr. A. L. HARRIS.) What ingredients of the soil are most conducive to beets?—A. Any soil that contains the ordinary elements of plant food, of a

powerful nature, is satisfactory for beets. It is more the physical condition of the soil than the chemical composition that you must consider in beet growth. A beet must have room to go straight down at least 16 or 18 inches in the soil. If it strikes hard pan it will be deflected and the tap root will turn out, and other tap roots will be produced and the beet will be stunted and ruined.

Q. (By Mr. SMYTH.) Does the shape have anything to do with the sugar contents?—A. Yes; and you will find conical beets, regular in shape, smooth in surface, with a single tap root, will, other things being equal, be the richest, and most convenient for handling; so the soil must be a pervious one, and for that reason a stiff clay is not good for beets unless it is very heavily limed. Of course you all understand that where you have a stiff soil, a very stiff soil, a liberal application of lime will flocculate it so as to make it pervious and easily penetrated by all roots of growing plants, but unless you have such treatment you want soil which is pervious. The soil of Michigan is very well suited to beet culture on account of its sand. It is a sandy loam that does not bake with rain as clay would, and so for that reason the beets have excellent physical conditions. Southern California is the same. It is mostly deposit soil in these valleys, which is not a clay soil and does not bake, but remains open and pervious. Stiff clay soils are excellent, but better for cereals that feed near the surface, like wheat and indian corn; but if they are used for beets they must be well subsoiled—in fact, all fields planted to beets must be subsoiled, and heavily limed; then beets will grow. I have seen very fine beets in Europe growing on very heavy clay soils, with a liberal addition of lime.

The manufacture of beet sugar is an infant industry in this country. When we consider the consumption of sugar in the United States and what is contributed by the beet, it is not a very large quantity—enough for two or three breakfasts; not much more. We use in this country 2,000,000 tons of sugar a year, and we produce less than 300,000 tons of all kinds—some years a little more and some years a little less. The Louisiana production, as you know, fluctuates very greatly—probably an average of 200,000 tons in periods of 5 years—sometimes more than that, sometimes less—and it is not probable that Louisiana will ever produce any more sugar than to-day. It is not far enough south for cane sugar, and it is entirely too far south for beet sugar. You all know the vicissitudes which the Louisiana cane crop has undergone the last few years, due mostly to freezing weather. The temperature has been down to as low as 13° above zero and that naturally killed practically all the cane in the State a year ago last winter. The last year's crop was a very small one. Louisiana is one of the best rice-producing States in the world. Rice is gaining and cane is losing. In 50 years Louisiana will be, in my opinion, the greatest rice-producing country in the world.

We need not expect any large increase in our cane-sugar production. It is more likely to begin to decrease than increase. Our production in Texas does not cut any great figure, although Texas has produced considerable cane sugar. Florida is likewise hardly to be considered as a cane-sugar country until at least the swamp lands are freed of water. In all localities, taking all this into consideration, I doubt if we have on an average over 300,000 tons of cane sugar in our extreme Southern possessions.

Q. (By Mr. CLARKE.) How frequently do they plant cane in Louisiana?—A. Practically every 2 years now.

Q. How frequently in Cuba?—A. Once in 15 years. I have been told that they frequently have fields that have been harvested for 50 years, but about once in 15 years they replant there. Now we are consuming 2,000,000 tons of sugar. Ten years from now we will consume 3,000,000 tons. Suppose we absorb our two so-called tropical possessions and bring their sugar in free? We would not by any means have any 3,000,000 tons. There would still be a shortage in our sugar supply, and it would take years to reestablish those industries in Cuba and the Philippines to anything like their former great figure. We have got to continue to import beet sugar from Europe or extend our own industry. My own opinion is that for 50 years to come we will need in this country from 500,000 to 1,500,000 tons of beet sugar annually, and we have got to buy it as we are buying it now, or have got to make it. Well, we are making some, but it is difficult to give a reliable estimate of the quantity. This census will give us the facts, because every locality where beet sugar is made will be visited by an expert who understands the business thoroughly, and as census agent he will get figures from all these companies. We have now got what they tell us, and we have no law in this country which compels a business man to tell any more than he wants to.

Q. Is sugar largely used in the preservation of our fruits?—A. Yes; very largely. That use is one of the chief items in the consumption of sugar in England, and

sugar is used much more extensively there than here in preserving jams, marmalades, etc.

Q. If our business of preserving fruits, jams, and marmalades was largely increased, it would call for a larger consumption of sugar?—A. Very much larger. I will say that at the present time the consumption of sugar is the greatest in England, but the consumption on the table per head is far greater in this country than in England. A great deal of the sugar that is consumed in England is used for preserving purposes and the preserved products are largely exported; it is not so generally used by the people.

Q. (By Mr. SMYTH.) In the raw state?—A. On the table and for culinary purposes. They use it for preserving, and things of that kind. We are using between 62 and 65 pounds of sugar per head in this country; in England they are using between 72 and 75; some say as high as 80, but it is a little more than it is here.

Q. Is beet sugar better adapted to preserving than cane sugar?—A. No; not so well. I think the great use for cane sugar in the future will be in that industry, while on the table for sweetening coffee and ordinary table use beet sugar will be largely employed. Beet sugar must be absolutely pure before it can be used. Cane sugar, to my taste, is a good deal better in its raw state before it is refined. I do not know of any sugar so good as the old-fashioned yellow Louisiana sugar, while beet sugar in that condition you could not eat at all, it would be so bitter. There is absolutely no difference chemically between cane and beet sugar, and they are identical in every way, but I can tell beet sugar always from cane sugar.

Q. (By Mr. CLARKE.) After it is refined?—A. Yes.

Q. How?—A. I put it in a bottle and set it away for a week, then open the bottle and smell of it, and I never saw beet sugar yet that I could not tell by its unpleasant odor. You dissolve it and sweeten with it and you can not tell any difference at all. Cane sugar, on the contrary, has a delightful aromatic odor. If you go into a beet-sugar factory, you will think you are in a soap factory, and it is a soap factory, because beet sugar contains an immense amount of potash and contains also some fat, and the odor that comes from it is a bad one and is peculiar to the manufacture of soap. You go into a cane-sugar factory and you think you are in a garden of roses, so sweet is the aroma, and so, for preserving and things of that kind, I think that the cane sugar is to be preferred for sweetening. I defy any man, woman, or child to distinguish any difference in the two pure sugars in sweetened coffee or sweetened cake. In no way is the taste different between refined beet sugar and refined cane sugar. It is absolutely the same.

I have here a list, which I will submit, of the factories in the United States which are now either in operation, or building for operation the present year. They are given in separate lists, those already built and in operation, and those building, and also a list of those which have been proposed or talked about. Some of these will materialize, and some will not, but it will all be information which you can make use of.

(The list referred to follows, giving name and location of each factory and capacity in tons of beets per day.)

FACTORIES OPERATING IN THE UNITED STATES, WITH THEIR PRESENT CAPACITY.

	Tons.
Alameda Sugar Company, Alvarado, Cal.....	800
Spreckels Sugar Company, Watsonville, Cal., formerly Western Beet Sugar Company.....	1,000
American Beet Sugar Company, formerly Chino Valley Beet Sugar Company, Chino, Cal.....	750
Los Alamitos Sugar Company, Los Alamitos, Cal.....	700
California Beet Sugar and Refining Company, Crockett, Cal., also refines Hawaiian sugar.....	500
Oregon Sugar Company, La Grande, Oreg.....	350
Utah Sugar Company, Lehi, Utah:	
Main Factory at Lehi.....	500
Slicing station at Springville.....	350
Ogden Sugar Company, Ogden, Utah.....	500
Pecos Valley Beet Sugar Company, Eddy, N. Mex.....	200
American Beet Sugar Company, Grand Island, Nebr., formerly Oxnard Beet Sugar Company.....	350
American Beet Sugar Company, Norfolk, Nebr., formerly Norfolk Beet Sugar Company.....	850
Minnesota Sugar Company, St. Louis Park, Minn.....	400
Michigan Sugar Company, Bay City, Mich.....	850

	Tons.
First New York Beet Sugar Company, Rome, N. Y.....	200
Binghamton Beet Sugar Company, Binghamton, N. Y.....	350
Spreckels Sugar Company, Spreckels, Cal.....	3,000
American Beet Sugar Company, Oxnard, Cal., formerly Pacific Sugar Company.....	2,000
Union Sugar Company, Santa Maria, Cal.....	500
Washington State Sugar Company, Spokane, Wash.....	350
Colorado Sugar Manufacturing Company, Grand Junction, Colo.....	350
Standard Beet Sugar Company, Ames, Nebr.....	500
Illinois Sugar Company, Pekin, Ill.....	700
Bay City Sugar Company, Bay City, Mich.....	600
West Bay City Sugar Company, West Bay City, Mich.....	500
Peninsular Sugar Company, Caro, Mich.....	600
Detroit Sugar Company, Rochester, Mich.....	500
Alma Sugar Company, Alma, Mich.....	500
Kalamazoo Beet Sugar Company, Kalamazoo, Mich.....	500
Wolverine Sugar Company, Benton Harbor, Mich.....	500
Holland Sugar Company, Holland, Mich.....	350
Total capacity.....	19,100

FACTORIES BUILDING IN THE UNITED STATES.

The following factories are now building at the various places in the United States. Most of them will take part in the campaign of 1900. One or two will not be operated until 1901. These factories are being constructed by the following companies at the following places:

	Tons.
American Beet Sugar Company, Rocky Ford, Colo.....	1,000
National Beet Sugar Company, Sugar City, Colo.....	500
Continental Sugar Company, Fremont, Ohio.....	400
Empire State Sugar Company, Lyons, N. Y.....	500
Utah Sugar Company, Binghamton Junction, Utah, (auxiliary to Lehi).....	350
Marine Sugar Company, Marine City, Mich.....	350
Total capacity new factories.....	3,100

PROPOSED FACTORIES THAT WILL PROBABLY BE CONSTRUCTED.

Under this head I will call attention to beet-sugar companies already organized and which give every indication at this time of constructing their factories ready for the campaign of 1900 or 1901.

The Fort Dodge Beet Sugar Company, Fort Dodge, Iowa.—Has filed its articles of incorporation. Capital, \$450,000. O. M. Oleson, president; W. T. Chantland, secretary. Most of the acreage desired by the factory has been pledged by the farmers. It looks very probable at this time that this company will materialize as an active sugar producer in the near future.

The Storm Lake Beet Sugar Developing Company, Storm Lake, Iowa.—Has recently closed contracts for total amount of acreage necessary for starting a factory at that place to participate in the campaign of 1901. It is claimed the factory is assured, provided sufficient contracts can be secured to grow beets. These contracts are now all signed, and I suppose that Storm Lake will be the first to start in the beet-sugar industry in Iowa.

The Farmers' Cooperative Beet Sugar Company, Dundee, Mich.—Have decided to build a factory this year and will begin early in the fall so as to have the plant completed by July 1, 1901. They wish to build a factory of 750 tons daily capacity.

Virginia Beet Sugar Company, Fredericksburg, Va.—This company has perfected plans for building a factory at the above place, either to commence work in the campaign of 1900 or 1901, depending upon circumstances. This project at this time seems quite probable.

The Northwest Beet Sugar Company, North Judson, Ind.—It appears that a company was organized to operate a beet-sugar factory at the above place under the name of the New England Beet Sugar Company. This company contracted for about 6,000 acres of beets to be grown by the farmers, and for some reason the New England Company could not perfect its plans and the Northwest Beet

Sugar Company was organized for the purpose of carrying out these contracts and for operating a sugar factory at the above place.

Q. (By Mr. CONGER.) Are there many being built this year?—A. Thirty factories in the United States have been in operation, with a maximum capacity of 19,100 tons of beets per day. The largest of those which I have told you is one at Salinas, which has a capacity of 2,000 or 3,000 tons per day. There are one or two of a capacity of 1,000 tons, but most of them range about 500. Some fall as low as 300, and these are maximum capacities, remember. That is, they rarely reach it, because it is seldom that you get a full 24 hours' uninterrupted work in complicated machinery like that in a beet-sugar factory, and there is always some delay with it of some kind; so you can count on about two-thirds of the maximum capacity as the real working capacity; therefore our factories now have a capacity in actual work of between 12,000 and 15,000 tons of beets per day, but we do not make altogether 100,000 tons of beet sugar. Even if working to the maximum capacity of those factories they would not make more than that. The probable yield last year was about 65,000 or 70,000 tons. This year, with the new factories and a favorable crop, the yield will reach pretty close to 100,000 tons. You see what a small quantity that is compared with the total consumption, 2,000,000 tons.

The beet factory employs all kinds of labor from the commonest to the most skilled, so from that point it is worthy of consideration. I am not an advocate of the employment of women and children as is done in Europe in the agriculture of the beet. I believe that we will be able to do with machinery in this country practically all that the women and children do in Europe and at less expense. There are some operations in the agriculture of the beet which the machinery can not attend to. There is one at least, and perhaps only one. All the rest, I believe, will eventually be accomplished by machinery, but the thinning of the beets to get a proper stand in the row must be done by an intelligent hand. You will remember what I told you about beets growing sometimes with three or four sprouts from a single seed. Now, you must leave one sprout only in the ground. If you take hold of that tuft to take it out, you will pull the beet out, hence you have got to take it between the thumb and finger and hold carefully while you detach the others. No machinery can do that, so there is one agricultural operation, thinning of the beets, that must always be done by hand, I believe. But the cultivation and harvesting, and even topping of the beets, to cut off the leaves and a portion of the upper part which contains the largest part of the injurious salts—I have spoken of potash salts—I believe all can be accomplished by machinery. Hand work is universal in Europe, and you rarely see a machine in a big field hoeing and cultivating, the work being done almost entirely by hand labor. In this country it is just the opposite. The expensive part of the agriculture, however, will be the thinning, and that we must count upon having done by hand. In addition to the field work you have the skilled laborer of the factory, which is usually the field hand in Europe, who becomes the factory hand doing day labor during the summer and skilled labor during the manufacturing season. In this way they avoid repetition of hands and give employment practically the year around, because manufacturing operations begin in the autumn in November, and there are only the probable months of January and February and part of December that there are no agricultural operations going on. During those months the factories are in operation, either working up original crops or elaborating the molasses, so the beet industry will give employment to a large number of people practically the entire year. Thus the migratory condition of labor which attaches so often to agricultural operations, as in cereal and wheat harvests, is avoided. This gives a stability to labor which is very desirable. It gives an individual interest to the labor on the farm and in the factory. In this way a better morale is established among the laborers, a more efficient corps of labor is secured, and the industry tends to advance socially and economically.

Q. (By Mr. A. L. HARRIS.) Have you a total of the amount of labor required to supply this country's need in sugar?—A. Well, you can base it on the factory say of 500 tons capacity, which will require 4,000 acres of beets under cultivation and 8,000 in other crops in rotation—12,000 acres. It will require a corps of about 120 efficient laborers the year round to conduct that business—I mean laboring men, not women and children—and if the average family is 3 or 4 persons, that is probably 400 or 500; so a beet-sugar factory supports during the entire year a laboring population approximately equal to the number of tons of its daily capacity. Four or five hundred factories of 500 tons each would supply our present needs, and in that way you can compute the number of laboring men which this business will employ. This does not include the men who make the machinery, build the factories, and repair them. That touches other branches of industry—manufacturing industry. What I have given you is actual labor

on the farm and in the factory; and this labor, as I told you, in Europe is the very best. It is an educating business. The people there of other manufacturing want to get men who have worked in the beet factories; want to get them for labor. I had a conversation a short time ago with a German who is one of the largest manufacturers in Europe. I said, "You must be oppressed by this military law which requires every man to do 3 years' service?" He replied, "On the contrary, it is the salvation of the country. It takes the young men who do not know anything and makes men of them; teaches them to be men, makes them stand straight, makes them agile and quick, and the men who go through the military service are the men we want in our factory." In that way the tendency is to build up an educated corps of laborers through the military service.

Q. (By Mr. SMYTH.) This is particularly the case of Germany?—A. Germany; I am speaking of Germany. Their military service is universal education. It is not a hardship and a curse. I had considered it a curse to the country, but after he told me, and after I investigated the matter further, I believe it is a good thing.

Q. How many tons of foreign beet sugar were imported to this country last year?—A. I have not the statistics for the last year. Year before last it was 800,000 tons.

Q. What is the duty paid on that?—A. It amounts to about 1.8 cents a pound; that is what usually comes in—about 1.8 cents a pound.

Q. What was the production of the United States for the same year of beet sugar?—A. That year about 50,000 or 60,000 tons.

Q. But the industry is growing?—A. Growing, and growing in a healthy way. It is not increasing rapidly, but has a healthy growth, which is much better.

Q. But it is absolutely necessary to import that quantity of sugar to the United States, or it would be short in its supply, would it not?—A. Can not get it anywhere else. There is no question that we needed it, and we bought it. Of course, beet sugar comes to us when we do not get the cane sugar. Our natural sugar supply from the islands was exhausted. We used to get a million tons from Cuba, and after the rebellion broke out there and until the Spanish war began, we got less than 200,000 tons from Cuba. Now, it is growing a little, but if everything was established to-day in a most prosperous way, it would be 5 or 6 years before they could get up.

Q. Don't you expect them to get back?—A. Yes; eventually they will get ahead. In the meanwhile we are eating more sugar and using more.

Q. You think, then, the increase of sugar product from Cuba will be a detriment to the German sugar?—A. Yes; as Cuban comes in, German will stay out.

Q. The duty is the same on cane as beet?—A. On the beet sugar we have a countervailing duty; that is, countries which give a bounty to export, we increase the duty to them under the present law, and as Germany gives a bounty for export, it pays us a slightly higher rate; then we learn, by as careful investigation as we can, the amount of the export bounty, and add that to the duty.

Q. (By Mr. KENNEDY.) Have you given any thought to the possibilities of the production of sugar on the island of Cuba with respect to the world's consumption?—A. I have looked into that matter quite carefully. Cuba is the natural sugar-producing country of the world. There is no other country that can compare with it. Now, I have never been in Cuba myself; I have only formed my ideas from conversation with Cubans and with people who have been there, and from reading accounts; but my impression is, based upon all the information I can collect, that Cuba has a capacity, or will have a capacity, of producing from 3,000,000 to 4,000,000 tons of sugar as a maximum per year, but to do that those immense forests have to be subjugated, railroads have to be built, marshes have to be drained, which is going to be a slow process. I will make this prophecy: If Cuba is prosperous and has a stable government, in 50 years she will produce 3,000,000 tons of sugar per year.

Q. (By Mr. CONGER.) What has been the maximum production there in the past?—A. About 1,000,000 tons, rarely gone beyond it; but in 50 years the United States will eat 6,000,000 tons of sugar, or more, so we will have the same relation to consumption and supply that we have to-day, and the same necessity for domestic industry that we have to-day. That is allowing the most favorable extension and development of the tropical regions. There is one peculiar fact concerning tropical cane: It is not susceptible to scientific improvement as the beet is. The sugar cane to-day is what nature made it, and you can not make it anything else; it has been tried ineffectually. You can improve it a little by selection. You know, in planting the cane—

Q. (By Mr. SMYTH.) Plant the joints?—A. Plant the joints. It is produced to a limited extent from seeds, to a very limited extent. It has only been done for a few years. I can remember when it was boldly asserted by botanists that cane

could not be produced from seeds, but to-day we have growing in different parts of the world some very fine varieties of sugar cane produced from the seed, and constantly producing others, but I have never heard of them for commercial purposes. When they produce cane from the seed they plant that cane just the same as old cane. Therefore, the possibilities of improvement in the manner that the beet has been improved are limited. Now, the British are good farmers, better than the Spanish, and they have possessions in the West Indies, but they never have been able, with all their skill, to compete with Cuba in producing cane sugar, and to-day the sugar industry in the British West Indies is bankrupt. You have doubtless seen the West India Commission's report. The commissioners came through here, and I had several interviews with them in regard to the industry down there. They made a thorough investigation, and the result is that the home government has given several hundred thousand pounds to keep the industry from becoming exterminated. In other words, science with the sugar beet, if necessary, can destroy the natural sugar plant in the Tropics. For instance, in the sugar-beet industry it is not the production of sugar alone that you secure. You build up around a factory a vast dairy industry. You have your pulps and other refuse and leaves to feed to the cattle, and it makes fine butter and milk. You can not do that with the refuse of sugar cane. Cattle can not live in the Tropics; you can not establish a dairy there, and it is sugar and nothing else, and you all know the great strength of the agricultural industry—that it is varied, not confined to a single idea. You know that [speaking to Mr. Smyth]. You are in a cotton country. You know if you have cotton alone that you have a hard struggle. You have got to diversify agricultural industries even in the South. A single agricultural industry does not stand well alone anywhere in the world. It is the universal history of the world that you have got to have a prop and support to it. Now, beet sugar is a support. It is held by all other allied industries that it has a better show in the fight than even the cane in the Tropics. Now, I have said that Cuba is the garden of the cane; the same is true of the Hawaiian Islands, but there nature has prevented any great expansion. Practically all the land in the Hawaiian Islands capable of growing sugar is under cultivation. It does beat Cuba, I will admit, acre for acre. It is most conveniently placed. A yield of 14 tons of sugar, not of cane, has been obtained in the Hawaiian Islands, 14 tons to an acre of land, something almost incredible; but the British, with all their agricultural skill, with their fertile soils—Barbados and British Guiana—their sugar industry has gone to the wall in competition with the beets of Europe. Now, capital can stand up in the Hawaiian Islands, for a time at least, but it may be in the future these countries will reach their limit and feel the effect of this competition. Now, we want to be in it in this country. We have a marvelous climate, with great possibilities of development. So I say from an industrial point of view the development of the sugar industry in this country is worthy of your consideration as investigators of these great industrial problems.

Q. (By Mr. CONGER.) How about the Philippine Islands as a place for the sugar industry?—A. I know less about them than Cuba.

Q. Is it your idea that those engaged in this beet-sugar industry need have no fear of the effect of their being included?—A. Absolutely none. When the Spanish war commenced and my friends commenced to write to me these despairing letters that we were going to be ruined by free sugar, I never for a moment had any fear. If we to-day were to admit absolutely free from duty every pound of sugar made in Porto Rico and Cuba and the Philippines, it would not affect the progress of our sugar-beet industry in this country. We still have to have this deficit in sugar supplied from some place, and the best place to get it is here, right in our own country.

Q. If this cane sugar from Cuba would be admitted free, would not the price of sugar be less here, necessitating the factories running at a less profit and possibly at a loss?—A. Suppose we admit free of duty this sugar. We would still have to import sugar, and the duties on sugar would probably remain the same as they are. That would tend to fix the price of sugar. By the way, it is not an unmixed evil to have a low price on an agricultural crop; it has a good many good points. In the first place, it increases consumption and the demand for the article, and that tends to restore the price. In the second place, it teaches economy in the manufacture which otherwise would never have been taught. Louisiana people, if you had told them two or three years ago that they would have to sell their sugar at 2½ cents a pound, they would have held up their hands in horror; but they are doing it and making money.

Q. (By Mr. CLARKE.) Not under their old methods?—A. No; they had to change their agriculture and manufacture and it has been to their benefit. They are in a better position now than when they got twice the price for their product.

Q. (By Mr. CONGER.) Is it not true that the great production in Germany has been secured only by bounties being paid?—A. That is true, but it has never been paid to the grower. There is a great deal of misapprehension or misunderstanding in that respect in this country. The bounty is paid to the man who exports the sugar. The grower and manufacturer, unless an exporter, get nothing.

Q. Does he not get it indirectly?—A. He may indirectly, but the man who grows the sugar has to pay a heavy tax. The German Government collects more in the tax on its beets than it has ever paid in bounty.

Q. Do you mean the industry is taxed more than other forms of agriculture?—A. The average tax on every ton of beets grown in Germany was until recently nearly \$4, revenue tax. A corresponding tax is now levied on sugar consumed within the Empire. Every factory is run like a distillery. A Government officer stands at the scale and keeps the data of all exported sugar.

Q. Can you say what sugar can be manufactured for in Germany exclusive of the tax?—A. I should say 2½ to 2¾ cents a pound.

Q. I judged from what you have said, it is your idea it can be produced as cheaply here?—A. As I said, perhaps a little bit more—perhaps 3 cents a pound under the best possible conditions which should obtain—that is, of manufacture, location, etc. The actual cost in this country has probably been more than that up to this time, because a great many unfavorable conditions have obtained.

Q. (By Mr. SMYTH.) One of which was, I suppose, the business being new and having to be learned by experience?—A. Yes; that has been the most important one, especially on the part of the farmer.

Q. (By Mr. A. L. HARRIS.) Does the sugar as it comes from the American factory require refining?—A. All the beet-sugar factories in this country, with one or two exceptions, make a refined sugar directly, so they do not have to go to the refiners at all. They are totally independent of the sugar trust. That is a great advantage, too, because they can sell the sugar to the trade. There are one or two controlled by Mr. Spreckels that make raw sugar and send it to his refinery in San Francisco, but all the other factories, so far as I know, make a refined sugar and sell directly to the trade.

I have referred so often to the German beet-sugar industry that it seems advisable to insert in the testimony a brief statistical statement showing the progress of that industry in the German Empire during the past sixty years.

The following tables abridged from a supplement of the March, 1900, number of the *Zeitschrift des Vereins für die Rubenzucker-Industrie des Deutschen Reichs*, exhibit in a striking manner the growth of the beet-sugar industry in Germany during the past sixty years.

The improvement in the quality of the beets grown and the manufacturing processes is also apparent from Table No. 1, in which it is shown that the beets yielded but 5.88 per cent of sugar in 1840-41, while in the campaign of 1898-99 the yield was 13.37 per cent of the weight of the beets.

The development, during the last three decades, of processes of recovering sugar formerly lost in the molasses has contributed considerably to this increased yield. Statistics relative to the utilization of molasses in Germany are given in Table No. 2.

During this period of sixty years the sugar production has increased from 142,056 to 16,270,720 hundred-kilogram units (from 15,659 to 1,793,539 tons of 2,000 pounds), while the importations of sugar have decreased to the very nominal amount of 1,236 tons.

At the same time the Empire's export trade in sugar has increased until now more than one-half the entire product of her factories is sent abroad. The application of scientific methods in the field and in the factory has greatly assisted in attaining this result, but it has only been possible with the aid of most favorable revenue and tariff laws, the nature and working of which are set forth in Table No. 3. A very high tax on imported sugar has been maintained since 1840, with a differential in favor of the German refiners until 1887. An export bounty also, with a differential in favor of German refiners, has stimulated production for export. From 1841 to 1892 an internal-revenue tax was levied on beets used for sugar production. Since 1889 this has been replaced by a corresponding tax on sugar consumed within the Empire. The export bounty was reduced at the same time the manufacturers were relieved of the tax on their raw material.

Among the important effects of this system of sugar laws, there must be mentioned besides the stimulation of production, the depression of domestic consumption of sugar, and the embarrassment of the refiners of sugar in England and of the raw-sugar producers in colonies of that country. Moreover, the system has yielded the Government a net revenue varying from 0.31 to 1.99 marks per capita per year.

TABLE NO. 1.—Statistics relating to the number of beet-sugar factories in the German Empire, the yield and working of the beets, and the wholesale price of sugar in the manufacturing years 1839-40 to 1898-99.

Year.	Number of factories in operation.	Quantity of beets worked.	Yield of beets per hectare. ¹	Average price paid for beets.	Average quantity of beets worked per factory.	Quantity of raw sugar obtained (all products).	Yield per 100 kg. of beets.		Quantity of beets necessary to produce 100 kg. of raw sugar.	Price of sugar per 100 kg.	
							Raw sugar (all products).	Molasses.		Raw sugar.	Refined sugar.
		100 kg. ¹	100 kg.	Mks. per 100 kg. ²	100 kg. ¹	100 kg. ¹	Kg. ⁴	Kg. ⁴	100 kg. ¹	Marks. ³	Marks. ³
1840-41.	145	2,414,867	16,654	142,056	5.88	3.70	17.00
1845-46.	96	2,227,546	23,263	151,534	6.80	3.10	14.70
1850-51.	184	7,362,155	40,011	533,489	7.25	2.70	13.80
1855-56.	216	10,019,900	50,555	873,502	8.00	2.35	12.50	87.00	126.00

1870-71.	304	30,506,456	100,350	2,629,867	8.62	2.60	11.60	68.00	111.00
1875-76.	332	41,612,842	122,328	3,580,482	8.60	3.22	11.62	54.50	85.50
1880-81.	353	63,222,030	160-2.70	190,696	8.70	2.61	11.37	62.00	81.00
1885-86.	369	70,703,169	1.40-1.80	177,200	8.061,049	11.49	2.55	8.75	60.70
1890-91.	406	106,253,194	1.60-2.50	261,657	12,844,853	12.16	2.50	8.27	55.00
1891-92.	403	94,880,022	1.80-2.30	235,434	11,443,676	12.16	8.26	59.50
1892-93.	401	96,119,367	2.10	244,686	11,718,430	11.94	8.37	55.00
1893-94.	405	108,443,515	2.12	262,823	13,166,046	12.34	8.10	53.00
1894-95.	405	145,270,295	2.02	358,543	17,068,151	12.15	8.23	41.50
1895-96.	397	116,728,164	1.77	294,025	15,375,220	13.11	7.63	46.00
1896-97.	399	137,209,295	1.77	343,000	17,388,846	12.16	7.90	46.50
1897-98.	412	136,978,920	1.73	340,743	17,552,290	12.79	7.80	46.50
1898-99.	402	121,506,422	1.83	302,255	16,270,720	13.37	7.48	47.50
1899-1900.	124,626,769	20.25	47.00

¹100 kilograms (= kg.) are equal to 220.46 avoirdupois pounds. Therefore, if the number expressing the quantities stated in this table in units of 100 kg. be divided by 10, the result will be in terms of the metric ton of 1,000 kg., which is approximately equal to 1 long ton (2,240 pounds).

²100 kilograms per hectare is equivalent to 220.46 avoirdupois pounds for 2.471 acres; or, roughly estimated, is equivalent to 100 pounds per acre. For example, the yield for 1898-99 is stated to be 285 100-kg. units per hectare. This is roughly equivalent to 285 hundred pounds or 14.25 tons per acre. The accurately calculated equivalent is 12.7 tons per acre. This more accurate equivalent is obtained by multiplying the number of 100-kg. units by 0.0446, i. e., 100 kg. per hectare \times 0.0446 = tons per acre.

³The German mark is equivalent to 23.8 cents. One mark for 100 kg. is therefore equivalent to 0.0108 cents per pound, or to \$2.16 per ton (2,000 pounds). One mark is equivalent to 100 pfennigs.

⁴One kilogram (= kg.) is equivalent to 2.2046 pounds. The quantities given in this column are equivalent to percentage of the weight of the beets.

TABLE No. 2.—Statistics of the production, importation, utilization, and export of molasses for Germany during the twenty-nine manufacturing years 1871-72 to 1898-99.

Year.	Molasses made in sugar factories.	Molasses imported.	Quantity of molasses used for extraction of sugar. ¹				
			Osmosis process.	Elution and precipitation process.	Lime saccharate separation process.	Other processes.	Strontium saccharate process.
	100 kg. ²	100 kg. ²	100 kg. ²	100 kg. ²	100 kg. ²	100 kg. ²	100 kg. ²
1871-72	638,917	154,639

¹ The process of reboiling and recrystallizing purified beet juice leaves a by-product, called molasses, which still contains approximately 50 per cent of sugar, but from which practically no sugar can be separated by crystallization. The above table includes statistics for five of the more important processes that are used for the recovery of sugar from molasses in Germany.

In the *osmosis process* the molasses is circulated on one side of parchmentized paper, while water is circulated on the other side. The salts, which prevent the crystallization of the sugar in the molasses, diffuse through the paper much more rapidly than the sugar. By this means the molasses is sufficiently purified to permit the extraction of more sugar by reboiling and crystallization. This process, as the table clearly shows, has largely been displaced by later inventions.

The *elution process* depends on a formation of a compound of sugar and lime known as calcium, or lime saccharate. This compound is treated with alcohol, in which it is insoluble. The alcohol washes out the impurities of the molasses, leaving the saccharate in a comparatively pure state. The purified saccharate is then suspended in water or in beet juice and treated with carbonic acid gas, by which it is decomposed, uncombined sugar and insoluble carbonate of lime being formed. The mixture is then passed through a filter press which retains the carbonate of lime. The clear filtrate is then evaporated for the crystallization of the sugar, which is dissolved therein. This process is likewise falling into disuse.

In the *lime saccharate separation process* saccharate of lime is formed from which the impurities of the molasses are separated by washing with water. The purified saccharate is decomposed with carbonic acid gas, and the recovery of the sugar completed as in the preceding process.

The *strontium saccharate process* is similar to the one last described, with the exception that strontium hydrate is used for the formation of the saccharate in place of lime. This process has largely replaced other processes in Germany.

² 100 kilograms (= kg.) are equivalent to 220.46 avoirdupois pounds. Therefore, if the numbers expressing the quantities stated in this table in units of 100 kg. be divided by 10, the result will be in terms of the metric ton of 1,000 kg., which is approximately equal to one long ton (2,240 pounds).

³ The German mark (100 pfennigs) is equivalent to 23.8 cents. One mark per 100 kg. is, therefore, equivalent to 0.108 cent per pound, or to \$2.16 per ton (2,000 pounds).

TABLE NO. 3.—Statistics relative to the sugar laws, inland and import bounties on sugar, gross and net revenues received by Government from these sources, quantities of sugar imported and exported, and annual consumption of sugar per capita in Germany from 1840 to 1899.

Calendar year—	References to laws.	Bounty on exported sugar of domestic production.				Import tax.				Imports.				
		Internal-revenue tax on sugar of domestic production consumed within the Empire (marks per 100 kg.). ¹	Internal-revenue tax on beets (marks per 100 kg.). ¹	Raw sugars of at least 90° polarization and refined (marks per 100 kg.). ¹	Block candy and other sugars polarizing at least 90° (marks per 100 kg.). ¹	All other sugars polarizing at least 90° (marks per 100 kg.). ¹	Raw sugars (marks per 100 kg.). ¹	Crushed loaf and white powdered sugar (marks per 100 kg.). ¹	Refined sugar (marks per 100 kg.). ¹	Strap and dutiable molasses (marks per 100 kg.). ¹	Reined sugar.	Raw sugar.	Strap and dutiable molasses.

¹ The German mark is equivalent to 23.8 cents. One hundred kilograms (= kg.) are equivalent to 220.46 pounds avoirdupois. One mark per 100 kg. is therefore equivalent to 0.108 cents per pound, or to \$2.16 per ton (2,000 pounds).

² Export bounty on raw sugar exported in the form of refined sugar.

³ In addition to this the German sugar producers pay a manufacturers' tax which varies with the amount annually produced by each factory as follows: Manufacturers making 4,000,000 kilograms or less, pay a tax of 0.10 mark per 100 kilograms; those making 4,000,000 to 5,000,000 kilograms pay a tax of 0.125 mark per 100 kilograms; those making 5,000,000 to 6,000,000 pay a tax of 0.15 mark per 100 kilograms, etc., the tax per 100 kilograms increasing by 0.025 mark for each 1,000,000 of annual production.

TABLE No. 8.—Statistics relative to the sugar laws, inland and import taxes and export bounties on sugar, gross and net revenues received by Government from these sources, quantities of sugar imported and exported, and annual consumption of sugar per capita in Germany from 1840 to 1899—Continued.

Calendar year:	References to laws.	Exported sugars subject to export bounty or rebate.			Total revenues yielded the German Government by sugar taxes.						Annual consumption of sugar per capita in Germany.
		Haw sugars.	Block candy, etc.	Other hard sugars.	Tax on sugar and raw material consumed within the Empire.	Tax on imports.	Sum of inland and import taxes.	Export bounty.	Net yield of revenue.	Per capita based on the population for the year for which each amount is given.

¹ The German mark is equivalent to 23.8 cents. One hundred kilograms (= kg.) are equivalent to 220.46 pounds avoirdupois. One mark per 100 kg. is therefore equivalent to 108 cents per pound, or to \$2.16 per ton (2,000 pounds).
The German mark (= M.) is equivalent to 2.2046 avoirdupois pounds.

¹ The German mark is equivalent to 23.8 cents. One hundred knoggrams of wheat cost 43.0108 cents per pound, or to 32.16 per ton (2,000 pounds).

One kilogram (= kg.) is equivalent to 2.2046 avoirdupois pounds.

(At a subsequent meeting of the commission, May 15, 1900, during the examination of Prof. Robert C. Kedzie on the same subject, Dr. Wiley was recalled, and, pursuant to a motion of Mr. Clarke, was interrogated by Dr. Kedzie touching certain features of the latter's testimony, and answered as follows:)

Q. (By Professor KEDZIE.) I desire Dr. Wiley to state the results of their constant investigations in regard to the question of the deductions to be made from the total amount of sugar found in the beets, and to explain how he arrives at what is commonly known, technically known, as marc, and the importance of this as related to the sugar-beet industry as between the farmer and the factor.

Dr. WILEY. The usual commercial method of determining the amount of sugar in a beet is an indirect one. We proceed for the purpose of convenience and speed by expressing the juice from the beet, and determining the amount of sugar in that expressed juice, and then from that calculating back to the per cent of the beet. Now, it may seem strange to you that a body as firm as a beet is almost all liquid. What is not liquid is solid in solution. In other words, a body which seems so firm is 95 per cent liquid, or solid in solution, and only 5 per cent of the whole mass is really solid matter, insoluble. That insoluble matter in technical language is called marc, a French word which came into use with the French method of analysis. We call it fiber or pith. Now, in order to determine the amount of sugar in the beet, the amount of marc must be known, otherwise we would not be able to compute from the percentage of sugar of the juice the relation which that percentage bore to the original beet before the juice was expressed. Now, you can easily see, if 95 per cent of the whole weight be liquid or solid in solution, that only 5 per cent insoluble matter would remain; therefore the percentage of sugar measured in the juice would have to be multiplied by a factor, point 95, to determine the amount which would be in the original beet. For example, suppose you have a juice which polarizes 14 per cent. This measures the amount of sugar in that juice, but the juice represents only 95 per cent of the whole weight; therefore you have to use that factor to reduce it to the original weight. The beet would not contain as much sugar itself as the juice would, because the beet weighs more than the juice, and you have to divide the total amount of sugar by the whole weight. Now, beets are sold by the percentage of sugar which they contain. It is important to the farmer, as well as to the manufacturer, that a fair method of computation be agreed upon. The usual custom has been to use the factor point 95, assuming the beet contained 5 per cent of insoluble matter, and thus the farmer and the manufacturer have been satisfied. That has been the rule which has been in vogue mostly in this country. It is a rule we have had in our own investigations at the Department, and I think it is a fair one, but of course there are variations in the amount of marc which the beet may contain—if it is grown at an exceptionally dry time, if it is exceptionally ripe, if it contains a second growth, or if it suffers any accident that would change it from its normal condition. In the too ripe beet the tendency is to increase the percentage of marc and decrease the soluble matters; as, for instance, if the mother beet grows and produces its seed, almost everything left is insoluble; the juice is all gone. That is an extreme case.

Q. (By Mr. CONGER.) I would like to inquire if in making this showing of marc it would vary according to the efficiency of the machine for pressing out the juice.—A. No; not at all. We do not express all the juice; don't attempt to. We have no machine that will do that. In making an analysis we only express a portion of the juice, but experience has shown that the juice which remains has practically the same composition as that which is expressed. An ordinary press will not take out more than 50 or 60 per cent which the beet contains. That is the reason the press can not be used in commercial operations as in the case of sugar cane. A good strong sugar mill properly adjusted will take out from 80 to 83 per cent of the juice which the cane contains, but you could not express by any kind of press that much juice out of the beet.

Q. (By Professor KEDZIE.) Supposing a factory assumes a factor of 88 instead of 95, what have you to say in regard to that?—A. Well, it would be a case where a load of beets would have 12 per cent marc; good for the companies, but an injustice for the farmer.

Q. Established for the whole?—A. To establish a factor so abnormal and apply it to a normal beet is unscientific and unjust. The principal thing is to establish a factor for a normal beet, and then if there are abnormalities they must suffer one way or the other, because you can not have a different standard. You must apply what would be a fair standard to a normal condition of affairs. Now, it is stated by the advocates of higher marc that in extracting sugar in alcohol it is found that the marc sometimes corresponds to a marc of 8, 10, or 12 per cent. That is not a fair statement of the question. Alcohol dissolves sugar with great

difficulty, and the stronger the alcohol is the more difficulty there is in dissolving the sugar, and it is the common experience of the chemist that if you use alcohol for extraction you can, if you continue the operation long enough, extract all sugar, but in the ordinary time, when such extractions should continue half an hour to 2 hours, quite a considerable percentage of the sugar will not be extracted. There is a method, however, that has come into use in France in the last few years and which seems perfectly fair and can apply to all, because by this method they determine the percentage of sugar in the pulp of the beet without expressing the juice by means of what is called aqueous diffusion, not using alcohol, but using water. The truth of this depends on the fact that by using a peculiar form of rasp you can obtain from the beet an impalpable pulp; that is, a pulp in which the beet cells containing sugar have been ruptured. Then when you mix that with water the sugar content passes into solution, and you polarize it directly after adding clarifying agents and filtering, giving a perfectly clear solution. Such a method as this would give a correct percentage of sugar in every case. That method has in the last 10 years come into very general use commercially in France, and if the friction continues in this country between the factory and farmer I would strongly advise the introduction of the method here. That would give a result that nobody could question.

Q. (By Mr. CLARKE.) How would that work, practical?—A. It is almost as rapid as the ordinary method of expressing the juice. We have not used it in this country, because the uniform custom has been to use the other method. We have used it in our laboratory to determine the absolute factor 95, which we find on the average is a correct one, but in certain abnormally favored conditions such as exist in California, and such as existed last year in Michigan, it might be well, in the interest of harmony, for all parties to adopt this method. All the accounts for Michigan last year show they had abnormal conditions there, and probably the marc was in many cases more than 5 per cent; it may have amounted to 8 per cent. That is hardly likely even in abnormal conditions, unless they have a second growth, and so the factories may in some instances have had a just ground for increasing the quantity of the marc for these reasons; but it would be very unfair to apply them this year, perhaps, where beets are perfectly normal. Now, this all goes to show that the actual percentage of marc for the normal beet is a little less than 5 per cent, so taking this 5 per cent we make some concession to the manufacturer after all, and the farmer is in favor of letting it go at that, but I certainly would protest in the interest of the farmer against a factor as high as 8 per cent; even 6 per cent would be, in my opinion, a little bit too high. Of course it is only a small increase, and I believe I said finally of Michigan, where the manufacturers were contending for a factor of 7 per cent and Dr. Kedzie and his people for one of 5 per cent, that I would be willing to make a compromise and accept 6 per cent to settle the difficulty, so that each one would receive a little concession. But to make it 14 per cent is certainly—the language which is attributed to me here would not be too strong, to characterize that as robbery, because such a condition would never occur except in very exceptional instances in a few beets; but never in a field of beets that have grown even under abnormal conditions.

Another point which Dr. Kedzie asked me to say something about is in regard to the removal of the friction between the farmer and the manufacturer, by cooperation. Of course the interests of the manufacturer and farmer are identical. What is good for one is good for the other. If a manufacturer wishes to in any way get the advantage of the farmer he is cutting his own throat, and the farmer who wants to get the best of the manufacturer is defeating his own interests. Success is a mutual benefit to both. That is where higher success lies, but suppose they can't see that. These things will all adjust themselves in the course of time, however, and they have adjusted themselves in Germany largely through cooperation. Practically about one-half of the beets grown in Germany belong to the farmers who have shares in the factories.

The most complete data which I have before me on the subject relate to the "campaign" year 1894-95, and they were collated and published in 1896. The area under cultivation for the year covered by the data was 1,090,801 acres, or 441,441 hectares. The yield of beets was 32.9 tons per hectare, or 13.3 tons per acre. Of the above crop, 41.64 per cent were grown by the factories and 58.36 per cent were bought by the factories. This percentage varies slightly from year to year, but represents upon the whole very closely the relative magnitude of the cooperative beet growth as compared with the total magnitude of the industry in Germany.

It is evident that if such a system of cooperation could be established in our own country it would be very much more satisfactory to the farmers and to the factories as well, inasmuch as the former would be factory owners.

I believe that is the best solution of this whole difficulty. It is a little hard on people who are not in the cooperation—farmers, for instance—because there is a mutual understanding in the cooperative factories that the price paid for beets shall be very low, so that those who are not in the cooperation get squeezed while those who are in get the benefit. For this reason the statistics for the price of beets in cooperative factories in Germany are unreliable, because all the cooperative factories pay less for beets than the noncooperative factories; but still cooperation makes a perfect unity of feeling between the grower and manufacturer, because they are practically the same person. I believe in the course of time the cooperative factory will be a very large element in this industry in this country. However, as Dr. Kedzie says, these difficulties will adjust themselves. Last autumn the farmers of Michigan were up in arms and swore they would not grow any more beets, but now they are planting, as you see, and getting almost their full complement and full acreage. The farmers, I think, should have the first concession, because it is to the farmer that the first success must be looked for. Without successful agriculture nothing else is possible. The best appointed factory, best managed factory, with no beets will make no sugar, while the poor factory with plenty of beets will make lots of sugar; so first of all the agriculture must be set upon its feet in this industry. The wise manufacturer will concede to the farmer a little more than may be just in order to help him along and secure the establishment of the industry in a proper way.

Q. (By Mr. SMYTH.) In the testimony you gave us yesterday you were telling us about the experiments, as I understood, in the Agricultural Department here, in testing the percentage of sugar in other beets; and you stated it was below 15 per cent, one class, 16 per cent another, 17 per cent another, and 18 per cent another. I want to ask for information, Does the quantity of sugar in the beet increase with the increased percentage? In other words, a beet that contains 18 per cent has a good deal more sugar than one that contains 16 per cent?—A. It has 40 pounds per ton more. Each per cent of increase in sugar amounts to 20 pounds to the ton of 2,000 pounds of beets.

Q. It is all taken to make the analysis?—A. Yes; when we speak of 16 per cent, we mean 16 pounds in the hundred.

Q. Shows an actual increase in the quantity of sugar?—A. That is 320 pounds in the ton as the actual weight of the sugar. When we state the per cent we refer to 100 pounds of raw material.

Q. That is the point, whether the percentage is based on the single beet?—A. On one-hundredweight of beets.

Q. It costs no more to raise beets containing 18 per cent than 16 per cent?—A. Just the same, exactly.

Q. The same amount of fertilizer per acre?—A. You may have to use a little more fertilizer to make a little more intensive culture.

Q. It pays the farmer, however, to try to get the largest percentage in the beets?—A. Yes, it does pay the farmer, and it certainly pays the manufacturer, because every additional percentage of sugar in the beet means a clear yield of 20 pounds more sugar per ton, because the amount of waste in the manufacture is just the same. In fact, you waste more in the lower percentage, because the character of the juice deteriorates; you get a less percentage of sugar proportionately; so to the manufacturer the high percentage of sugar is even more important than to the farmer.

Q. Now, does the farmer get that advantage of that increased value of beets when it contains a high degree of sugar?—A. Yes; he gets more for it; say 12 per cent is the basic price; each additional per cent of sugar, so much increase. That is the general form of the contract throughout this country. The farmer has a direct interest in growing beets with a high per cent of sugar. That is secured largely by using high-grade seeds and by planting very thick so as to prevent the beets from growing more than a pound in weight. In this way you will get the highest percentage of sugar.

Q. (By Mr. CONGER.) That custom in doing more for a higher grade of beets is practiced in Europe as well, is it not?—A. In most parts of Europe. In France they buy beets simply on flat prices per ton, knowing about what they will be from year to year, but wherever that has been practiced, the tendency has always been to have a low degree of beets. It is only where beets are paid for by the quantity of sugar they contain that the higher results have been secured. I will state here the average yield of beets per acre in Germany is about 18 tons, based upon a long series of years. In France it is a little over 11 tons an acre, in Austria about 10½ tons, and in Russia it is less.

Q. In this country?—A. This country nobody knows, but I imagine if you take all the fields planted to beets since the industry started, that the average yield would not be 5 tons to the acre.

Q. (By Mr. CLARKE.) What do you think it will be when beets are properly cultivated?—A. I think we will do as well as Germany. But it will be many years before we do have an average yield of that kind. I have visited hundreds of beet fields myself, and I have been surprised to see the number of poor ones. I saw thousands of acres in California last year that would not yield a ton to the acre.

Q. (By Mr. CONGER.) That was practically a failure of the crop, was it not?—A. Absolute failure, you might say. Now and then you would run across a field of 20 tons.

Q. (By Mr. SMYTH.) To what do you attribute that condition there?—A. Sometimes it is a natural condition of drought, but more often where it is not that it is carelessness in culture. Two years ago one of the land agents of a western railroad in Minnesota applied to the Department for a large quantity of seeds, which he was going to have grown along the lines of his railroad—and lands which are well suited to grow beets, too, both by location and fertility. In July of that year, at his request, I went with him on a tour of inspection to see the result. We spent a whole day hunting for beets in the grass as high as this table. We found only one plot out of fifty we visited where any attempt had been made to cultivate the beets at all. I have no doubt you can corroborate these observations in a great many localities. In that one field we found beets, splendid beets, and the others were absolutely neglected, and that has been the history of beet culture on a large scale. That is an extreme case of neglect—in the first place, ignorance. It is a pretty hard thing for even an intelligent man, if he has never seen beets grown, to prepare the soil and cultivate the beets correctly. Now, I went out the other day to plant beets on the Department beet farm—3 acres. Well, I never had set a beet drill. I did not know how to set a drill to sow 20 pounds of beet seed to the acre. I got a hard place in the road where the beets would not go in the ground, and I measured a distance—I knew the number of seeds in a pound—and I ran that drill until I got, by counting the seeds, the rate at which 20 pounds would be planted to the acre. It took me an hour to find out how to set the drill to drop these seeds. Now, suppose a farmer never made a calculation of that kind. How is he going to get the right amount of seeds to the acre? He probably would not hit it one time in fifty. He might have a few beets 5 pounds in weight, having 8 or 10 per cent in sugar, instead of growing 1 pound in weight with 15 per cent. So these things have to be learned. The chief misfortune of our beet culture in this country has been the lack of knowledge on the part of the grower; and sometimes with knowledge comes the lack of willingness to bend your back and crook your knees to give the beet the proper form of culture; but these things will come with time, and of course the yield per acre will greatly increase, until we reach a fair yield. I should say that it would be fortunate for American farmers if they can begin at 10 tons per acre over the country; and if they can do so there would be no more kicking on poor results on the part of the farmers, if they got that much, even.

(Testimony closed.)

WASHINGTON, D. C., June 13, 1900.

TESTIMONY OF MR. FRANK H. HITCHCOCK,

Chief of the Section of Foreign Markets, United States Department of Agriculture.

The commission met at 10.35 a. m., Mr. Farquhar presiding. At that time Mr. Frank H. Hitchcock, of Washington, D. C., chief of the Section of Foreign Markets, United States Department of Agriculture, was introduced as a witness, and, being duly sworn, testified as follows:

Q. (By Mr. A. L. HARRIS.) You may state your name, your address, and your occupation.—A. My name is Frank H. Hitchcock; my occupation is that of chief of the Section of Foreign Markets, United States Department of Agriculture; that is also my address.

Q. How long have you been connected with the Department of Agriculture?—A. Since the autumn of 1891.

Q. And all that time in this bureau?—A. No. I went into the Department as a biologist, passing the civil-service examination. I served in the biological work for 1 year and then took up the statistical work. I worked in the statistical bureau until about 5 years ago, when I was transferred to the Section of Foreign Markets soon after its inception. My work has therefore been statistical for about 8 years.

Q. Your examination has been exclusively in the line of the extension of foreign markets for agricultural products?—A. Yes; since I have been connected with my present office.

Q. What means have you had for procuring your information in regard to the expansion of foreign markets for agricultural products?—A. We have had, first of all, the published information that is issued by the various foreign governments. We depend upon the official reports, as far as possible, for our information, especially for our statistical information. We have also had the cooperation of the United States consular service through the courtesy of the State Department. The consuls have furnished us with reports on stated topics, the inquiries being transmitted to them through the Department of State. In addition to that we have had some assistance from employees of our own Department abroad. There have been several special agents (so called) employed to study agricultural conditions in foreign countries, and they have reported to the Department. For information on the subject of our own export trade we are of course dependent very largely upon the reports of our customs officials as published by the Treasury Department.

Q. You may state, if you will, in your own way, the past conditions of the foreign markets for agricultural products, the present conditions, and the hopes for the future.—A. The extent to which American farmers depend upon foreign markets for the disposal of their surplus products may be gathered from the fact that during the past fiscal year 1899 our agricultural exports reached in value close to the enormous sum of \$300,000,000. The agricultural exports probably comprise about 25 per cent of the total production of American agriculture. With this enormous surplus the acquirement and maintenance of a ready foreign market is of the greatest importance to our agricultural interests. In order to prevent the glutting of the home market we must ship our surplus produce to foreign countries.

During the last 40 or 50 years our agricultural exports have increased with great rapidity. In 1860 their value was about \$258,000,000; in 1870 it amounted to \$363,000,000; in 1880 to \$693,000,000; in 1890 to \$635,000,000; and in 1899 to \$793,000,000. Comparing 1860 with 1899, the last year for which we have figures, a period of about 40 years, we find an increase of over 200 per cent.

Every indication points to the probability of a still further increase in our agricultural export trade, provided proper measures are taken to foster it. Modern transportation facilities are revolutionizing the character of the trade. The introduction of cold storage and of refrigeration service on railway cars and steamships is making it possible to market in foreign countries across the sea products that we were formerly unable to export; and it is along this line of development that the increase of our export trade in agricultural products in the future may be chiefly expected—in the exportation of perishable products, such as meats, butter and cheese, perishable vegetables, and fruits.

Thus far the chief example of trade development along this line is found in the case of fresh beef. In 1880 our exports of fresh beef were valued at about \$7,000,000. Last year, 1899, they were valued at \$24,000,000.

Some of the other products that show an increased exportation, but mainly for other reasons, I will now mention. Corn is a notable example. In 1870 we exported a little over \$1,000,000 worth of indian corn. Last year we exported nearly \$70,000,000 worth. The development of the dairy industry all over the world and the discovery in foreign countries that American corn forms a cheap and desirable feed stuff for live stock have led to an enormous increase in our exportation of that grain.

Another conspicuous example of increase is wheat flour. Going back to 1870 we find that the exports of wheat flour were valued at about \$20,000,000. Last year, 1899, they were valued at \$73,000,000. The remarkable development of the milling industries in this country, resulting in a very large production of high-grade flour at a low cost, has made it possible for us to export flour in competition with other producing countries and gradually to get the trade. Flour affords one of the most notable instances of increase among our agricultural exports.

Another case of development in the agricultural export trade is that of the shipment of cattle. In 1870 our cattle exports amounted in value to less than \$500,000. In 1899 they amounted to over \$90,000,000. This trade has been greatly aided, of course, by the changes in the methods of transportation, the improvement of transportation facilities, the shortening of the time in which live cattle can be transported, not only across the continent but across the sea, and by the measures that have been taken by the Government to protect and foster the trade. The official inspection of export cattle, guaranteeing a standard in condition and quality, has greatly benefited the export trade.

Q. (By Mr. CLARKE.) What do you think it will be when beets are properly cultivated?—A. I think we will do as well as Germany. But it will be many years before we do have an average yield of that kind. I have visited hundreds of beet fields myself, and I have been surprised to see the number of poor ones. I saw thousands of acres in California last year that would not yield a ton to the acre.

Q. (By Mr. CONGER.) That was practically a failure of the crop, was it not?—A. Absolute failure, you might say. Now and then you would run across a field of 20 tons.

Q. (By Mr. SMYTH.) To what do you attribute that condition there?—A. Sometimes it is a natural condition of drought, but more often where it is not that it is carelessness in culture. Two years ago one of the land agents of a western railroad in Minnesota applied to the Department for a large quantity of seeds, which he was going to have grown along the lines of his railroad—and lands which are well suited to grow beets, too, both by location and fertility. In July of that year, at his request, I went with him on a tour of inspection to see the result. We spent a whole day hunting for beets in the grass as high as this table. We found only one plot out of fifty we visited where any attempt had been made to cultivate the beets at all. I have no doubt you can corroborate these observations in a great many localities. In that one field we found beets, splendid beets, and the others were absolutely neglected, and that has been the history of beet culture on a large scale. That is an extreme case of neglect—in the first place, ignorance. It is a pretty hard thing for even an intelligent man, if he has never seen beets grown, to prepare the soil and cultivate the beets correctly. Now, I went out the other day to plant beets on the Department beet farm—3 acres. Well, I never had set a beet drill. I did not know how to set a drill to sow 20 pounds of beet seed to the acre. I got a hard place in the road where the beets would not go in the ground, and I measured a distance—I knew the number of seeds in a pound—and I ran that drill until I got, by counting the seeds, the rate at which 20 pounds would be planted to the acre. It took me an hour to find out how to set the drill to drop these seeds. Now, suppose a farmer never made a calculation of that kind. How is he going to get the right amount of seeds to the acre? He probably would not hit it one time in fifty. He might have a few beets 5 pounds in weight, having 8 or 10 per cent in sugar, instead of growing 1 pound in weight with 15 per cent. So these things have to be learned. The chief misfortune of our beet culture in this country has been the lack of knowledge on the part of the grower; and sometimes with knowledge comes the lack of willingness to bend your back and crook your knees to give the beet the proper form of culture; but these things will come with time, and of course the yield per acre will greatly increase, until we reach a fair yield. I should say that it would be fortunate for American farmers if they can begin at 10 tons per acre over the country; and if they can do so there would be no more kicking on poor results on the part of the farmers, if they got that much, even.
(Testimony closed.)

WASHINGTON, D. C., June 13, 1900.

TESTIMONY OF MR. FRANK H. HITCHCOCK,

Chief of the Section of Foreign Markets, United States Department of Agriculture.

The commission met at 10.35 a. m., Mr. Farquhar presiding. At that time Mr. Frank H. Hitchcock, of Washington, D. C., chief of the Section of Foreign Markets, United States Department of Agriculture, was introduced as a witness, and, being duly sworn, testified as follows:

Q. (By Mr. A. L. HARRIS.) You may state your name, your address, and your occupation.—A. My name is Frank H. Hitchcock; my occupation is that of chief of the Section of Foreign Markets, United States Department of Agriculture; that is also my address.

Q. How long have you been connected with the Department of Agriculture?—A. Since the autumn of 1891.

Q. And all that time in this bureau?—A. No. I went into the Department as a biologist, passing the civil-service examination. I served in the biological work for 1 year and then took up the statistical work. I worked in the statistical bureau until about 5 years ago, when I was transferred to the Section of Foreign Markets soon after its inception. My work has therefore been statistical for about 8 years.

The increase shown by the Asiatic and Oceanian trade is proportionately very much greater than the increase shown in any other direction. It is about the most interesting feature of our recent foreign-trade development.

Q. What are the branches of our trade that are increasing in the last three or four years from the Pacific coast?—A. As regards the agricultural exports, the chief articles are cotton and wheat flour. I will quote from one of my reports statistics to show how the export trade in cotton has developed. Our total exports of raw cotton to Japan, China, and Hongkong increased from 23,500 pounds in 1889, ten years ago, to nearly 119,000,000 pounds in 1898. The present trade represents the growth of little more than a decade. To show how rapidly it has developed in the last year or two, I will say that in 1897 the exports amounted to only 32,000,000 pounds, as compared with nearly 119,000,000 pounds in 1898.

Q. Have you any figures to show the increase of the production of China during this same period? Were they increasing materially in the production of cotton?—A. Not materially. Very little increase is shown by the statistics of cotton production in China.

Q. So that the inference, then, is that they are wearing more cotton, they are consuming more cotton goods?—A. The raw cotton. I will say, goes chiefly to Japan, where the manufacturing of cotton is rapidly coming into great prominence. The Japanese are now manufacturing enormous quantities of cotton goods. Their manufacturing has increased very rapidly in the last few years, and they are now drawing upon us quite extensively for their raw cotton. The natural inference would be that the use of cotton cloths is increasing in that portion of the world.

Our gains in exportation, however, are not confined entirely to the exports of the raw product. Our exports of cotton manufactures to the Orient also show a considerable increase. They have fluctuated considerably from year to year, but taking 1889 to 1898, a period of ten years, we find an increase from \$1,600,000 worth in the former year to \$5,300,000 worth in the latter year.

Q. Just in 1 year?—A. No, in 10 years.

Q. In 10 years an increase of 4,000,000. Well, is this a peculiar kind of cotton goods?—A. It is the style of cotton goods, of course, that is generally sent to tropical countries, largely cheap cottons of the coarser grades.

Q. From what section of the United States are these goods exported?—A. They come from the cotton manufacturing sections in New England and also from the South. I do not know as to the exact distribution, but I understand that the South is now beginning to export quite largely to the Orient.

Q. The South is manufacturing an article that is very largely consumed in the Orient, is it not?—A. I understand it is beginning to.

I spoke also of the exportation of wheat flour to the oriental countries; I will quote statistics to show the gain in the shipment of that product. In 1889 our exports of wheat flour to Japan, China, and Hongkong amounted to 408,000 barrels. In 1898 they amounted to 1,120,000 barrels. The increase was particularly marked in the last few years of the decade. In 1894 they had increased to only 676,000 barrels; the advance to over a million occurred in the years following that.

At Senator Kyle's request I will now take up the leading products I have mentioned as showing gains in exportation and state briefly the principal destinations to which we are now sending them. Indian corn is the first item on my list. I will ask Senator Kyle whether he would prefer to have me state the distribution by quantities or by values?

Senator KYLE. I think value probably would be a sufficient indication.

Q. (By Mr. A. L. HARRIS.) Have you the bushels or weights in your statement?—A. I have both quantity and value wherever they can be stated. In the case of some items—for instance, fruits—only the value is recorded.

Q. (By Mr. FARQUHAR.) In the case of cereals, however?—A. The separate cereals are all stated by both quantity and value. To get at the volume of the exports it would be important, of course, to have the quantity as well as the value; but where you are simply showing the proportion of export trade that goes to the different countries the value forms a satisfactory basis as regards the distribution. In fact, it makes very little difference in a given year whether we take the quantity or the value for that purpose. Such statements, whether stated in quantity or in value, are merely comparative. However, I can quote, if you wish, both quantities and values.

Mr. FARQUHAR. I think the commission would like to have both the quantity and the value.

WITNESS: To give a fair idea of the distribution I will take the average for the 5-year period 1894-1898, stating the quantity and value for that period.

Speaking now of indian corn, our shipments of this grain to the United Kingdom

averaged 50,000,000 bushels a year, the value being about \$18,000,000. That gave the United Kingdom, taking the percentage of quantity, about 43 per cent of the total exports. Germany ranked next to the United Kingdom as a market for our corn, taking about 20,000,000 bushels a year, or about 17 per cent, the value being slightly more than \$7,000,000. Canada was a market for about 10,500,000 bushels, the value being about \$3,700,000—Canada took about 9 per cent of the total. The Netherlands, with 10,400,000 bushels, valued at \$3,800,000, received nearly 9 per cent. Denmark took nearly 8 per cent, receiving about 9,000,000 bushels, with a value of about \$3,000,000. These five countries—the United Kingdom, Germany, Canada, the Netherlands, and Denmark—were the chief markets for our indian corn during the period under consideration. After these countries France and Belgium may be cited as the most important markets.

Wheat flour is the next item that I will mention. Of the wheat flour exported in the 5-year period 1894-1898, the United Kingdom took about 58 per cent. The quantity sent to that country was, taking the annual average, about 9,000,000 barrels, and the value about \$35,000,000. Other destinations, the chief of which, however, the Netherlands, took only about 6 per cent, were, in the order of their importance, the Netherlands, Hongkong, Brazil, Canada, the British West Indies, Cuba, and Germany. I have mentioned all the destinations to which an average annual export of more than 200,000 barrels was sent.

Q. (By Senator KYLE.) Did you mention the Asiatic countries there in that list?—A. I mentioned the chief one—Hongkong. Hongkong ranks third.

Q. About what per cent?—A. It takes about 5 per cent of the flour.

Q. I would like to ask you whether the East Indies are finding a market for wheat and wheat flour in the Orient?—A. My impression is that they are not to any considerable extent. You refer to India?

Q. India; yes.—A. Not to any large extent. India is not developing as a wheat-exporting country. That country has not the importance that it formerly had as a source of supply. I have here the wheat production of British India. It fluctuates, of course, from year to year, but the general tendency has been downward.

Q. You may state for the information of the commission something about the production of British India.—A. There have been indications that the wheat production of India was declining, if anything, in recent years. For instance, the average annual production for the past 5 years, 1895-1899, amounted to something less than 230,000,000 bushels, whereas the average for the preceding 5 years, 1890-1894, was about 240,000,000 bushels. The average for the 5 years 1885-1889 was still larger, amounting to about 260,000,000 bushels.

I was about to speak of the distribution of our export trade in cattle. The United Kingdom takes nearly 95 per cent of the live cattle shipped from the United States. The average number of head exported to the British market during the 5 years 1894-1898 was about 350,000 and the value about \$33,000,000. It is the only market of importance we have for export cattle. The remainder of the trade is widely distributed among other countries.

I will mention as an interesting fact that we have recently been shipping quite a number of cattle to Cuba. In 1898 we shipped about 40,000 head. The importation of American live cattle into Germany, France, Belgium, and the Netherlands was prohibited some years ago, although I should say that Belgium has since removed the prohibition.

Q. (By Mr. A. L. HARRIS.) What was the reason of the prohibition?—A. The prohibition was enacted on the supposition that there was danger of introducing infectious diseases. Several years ago—I believe it was in 1894—there were some alleged cases of Texas fever in American cattle shipped to Hamburg. On the strength of that Germany prohibited the importation of live cattle from the United States, and these other countries afterwards took similar action.

Q. What action has been taken, if any, on the part of our Government to insure against the disease of Texas fever in the shipments from this country?—A. The inspection system of the Department of Agriculture is believed to be a very sure preventive of the exportation of diseased cattle. I think there is little danger of sending diseased cattle out of this country under that system.

Q. But so far you have not been able to convince those countries that there is no danger?—A. There has been a great deal of correspondence between our Government, through the State Department, and foreign governments on that subject, but it has been very difficult to convince them. I do not know whether I should say this formally or not. I should like to say to the committee, informally, that it is believed to some extent that the restrictions put upon our exports are simply a pretext to keep them out in order to prevent competition. That is one reason why it has been so difficult to get some of these restrictions removed.

Q. (By Mr. FARQUHAR.) Is the action of Germany traceable to the so-called

Agrarian party, or the Farmers' party, in the exclusion of the American product?—A. It is generally believed that the Agrarians are back of all these movements against our products and that the real object is not so much to protect the German people from injury through disease as it is to protect their products against competition.

Q. (By Mr. A. L. HARRIS.) Where is the estimate of value placed, here in this country or where the cattle are delivered?—A. In the statistics I am quoting the value is the declared value here.

Q. (By Mr. FARQUHAR.) In the American custom-houses?—A. In the American custom-houses. I am now using United States statistics. The Germans in preparing their statistics of importation take the value in their own ports, based on the market price.

The next product I have on the list is lard. The United Kingdom is also the chief market for our lard, Germany ranking second. A large part of the lard is sent to those two countries. During the period 1894-1898 the United Kingdom annually took about 194,000,000 pounds on the average, the value being about \$13,000,000. Germany took during the same period about 144,000,000 pounds, valued at \$9,000,000. The United Kingdom's proportion of our total lard exports was 36 per cent and Germany's 27 per cent. We also shipped considerable lard to the Netherlands and Belgium. The average yearly shipment to the Netherlands was about 45,000,000 pounds, with a value of \$3,000,000; that to Belgium was about 33,000,000 pounds, valued at about \$2,000,000. The Netherlands took about 8 per cent, and Belgium about 6 per cent, of the total. Among other countries to which we shipped in lesser quantities were Cuba, France, Brazil, and Denmark.

Q. (By Senator KYLE.) What percentage did France take?—A. France took about 5 per cent.

Q. In your list of destinations you mention England, Germany, Belgium, and the Netherlands, and seldom ever include France among them. What is the reason that France consumes such a small proportion of American products? Do they produce largely in all these lines?—A. France, of course, is to a very large extent, an agricultural nation, producing from its own soil an abundant food supply, and so we have always found it difficult to market our agricultural products there. The difficulty is increased by rather stringent tariff legislation enacted in the interests of French agriculture. I think there is also, to a certain extent, a prejudice in France, as in Germany, against some American products, especially meat products. At any rate, it has been the history of the trade that the French have not taken their proportion of our meat products.

Q. Not even considering the question of obstruction?—A. I think not.

Q. You bring in the hog before you get through, do you not? I would like to have that next to the lard; the hog is a very important institution in this country.—A. The hog is certainly a very important institution in this country, but it is not sent out alive to any considerable extent.

Q. Goes as pork, of course?—A. It goes in the form of pork; the packing is done here. Our average annual exports of live hogs during the five years 1894-1898 amounted to only about 14,500 in number; the value was about \$144,000. They went chiefly over our borders to Mexico and Canada. We sent an average of about 10,000 head to Mexico, valued at about \$115,000; and to Canada about 2,000 head, valued at about \$11,000. We also exported an average of nearly 2,000 head to the Hawaiian Islands, the value being about \$10,000. Of the total number of hogs exported, Mexico received 67 per cent, Canada 15 per cent, and the Hawaiian Islands 13 per cent.

Our exports of fresh pork averaged only a little over 3,000,000 pounds a year and went chiefly to the United Kingdom, the shipments to other countries being inconsiderable. The total value was about \$220,000.

Of pork, salted or pickled, we exported about 70,000,000 pounds a year, the value being about \$4,000,000. Of this product the United Kingdom took 23 per cent, the amount being about 15,000,000 pounds and the value about \$1,000,000. The remaining exports of salted or pickled pork went chiefly to Haiti, Canada, British West Indies, Porto Rico, British Guiana, and Germany.

Q. Germany comes last in the list in regard to importance?—A. I have named only the most important countries; there are many other countries, of course, of lesser importance.

Q. Is Germany named in the order of importance?—A. Yes; they were all named in the order of importance.

Q. Germany tailing the list?—A. Germany took a little over 3,000,000 pounds a year during that period, the value being about \$200,000. Germany's share was less than 5 per cent of the total.

Of bacon we exported annually about 490,000,000 pounds on an average, and

the value was about \$33,000,000. The United Kingdom took of this amount about 77 per cent, or 377,000,000 pounds, valued at \$30,000,000. We sent 31,000,000 pounds, or about 6 per cent, to Belgium, the value being \$2,300,000; to Germany we sent about 5 per cent, or 23,000,000 pounds, worth \$1,500,000. We shipped about 16,000,000 pounds to Brazil, or slightly more than 3 per cent, the value being \$1,200,000. The Netherlands took about 2 per cent, or 11,000,000 pounds, valued at \$900,000. These five countries were the leading destinations.

Of hams we exported about 137,000,000 pounds a year, the value amounting to about \$13,700,000. The United Kingdom took 111,000,000 pounds, valued at \$11,000,000, this being 81 per cent of the total. After the United Kingdom, Belgium was the most important market, taking about 8,800,000 pounds, valued at \$880,000, or about 6 per cent. We shipped about 4,000,000 pounds a year to Cuba, the value being \$435,000; Cuba took about 3 per cent of the total. To Germany we also sent about 4,000,000 pounds, or 3 per cent, the value being \$383,000. To Canada we sent about 2 per cent, or 3,000,000 pounds, worth \$292,000. The only other country that took hams to the extent of 1,000,000 pounds a year was the Netherlands, the shipments to that country averaging about 1,400,000 pounds, or slightly more than 1 per cent of the total, the value being about \$147,000.

Another item I mentioned as being of interest because of the rapid growth of its exportation was oil cake and oil-cake meal. The exports are recorded under two heads, oil cake and oil-cake meal made from cotton seed and that made from flaxseed or linseed.

As to the cotton-seed oil cake or oil-cake meal, we shipped of this product annually during 1895-1898 about 609,000,000 pounds on an average, the value being about \$5,400,000. It was sent chiefly to Germany and the United Kingdom, the former country taking about 47 per cent of the total, or 289,000,000 pounds, valued at about \$2,600,000, and the latter country, the United Kingdom, about 27 per cent, or 165,000,000 pounds, valued at \$1,400,000. After these two countries the most important market was Denmark, which took on an average about 11 per cent of the total, or 66,000,000 pounds, worth \$585,000. To the Netherlands we sent 57,000,000 pounds, worth \$518,000, or about 9 per cent; to Belgium 17,000,000 pounds, worth \$150,000, or about 3 per cent; and to France 12,000,000 pounds, worth \$100,000, or about 2 per cent. The shipments to other countries were comparatively unimportant.

Now, taking up flaxseed oil cake and oil-cake meal, we sent of this product to foreign markets about 377,000,000 pounds, the value being close to \$4,000,000. The United Kingdom received about 48 per cent, or 181,000,000 pounds, valued at nearly \$2,000,000; Belgium about 26 per cent, or 98,000,000 pounds, valued at \$1,000,000; the Netherlands about 14 per cent, or 54,000,000 pounds, worth \$371,000; and France 5 per cent, or 17,000,000 pounds, valued at \$172,000. To Germany we shipped 12,000,000 pounds, or about 3 per cent, the value being \$126,000. We also sent about 3 per cent to the British West Indies, which took 11,700,000 pounds, worth \$186,000. These were the most important markets for flaxseed oil cake and oil-cake meal.

I also mentioned cotton-seed oil, stating that the exports of this product amounted to about \$12,000,000 in value for the year 1899. The average for the 5 years 1894-1898 was about \$7,000,000 in value, and in quantity about 25,000,000 gallons. Of these exports, we sent to France 6,700,000 gallons, worth \$1,800,000, or about 27 per cent of the total.

Q. (By Mr. KENNEDY.) There must have been a remarkable growth in the exportation of cotton-seed oil; for the year 1899 you say it was \$12,000,000, while the average for the 5 years 1894-1898 was \$7,000,000. Where did the increase come; all along, or was it remarkable for any one or two years?—A. There was a marked increase in 1898 and 1899. There was a considerable increase in the preceding years, but in the last two years there was a very decided increase. The quantity exported increased from 27,000,000 gallons in 1897 to 40,000,000 gallons in 1898 and to 51,000,000 gallons in 1899.

Next to France in importance as a market for cotton-seed oil come the Netherlands, to which country we exported during 1894-1898 an average of about 5,800,000 gallons a year, or about 23 per cent, the value being nearly \$1,800,000. After France and the Netherlands, which took over half of the total, the principal markets were the United Kingdom, Germany, Austria-Hungary, Mexico, and Italy. We sent to the United Kingdom about 9 per cent, or 2,200,000 gallons, worth \$595,000; to Germany about 8 per cent, or 2,000,000 gallons, worth \$648,000; to Austria-Hungary also about 8 per cent, or nearly 2,000,000 gallons, worth \$573,000; to Mexico about 6 per cent, or 1,500,000 gallons, worth \$386,000; and to Italy about 5 per cent, or 1,300,000 gallons, worth \$382,000. These were the only countries to which we sent average annual exports exceeding 1,000,000 gallons.

Another product for which I will give statistics of distribution is oleo oil. Our exports of oleo oil for the 5 years 1894-1898 averaged about 110,000,000 pounds, and the value about \$3,357,000.

Q. (By Senator KYLE.) What was the average exportation of butter during these years, and also give the valuation?—A. The average exportation of butter was 18,764,000 pounds and the value about \$2,858,000.

Q. As against 110,000,000 pounds of oleo oil?—A. Yes. Of these exports of oleo oil, the Netherlands took about 60 per cent, the average quantity being about 66,000,000 pounds and the value about \$5,000,000. Germany was the second market of importance, taking 23 per cent of the total, or about 25,000,000 pounds, with a value of about \$1,900,000. Our exports to the United Kingdom, which ranked third as a market, averaged 8,000,000 pounds, or about 7 per cent, the value being \$645,000. To Sweden and Norway we sent about 4 per cent, or 4,320,000 pounds, worth \$300,000, and to Denmark about 3 per cent, or nearly 3,000,000 pounds, worth \$233,000. Belgium took slightly more than 1 per cent, or 1,400,000 pounds, the value being \$110,000. Shipments to other destinations were comparatively small.

The oleo oil exported to the Netherlands is used chiefly for manufacturing oleo-margarine, or imitation butter, which forms an extremely important industry there. In some of the other countries I have mentioned our oleo oil is used quite extensively for the same purpose.

Q. (By Mr. A. L. HARRIS.) You may state, if you can, what effect this increase in the export of oleo oil had on the dairy interests of the country.—A. I was about to refer to the exportation of the dairy products, butter and cheese, as presenting the most striking example of decline in our agricultural export trade. I have tried to cover some of the most important instances of increase in the products I have already mentioned. Butter and cheese present the most striking cases of loss, and to illustrate the falling off that has occurred I wish to give a few figures from our export records. Going back to 1880 we find that there was an annual export of nearly 40,000,000 pounds of butter. I will give the exact figures, which are 39,237,000 pounds, valued at \$6,691,000. That year represented about the height of our export trade in butter. In 1890 the exports were 29,748,000 pounds, valued at \$4,187,000, a decline of nearly 10,000,000 pounds for the decade. In 1895 our exports had dropped as low as 5,599,000 pounds, valued at \$916,000. That was about the low-water mark in our butter export trade. For the last two or three years the trade has been picking up a little. In 1899 we exported about 20,248,000 pounds, worth \$3,284,000.

Q. (By Senator KYLE.) Still very much less than in 1890?—A. Only about one-half what we exported 20 years ago.

Q. (By Mr. A. L. HARRIS.) Is that quantity accounted for solely on account of the increase of the export of oleo oil?—A. No.

Q. To what other cause can you attribute that falling off?—A. Of course the increase in the production of imitation butter and its increased consumption abroad have naturally affected the consumption of butter, but they haven't caused this great falling off in our export trade. In spite of the increased consumption of butter substitutes there has been an increased exportation of butter from most of the dairy countries. They have increased their trade while ours has been dropping off. The chief cause of this decline is found in the unfortunate management of our export trade. The chief cause of the decline was the inferior grade of butter that our exporters sent to foreign markets, and especially to the United Kingdom, which is our chief butter market. After we had established a trade of considerable importance and created a fair reputation for our butter in the foreign market, unscrupulous exporters began to take advantage of the situation to dispose of inferior butter, and the lack of any Government inspection of export butter in this country made it possible for them to ship almost any kind of butter. What I suppose you might call adulterated butter—process butter—renovated butter—they were able to label as they pleased, and large quantities began to be sent to the English markets, and this naturally brought the American butter as a whole into disrepute. I should have said in the first place that as a rule we did not send our best butters to the British market; inferior grades that could not be readily disposed of in our domestic market were sent abroad in large quantities, and it is generally admitted that this was the cause of the loss of our export trade in butter.

Q. Any recent tariff discriminations, or anything of that kind?—A. No. Our chief market, you see, is the United Kingdom, where butter is admitted free of duty.

In contrast to this decline in our own export butter trade was the experience of certain other butter-exporting countries, and especially Denmark. In 1880, the

first year I referred to as regards our own exportations, the Kingdom of Denmark exported about 27,498,000 pounds of butter, having a value of about \$6,805,000. By 1890 the Danish exports had increased to 98,873,000 pounds, worth \$20,808,000. In 1898, the last year for which we have their export returns, Denmark exported 160,143,000 pounds, worth \$34,576,000.

Q. Where did Denmark find the market chiefly?—A. Denmark sends her butter almost exclusively to the British market—the greatest butter market of the world. Denmark caters to that market, and makes her butter with a special reference to its requirements. Only a very small per cent of Danish butter goes to other destinations.

Q. What percentage of the oleo oil does Denmark take?—A. About 8 per cent. Q. Our people, then, have discredited their own product?—A. Exactly.

The butter export trade of Denmark is practically under government supervision. It has been the policy of the Danish Government, first of all, to establish a reputation for its products in foreign markets, and then to compel its producers and exporters to maintain the high standard of those products.

Q. Please state how they succeed in enforcing that requirement. Do they have inspections at the borders?—A. Yes; the butter for export is carefully inspected, under the direction of the Royal Agricultural Society, acting for the Government, and no butter is allowed to go out of Denmark that does not come up to the required standard. It is a remarkable fact that Danish export butter is all of one grade. The importers in England simply give an order for so much "Danish butter" at the market quotation. This fact speaks volumes for the character of the product that is shipped from Denmark.

Q. (By Senator KYLE.) Very similar to our buying the Elgin butter in this country, is it not?—A. Somewhat similar to that, perhaps.

Q. Elgin creamery butter—people know what that means when they ask for it and pay for it?—A. Yes; but in the case of Danish exported butter the British purchaser practically has a government guaranty that the butter will be of a certain grade and up to a certain standard.

Q. What have you to say in reference to the United States inspection?—A. We do not have any such thing as regards export butter, and that is the great difficulty; that is exactly what we need. I believe we should have a system of Government inspection for dairy products similar to that applied to our meat exports; and, in fact, our Secretary of Agriculture, Mr. Wilson, in his last annual report recommended that such a system be established, requiring our export butter to be inspected and labeled as to grade and sent abroad with the Government certificate upon it, guaranteeing to the foreign purchaser that the butter is of the grade claimed by the exporter, and thus preventing the fraud now possible in the exportation of this product.

Q. And that it is butter and not oleomargarine?—A. Certainly.

Q. It would be a very good thing if we could get the same guaranty for the American consumer?—A. Yes.

In Canada they are adopting a policy very similar to that in vogue in Denmark.

Q. (By Mr. KENNEDY.) Where does the Canadian butter go?—A. It also goes chiefly to England.

Q. (By Mr. FARQUHAR.) How many years is it since Canadian butter and cheese have run American butter and cheese out of the English market?—A. I spoke of 1880 as being within the period of our greatest development in the butter trade.

Q. That was the high-water mark?—A. As regards butter, yes. I do not refer to Canada as a competitor in the butter export trade especially. It is in the cheese export trade that we have lost to Canada. The Danes have developed the butter export business much more extensively than Canada, although latterly the Canadians are taking steps to push their butter export business just as they have been doing with the cheese export business.

Q. Can you give figures to show how far the Canadians have come into the United States market with butter product, even as against the tariff?—A. Only to a very small extent. I have not the exact figures here. Their total exports of butter are not large, however, although they are now beginning to develop. In 1899 Canada exported to all destinations about 20,000,000 pounds of butter, the value being about \$3,700,000. In 1890 very little export business was done, less than 2,000,000 pounds going abroad. The Canadian trade fell off at about the same time as that of the United States.

Q. And fell off for the same reason?—A. Presumably the same, although I have not looked into that matter so carefully.

I will quote now the 1880 figures for Canada. In that year Canada exported 18,535,000 pounds of butter, worth about \$3,000,000. In 1890, as I have said, the shipments dropped to less than 2,000,000 pounds, the value being only \$340,000.

In 1899, under the measures taken to reestablish the butter export business, the amount shipped came up to about 20,000,000 pounds. In other words, the Canadians export about as much now as in 1880. That is the history of their trade. Their efforts to push the butter export business are comparatively recent, much more so than their efforts to push the cheese export trade. They are now taking measures similar to the Danish methods to put their butter into the British market, and that is one reason why it is very important for us to take some such measures.

(At this point the commission took a recess until 2 o'clock, and requested Mr. Hitchcock to continue his testimony at 10 a. m. Friday, June 15, 1900, at which time the hearing was continued, as follows:)

Q. (By Mr. A. L. HARRIS.) Professor, the other day you were testifying in regard to the decline of dairy products. Have you anything more to say in regard to the cause of the decline in dairy products?—A. I called attention to the fact that there was a very remarkable falling off in our exports of butter, beginning soon after 1880, when the trade had reached its high-water mark. I explained that this decline was largely due to the shipment of an inferior and in some cases an adulterated product. In contrast to the falling off in our own export trade in butter I mentioned the remarkable development of the export trade of Denmark, where it has been the policy to permit the shipment of no inferior products. The Danes started in to establish a reputation for their butter, and, having established it, they took measures to maintain it, and the result has been the remarkable growth of trade that I set forth statistically. I also mentioned the fact that Canada has recently taken measures to extend her export trade in butter, and with marked success. I wish also to mention the case of the Australasian colonies of Great Britain. The butter exports from these colonies to the United Kingdom, which is their chief market, increased from less than 4,000,000 pounds in 1889 to over 40,000,000 pounds in 1899. In Australasia measures similar to those carried out in Denmark have been adopted, and results almost as notable in the way of increased trade have followed. Other countries that have developed an important export trade in butter within the last decade are Sweden and Finland. These countries produce a butter that is practically the same as Danish butter, and they are shipping it now to the British market in increasing quantities each year. I should explain that quite a large quantity of this butter from Sweden and Finland has hitherto gone to Denmark, being practically the same thing as Danish butter, and a considerable portion of it has undoubtedly been reexported by the Danes as their own butter, with which it is to all practical purposes identical. Even Russia is also beginning to develop an export trade in butter. The Baltic provinces, especially, are giving their attention to this industry, and are taking active measures to develop it—measures similar to those taken by Denmark. The Russians are engaging Danish experts to install their creameries and to instruct their butter makers. Already they are beginning to ship a high grade of butter, some of which is sent to the British market, and finds there a ready sale.

These various countries, none of which has greater dairying possibilities than the United States, are thus developing and widening their export trade in this commodity, while we, because of our unbusinesslike methods, have been losing the little export business that we formerly possessed. I believe that this product as a factor in our export trade should receive special attention. I think it would be profitable to take measures to develop an export trade in butter.

Q. Could that be best accomplished by legislation, or do you think voluntary associations could bring about the result?—A. I think that legislative aid would be of great assistance. I am strongly in favor of official inspection of exported butter. I think that is the most feasible plan for preventing the shipment of inferior produce.

Q. You would recommend an inspection similar to that that is now required for our meat products?—A. Yes; the same system could be extended so as to include butter and other dairy produce. As I stated at the last hearing, the Secretary of Agriculture has made the recommendation that butter and cheese and milk for export be subjected to an official inspection, that a grade be established, and that produce that comes up to that grade be certified to by the Government inspector, labeled, and the Government certificate placed upon it as a guaranty to the foreign importer of its quality. Such a measure is very strongly recommended by the Department, and I think that it would meet with the approval of the dairying industry. Some inquiries have been made in this regard and the general feeling, as far as tested, seems to be in favor of Government inspection for these products.

Q. (By Mr. FARQUHAR.) Are you through with the butter?—A. Not fully.

Q. Has the Department of Agriculture made any investigation as to the process

of manufacturing butter in Denmark and Sweden in comparison with America and Canada?—A. Yes.

Q. Have you any sufficient, obtainable reports to show the difference in the quality of the milk and cream that enters into the manufacture of the butter?—A. Several years ago the Department sent a special agent to Denmark to investigate the dairying industry. The agent was commissioned toward the close of Secretary Rusk's administration, as I remember. He went to Denmark and spent several months there investigating the dairy methods, and afterwards made a very thorough and comprehensive report, which was published in the last Administration. The Department has not made similar investigations in the other countries you have mentioned.

Q. Was the Denmark manufacture at that time as far progressed as it is now, as perfect?—A. Probably not as perfect, because the Danes are perfecting their system every year, but it had reached a condition that made it rank as the foremost in the world. The Danes are regarded as the pioneers to a certain extent in butter production by modern methods. They have been the models, not only as regards production, but as regards export methods, for these various other countries I have mentioned—these countries that are now developing very rapidly an export trade in butter.

Q. Do you know whether the Danish butter is made from the sour cream or just simply from the milk after having extracted the cream from it, what we call the body of the milk?—A. I am not an expert in the dairy business, but I understand that the Danish butter is made almost altogether from pasteurized cream; a very large percentage of the Danish butter is pasteurized, and to that fact is attributed its remarkable uniformity.

Q. In other words, it is a cream butter?—A. Oh, yes; it is a cream butter.

Q. Is it possible under any inspection for the American butter to compete with the cream butter of Europe? Has the Department discovered that, or has it gone into the investigation of it?—A. The Department thinks it is possible for us to put a butter into the British market that is equal in quality to the Danish.

Q. Certainly, provided that they take the same class of cream to make the butter, but no other way?—A. Of course, it goes without saying that they would have to use an equally good material.

Q. Is it not a fact that you have investigated that really the Americans are putting a butter there that has not the full fatty substance of butter and is not perhaps equal to the cream butter of Europe, to the English, Scotch, Irish, or Danish?—A. In the past that was the great difficulty with our export trade. Our butter was often of an inferior quality. That can not be denied.

Q. Inspection would not improve it?—A. Inspection would not improve the inferior butter, but the idea, as I understand it, is to establish a high grade. Butter that reaches that grade will carry a certificate. Inferior butter will go without a certificate. The foreign importer, knowing that we are certifying to the grade of high-class butter, will naturally demand butter bearing such certificate. The inferior butters will therefore be at a great disadvantage. At present they are not at such a disadvantage, for the reason that neither the inferior nor the best butter bears any distinctive label or anything to guarantee that one is inferior and the other high grade.

Q. All the Danish butter is labeled in the London market?—A. All the Danish butter that is exported is of a certain grade, a high-grade butter. It is called Danish butter; it is purchased in England simply as Danish butter. The English buyer merely orders so many pounds or casks of Danish butter, and that is the extent of the contract. He pays the price quoted in the market on the day of his purchase.

Q. Are you aware that there is a very wide difference in the price of butters, between the high-grade British and Danish and the ordinary American and Canadian?—A. There is a difference of 3 or 4 cents a pound.

Q. Do you mean pennies or cents?—A. I mean cents; I am quoting in United States money. There is a difference of 3 or 4 cents a pound. The import price in England of Danish butter in 1890 was 23 cents a pound. That was the average import price of all the Danish butter sent into the United Kingdom during the calendar year 1890.

Q. That is what is called 11 pence half-penny a pound, British figures?—A. The price averaged 22.95 cents for the entire year, but the quotation would naturally vary somewhat from day to day.

For the same year, the calendar year 1890, the butter imported into the United Kingdom from the United States averaged 19.2 cents per pound, and the Canadian butter imported into the United Kingdom averaged 19.4 cents per pound. In that year the Canadian brought a trifle more than the United States butter; but

you see there is a difference of nearly 4 cents between the price of the Danish and the United States and Canadian butter.

Q. Is it not also a fact that the Danish butter holds its price in the market almost against any changes, and it is a very high price, while there are fluctuations in the butter that comes from the United States and Canada?—A. The Danish butter is noted because of its uniformity; the high price is uniformly maintained. I do not mean to say that the same price is maintained, but I mean to say that Danish butter has a high price always, as compared with the price of other butter. The Danish butter brings the highest price of any butter imported into the United Kingdom, except the fresh butter. The fresh butter that comes in from Normandy brings a higher price, of course, but that is a peculiar trade. The Normandy butter comes in within 24 hours from the churn, and is perfectly fresh. It is unsalted, while the Danish butter, like the other imported butters, is a salted butter.

Q. (By Mr. A. L. HARRIS.) Do the same conditions exist in regard to cheese, substantially, that you have described in regard to butter?—A. In our exportation of cheese we have had practically the same experience as that described for our butter export trade. In 1881 our exports of cheese reached the highest figures ever attained, amounting to 147,996,000 pounds, having a value of \$16,380,000. From that time the exports declined. In 1890 they had fallen to 95,376,000 pounds, valued at \$8,591,000; and in 1899 they amounted to only 38,199,000 pounds, valued at \$3,316,000. During the past 20 years there was a loss of over 100,000,000 pounds in our export trade in cheese, and the reason for this was essentially the same as that given for the decline in our exportation of butter, namely: The shipment of an inferior product, chiefly the shipment in large quantities of so-called filled cheese. Soon after 1880 it became the practice to export filled cheese. This adulterated product was sent abroad in the guise of first-class or full-cream cheese. The result was that the British purchaser very soon discovered that he was being defrauded. The inferior quality of the filled cheese soon became known in the British market and our trade began to fall off. Our export trade in cheese was lost to Canada, where measures were taken to prevent such an experience. The Canadian government not only prevented the manufacture of filled cheese, but took measures to improve the quality of the Canadian product and to secure its ready sale in the British market. They saw an opportunity to establish a trade when that of the United States began to fall off, and they made the most of it, as is shown in a striking manner by their export figures. In 1880 Canada shipped abroad 40,369,000 pounds of cheese, valued at \$3,893,000. In 1890 the trade had increased to 94,260,000 pounds, having a value of \$9,372,000. During the past year, 1899, the exports of cheese from Canada reached the enormous total of 189,828,000 pounds, having a value of \$16,777,000. In the space of 20 years the Canadians increased their shipments from about 40,000,000 to nearly 190,000,000 pounds.

Q. How do you account for that enormous increase on the part of the Canadian export of cheese?—A. That increase is accounted for very largely by measures taken by the Canadian government to develop the cheese industry and to establish an export trade. The Canadian government began by helping the manufacturers. It gave liberal bonuses for the building of factories and, under the supervision of the ministry of agriculture, established a system of instruction and inspection that brought about a rapid improvement in the methods of cheese production. As the surplus above domestic requirements increased, the government took measures to place that surplus in the foreign market by securing for the exporters favorable transportation facilities. And while I am discussing what has been done by the Canadian government for the cheese export trade, I wish to include also the export trade in butter, because the measures taken by Canada for the shipment of butter and cheese naturally go hand in hand.

Q. There is a possibility then of having a system of inspection that would insure a pure cheese?—A. The inspection system that I spoke of would be particularly valuable in the case of cheese, for the reason that no filled cheese would go out as honest cheese under the government certificate. The probability is that after the system of inspection had become introduced the filled cheese exported would be at such a great disadvantage without a certificate that it could not maintain its market as it does now.

Q. Would this inspection be at the factory?—A. The inspection would probably be in part at the factory, just as the meat inspection is in part at the packing house.

I said that the Canadian government has assisted in the establishment of cheese factories by giving liberal bonuses, and I can also say that it has done the same as regards the manufacture of butter. It has not only done that, but it has estab-

lished a system of cold-storage transportation from the factory or the creamery to the foreign market. The measures for the development of the butter export trade began to be taken in 1896, I think. The Canadian government offered a bonus of \$100 to creameries that should install and maintain cold-storage facilities in connection with their creameries. This \$100 was to be paid during a period of 8 years, \$50 the first year, \$25 the second, and \$25 the third. The government also secured cold-storage facilities upon railroads, so that the butter after being cooled at the creamery would go directly into a refrigerator car for safe transportation to the point of ocean shipment. At the terminal of the railroad the government established a cold-storage warehouse in order that the butter could be safely kept between the time of reaching the railway terminal and the loading upon the ship. The government also secured refrigeration service on steamship lines to the British ports. This cold-storage system was installed according to instructions prepared by the department of agriculture, and, in some cases at least, Parliament defrayed the expense of installation. To give the trade a start, the government contracted with the steamship companies for cold-storage space, put in the necessary refrigerator chambers, and then guaranteed to the steamship company the full freight charges for the service. Under these conditions very favorable transportation rates were procured, and as the initial expense was borne partly by the government, it was possible for the Canadian producers to send their dairy products to the British market at very low rates. In this manner a great inducement to exportation was offered.

The Government also watched very carefully the quality of the product shipped, issued instructions as to methods of packing, branding, labeling, etc., and in fact practically supervised the entire exportation. Numerous trial shipments were also made by the Government, the Government purchasing the produce and sending it over and disposing of it through its own agents abroad. I might mention, too, that other than dairy products were shipped experimentally. Canadian fruits, for instance, were sent abroad in trial shipments.

Q. (By Mr. KENNEDY.) Is it your belief that if America is to compete with Canada for this trade in foreign markets we must copy the methods of the Canadian Government?—A. I do not think that it will be necessary for us to do what the Canadian Government has done as a whole. The Canadian Government has gone pretty far in the matter. I believe that if the trade can once be given a fair start and the American producer convinced that there is a profit in it the facilities will be forthcoming; the producers themselves will take the necessary action to get the required transportation facilities. But first of all it is important, it is necessary, to show that there is a possibility of establishing such a trade on a profitable basis. The initial experiments can very properly be made by the Government, and in fact they are in a small way now being inaugurated. The United States Department of Agriculture, by direction of Secretary Wilson, has been making experimental shipments of butter during the last two or three years, and with considerable success. We began in 1897 to send high-grade American butter in small lots to the British market. The Department purchased this butter from leading creameries in several States. In 1897 lots were procured from eleven different States, I believe, such creameries being chosen as had made a favorable reputation for their butter. Under directions from the Department this butter was put up in the form thought to be best suited to the requirements of the British market, not only as regards quality but as regards packing. The butter preferred in the British market is a mild butter, lighter than ours in color, and with less salt, and the butter sent abroad was so made. It was packed in a variety of packages, experimentally, in order to ascertain as far as possible what packages would be most desirable for future use. As a result of the experiments in the first year, the Department adopted for subsequent shipments a cubical box similar to the Australian box, but tapering slightly from top to base, in order to facilitate unpacking the butter. Aside from the taper it is identical in size and shape with the standard Australian box that is in such favor in the British market.

Trial exports have been continued during the past year, some of the shipments going to new destinations. Butter has recently been shipped to the Orient to some extent. Experimental shipments were first sent to London, then to other English cities, and later to Paris. It is, of course, only the beginning of experimentation in this line, but I think I can say that the result has been on the whole highly satisfactory. We have convinced the British butter merchants, to some extent at least, that a high grade of butter can be made in the United States, but that is equal to the best butters imported from other countries. That, of course, was the chief object of the experiment—to show the British consumer that all American butter was not inferior, but that, on the contrary, we were making

here a first-class article. These experimental shipments of butter will probably be extended, and further beneficial results are hoped for.

Q. I infer from what you said the other day about the large shipments to the Netherlands of certain ingredients which entered into the manufacture and composition of imitation butter that there must be a large manufacture of imitation butter at certain points in Europe. Can you say where that imitation butter finds a market?—A. The manufacture of oleomargarine, or artificial butter, is carried on most extensively in the Netherlands. The exports from the Netherlands exceed 100,000,000 pounds a year. Of these exports by far the largest part goes to the United Kingdom, while the remainder is distributed quite generally over Europe and also to some extent through tropical countries.

Q. So that there is a demand for that artificial butter in Europe?—A. Artificial butter is used now quite extensively in Europe; it is probably used most extensively in England and Germany; but, although the manufacture of artificial butter has increased very largely, the consumption of real butter has also increased. There is a more general use of butter throughout the world; the poorer classes of the people are beginning to use it much more than formerly, and for that reason the production of oleomargarine has not destroyed the market for butter. The United Kingdom, of course, is the important butter market of the world, and to show you what has been the increase of the demand in that market I will quote some statistics I have on the subject. In 1886, which is the first year for which we can give separate statistics of the imports of butter into the United Kingdom (prior to that year butter substitutes were grouped with butter, oleomargarine being included in the butter imports as recorded; we can not divide them prior to 1886), the imports of butter into the United Kingdom from all sources amounted to about 173,000,000 pounds. In 1899 the imports of butter into the United Kingdom amounted to about 380,000,000 pounds. Thus in a period of fifteen years the demand of the British market for imported butter more than doubled. Practically each one of the past fifteen years has shown a marked increase in the imports of butter into the United Kingdom. The increasing exports from the various countries that I have mentioned as showing rapid development are chiefly due to this growing demand of the British market. Those countries are supplying this demand; they send their butters to Great Britain almost exclusively. It is the great butter market of the world.

Q. (By Mr. A. L. HARRIS.) In the experiments in shipping that you are making in the Department, do you find the necessary conditions or facilities for cold storage?—A. There are excellent facilities on the railways of the United States. We have probably the best cold-storage transportation facilities by rail of any country, but there is a lack of sufficient accommodations on the ocean steamships. The cold-storage chambers on the steamships plying between the United States and Europe are very largely monopolized by the meat interests. They are contracted for and controlled by the packers. The meat exporters take measures to procure the amount of space required for their trade and the necessary refrigeration facilities, but aside from that industry there is not sufficient cold-storage service, and it has been found difficult at times in our experimental shipments to get the facilities needed. That is one thing, of course, that would have to be remedied. Another great difficulty is the lack of cold-storage facilities at the docks. One of the chief dangers in shipping butter and other perishable products is that they will arrive at the port of shipment some time in advance of the sailing time and become damaged during the wait. We need cold-storage facilities at the docks, so that products that are brought on the refrigerator cars can be transferred at once into cold storage, awaiting the time when they can be put aboard ship.

Q. Have you anything further on the subject of dairy products?—A. I should like to say that practically the same measures that have been taken by Canada for the development of an export trade in dairy products and in other perishable products have been taken within the last few years by the Australasian colonies.

Q. Do you think it would be advisable for the Government to give some attention to this question of proper facilities for shipment?—A. I do most assuredly think it would be well for the Government to take some measures. I do not know that it would be best for the Government to provide cold-storage and cold transportation facilities as Canada has done, but I think that the Government can very well in an advisory capacity make recommendations, and I do think that the Government should first of all take into its hands the matter of inspection. I think that is the most important measure to be taken, so as to prevent inferior and fraudulent produce going abroad under false colors, as is now possible.

Q. You touched the other day upon the subject of the grain export. Have you

anything additional to say in regard to conditions favorable or unfavorable for the exportation of grain?—A. Within the last few years many complaints have been made in foreign ports as regards the condition in which some of our grain arrives. The grains that have been complained of chiefly are Indian corn, wheat, rye, and barley. Complaints have been made as regards Indian corn, that in many cases that grain has reached the European port in a damaged condition, caused by sweating. It has been claimed that much mouldy grain has come into European ports, and not only that, but to some extent it has been claimed that grain of a grade inferior to that of the certificate upon which it was purchased has been received. As a rule our grain is sold on the certificates of inspection that are furnished by the boards of trade and chambers of commerce at the ports of shipment in the United States. The foreign importer contracts for the grain on the strength of that certificate, and under the rules adopted by our commercial bodies that inspect, the certificate is conclusive. The importer who has bought a cargo of grain upon the certificate issued by one of our boards of trade practically has no redress if to his idea the grain does not correspond to the grade that is certified to by the inspector.

It may be that there is some carelessness in the inspection of export grain in the United States, but from what attention I have given to the matter I am inclined to think that the complaints based on the ground of fraud are mostly unfounded. Unfortunately, the methods of inspection in vogue in the United States lack uniformity. Each board of trade or chamber of commerce adopts its own rules of inspection and its own regulations for grading. In most cases the grades are changed somewhat from year to year, following the average condition of the crop, but the changes made at the several ports are not always uniform. The result is that the certificates issued at different ports do not always mean exactly the same thing. Suppose, for instance, an importer buys a cargo of corn shipped from Baltimore and certified to be number 2 mixed corn, sail grade, and then a little later buys a cargo shipped from Galveston, Texas, bearing the same certified grade, and it so happens that owing to different standards of inspection the one cargo differs somewhat in quality from the other. The importer who has received one certified grade and then, under a similar certificate, receives an inferior quality, not understanding the conditions, would naturally feel that the second consignment fell short of the standard called for by its certificate.

Q. Is it possible to fix a standard grade for all the ports of the United States?—A. I believe that it would be possible.

Q. Have any steps been taken in that direction?—A. Not so far as I am aware.

Q. If so fixed would it not be much to the benefit of the exporter from this country?—A. I believe that it would be. If we could have a uniform system of grading for all ports of shipment, so that this variation could not arise under proper inspection, I think it would be a great advantage to the export trade.

Q. (By Mr. FARQUHAR.) Do not all the boards of trade in the United States endeavor to conform to the Chicago inspection and grade or the New York inspection and grade, in those two markets, at fixed prices?—A. In a general way, of course, the great ports are followed, but as a matter of fact they are not followed absolutely. Grain inspection is had, of course, at practically all of the ports. A great deal of grain is now shipped from our Southern ports, such as Galveston, New Orleans, and Newport News, and the commercial organizations that control the inspection there establish their own rules of grading, and these rules sometimes differ slightly from those in force at New York and Chicago. We made inquiries recently in regard to that very matter, and from the replies received at the Department it is evident that there is, in a number of cases, an appreciable difference between the grades established in a given year at the several ports.

Q. You are speaking of the changes that occur there in grading. Do not these changes nearly always—in 90 per cent of the cases—occur through the difference of the character of the crops of the season?—A. Where changes are made they are supposed to be based upon that very thing.

Q. It is not an arbitrary thing on the part of the inspector of the board of trade at all, but it is simply that the very grain that comes out of the very section in one year will be graded possibly below or above what it was the year before?—A. Exactly. The grades are based of course on the average crop; but the changes in the average crop are not followed as carefully in some ports as in others. We had replies from some ports indicating that the grades established there remain practically the same from year to year.

Q. They do on winter wheat, for instance; they hardly ever change. But will you not find always a great many changes there in the spring wheat because the climatic changes are so much different?—A. The changes in grading are most noticeable in corn, of course. I do not think that the changes in wheat are so

marked as the changes in corn. It has been chiefly the corn against which these complaints have been made on the ground of grading.

You spoke of the official certification. Now that is another matter that I am glad you have suggested, for it has caused a great deal of misapprehension abroad. The certificates issued by our boards of trade and chambers of commerce usually bear the inscription, "Official inspection certificate." The importers abroad quite generally understand that to mean official as applying to the Government. I find abroad a general impression that our certificates are Government certificates.

Q. And yet, practically, they are just as good as Government certificates, are they not?—A. Well, that is a question.

Q. Well, did you ever find a board of trade that did not select the very best men that could be found there as inspectors? Merit and not favoritism rules in every case of that kind, considering the millions of money that are involved in the exchanges and boards of trade.—A. That is a very general question. I am not criticising our inspection system as a whole, because I think it is a remarkably good one under the circumstances, considering the vast extent of the country, the different conditions that prevail in the different sections, and the wide distances between the various ports. I think that on the whole the system is an admirable one.

Q. (By Mr. A. L. HARRIS.) Well, owing to the immense quantities of grain and the immense interests that are involved, would it not be better to have the Government fix the grades and have some means to protect against frauds in mixing, etc., and in bills of lading, owing to the fact that it is discredited? That is, would it not be more satisfactory both to the shipper and to the commission man to know that the inspector was under the control of the Government?—A. I believe that it would be a great advantage to the trade if some steps were taken to secure uniformity.

Q. (By Mr. FARQUHAR.) Why would it not do for the Government to license these inspectors? That would be the way to regulate it.—A. That would be one way, of course. I do not mean to say that the Government should take the matter entirely into its own hands. I am not prepared to say that that is at present necessary, but I think it might be well to place the inspection under the general supervision of the Government so that uniform rules could be enforced. To establish an official inspection service for grain at all our ports would be quite an undertaking, and I question the immediate necessity of going so far as that.

Q. Why should it not be done, in the case of cereals and everything of that kind, just as we have in the Bureau of Animal Industry now in the case of animals, meats, and live cattle? Why is there not just as much necessity to inspect the one as the other, and why is there not just as much necessity for official inspection?—A. I am not prepared to say that it would not be a good thing. I have not reached a conclusion in my own mind as to whether it would be advisable at present for the Government to take over entirely to its own control the inspection of export grain. It is, of course, a very comprehensive system. It might be well for the Government to begin by establishing an official inspection that would be optional with the exporter. Argentina has recently done that very thing. The Argentine Government has established an inspection service for grain at its several ports, so that exporters, by paying a small fee, can have their grain officially inspected and obtain an official certificate as to its grade. The Argentine inspection is entirely optional, and it seems to me that in introducing an official inspection of export grain in the United States it would be best at the outset to make it optional rather than compulsory. I believe the advantages of the Government certificate would soon lead to its being demanded by foreign buyers.

Q. (By Mr. A. L. HARRIS.) Would the shipper or commission man object?—A. There would undoubtedly be considerable opposition to a compulsory official inspection. It is very natural to expect some opposition to such a step by the Government. There would probably be opposition on the part of those very organizations that are now controlling the inspection.

Q. Is it not almost as important as the inspection of meat?—A. I hardly think it would do to say that it is almost as important. No; I do not think that there is such a crying need for Government inspection as there was in the case of meat. There are not the same sanitary reasons for it.

Q. In other words, complaint has not become so common?—A. It has not, because the present grain-inspection system is already a fairly good one, although far from perfect.

Q. Well, would it not be an assurance to the foreign importer when he buys a cargo to know that the grade is the same without regard to the port from which it was shipped?—A. Undoubtedly.

Q. In other words, is not this the tendency now: If they find that the port at Galveston has a lower grade for low grades that go to that port for shipment, would it not generally have a tendency to discredit the grades of the whole country when they pay little attention to what section of the country the grade is shipped from?—A. It would very naturally do so.

Q. (By Mr. FARQUHAR.) Would not the establishment of Government inspection make a uniform grade all over the country—naturally tend to?—A. It should do so.

Q. And would it not give a better price for our cereals in Europe if they had the Government certificate back of them, and not that of an individual nor a corporation nor a board of trade?—A. I think that it would.

Q. (By Mr. A. L. HARRIS.) Even if it did not give a better price it would give satisfaction to the people who are buying it now?—A. I should hesitate slightly on the ground of feasibility just now. To my mind it is a question whether it would not be better to extend the system of compulsory Government inspection more gradually. Take, for instance, the dairy products, and first put that branch of the export trade on a satisfactory basis. In other words, introduce these reforms by degrees.

I want to say that of course the representatives in this country of foreign importers of grain are supposed to notify the importers whom they represent of any changes in the grading, and to give them exact information on that point, but it often happens that this is not properly done. The boards of trade themselves do not inform foreign importers of the changes. That is left to the representatives in this country of the importers, and there is often laxity about sending the proper information—at least so I have been informed on the other side.

In speaking of the damaged condition of the grain that arrived in Europe I did not mean to imply that it was exported in such condition. My own belief is that a very large part of the damage occurs on the voyage. In other words, I think that in many cases where cargoes are complained of in foreign ports the grain, when shipped from the United States, was in proper condition.

Q. (By Mr. KENNEDY.) We frequently hear of commission merchants informing shippers of produce that their stuff was received in a damaged condition, and that it is done for the purpose of cheating the farmer, the fact being that the produce more often is in excellent condition when received, but reported in a damaged condition. Is it probable that anything of that practice prevails on the other side in regard to our grains?—A. I have no doubt that there are unscrupulous people abroad, as there are all over the world, who will in some cases make unfair complaints of that kind, but I think as a rule that such cases are rare.

Q. Is it more difficult to ship shelled corn than it is to ship wheat in bulk?—A. It is more difficult. The corn gets out of condition more readily than the other grains, because its moisture content is greater. It is in the case of corn that most of the complaints have been made. Sometimes, when corn in otherwise perfect condition is loaded here in hot weather, the heat it has absorbed causes the grain to sweat and become moldy before it reaches the other side, and then the purchaser there naturally wonders whether that corn was in good condition when it was shipped. I believe, as I said before, that it is on the voyage that most of the damage is done. Much of the damage undoubtedly occurs in the case of bulk cargoes carried by tramp steamers. There are comparatively few complaints against corn carried by the regular liners, for as a rule the regular liners give greater attention to ventilation, and in fact to the care of the cargo generally. Ventilation is a very important factor in the shipment of corn. When shippers load corn into a steamer at a Southern port in hot weather, then batten down the hatches, and without any ventilation at all attempt to carry that cargo across the ocean, the chances are very strong that under such conditions some sweating will occur.

Corn is sometimes loaded into iron steamers without any protection against the heated iron sides. There should be some kind of a protection—either a board sheathing or a protection of bagging—against the iron sides of the steamer, for as she lies in port her sides above the water line naturally become very much heated by the sun, and when the corn is poured in and lies right up against these hot sides it is not strange that the contact with such heat causes it to sweat.

Then, too, corn is sometimes loaded into bunkers that are intended primarily for coal. Quite frequently on tramp steamers where they take a full cargo they load corn into one of the coal bunkers, which are, of course, amidships, and adjacent to the boilers. It is in these bunkers that I think much of the damage is done. The heat from the furnaces and boilers during the passage gradually works its way through the bulkhead, and it is not uncommon, where corn has been loaded in a bunker, to find it badly sweated, especially along the side of the bulkhead that separates the bunker from the boiler space. There the corn is often greatly

damaged. It is a question whether corn should be loaded in bunkers at all, owing to the great risk that is taken, or at any rate, whether there should not be some conditions attached as regards sheathing and ventilation. Even in the ordinary holds, remote from the boilers, unless ventilation is had, corn is apt to become heated at the top of the holds, more particularly during hot weather, because of the heat of the sun on the deck. That could undoubtedly be prevented by proper ventilation. The trouble with the tramp steamers is that they frequently go short-handed and do not have a sufficient force of men to attend to the ventilation properly. It is possible in fair weather to lift the hatches and let air into the holds where the corn is stowed, but that is often neglected. From my investigations I believe that if proper ventilation were provided a great deal of the damage that now results could be avoided. I understand that the steamers plying from Argentine ports carrying Argentine corn to Europe are now very generally equipped with ventilation facilities. That is a long voyage, and they have discovered the importance of ventilation; but it is unquestionably a fact that a great deal of the corn shipped from the United States is not properly attended to en route.

There has also been quite a general complaint against our corn abroad on the ground that it is too dirty. The foreigners say that in this regard it does not compare favorably with the corn shipped from other countries. They seem to think we are more careless, and that we take less pains to clean our corn than is the case in some other countries. It can not be denied that the corn frequently has a good deal of dirt in it, such as broken grains, pieces of cob, etc. When this occurs the danger of sweating is very much increased. The dirt fills in the interstices between the grains, thus excluding the air, and under such conditions heating naturally occurs much more readily. If the corn were cleaned more carefully before being exported there is no doubt that a great deal of loss would be prevented.

A few weeks ago I received a sample of some foreign materials that were discovered in a cargo of corn shipped from the port of Galveston, Tex., to the Free Port of Copenhagen. Mr. C. D. Hage, the director of the Copenhagen Free Port Company, forwarded to me a box containing quite a variety of metallic articles, including spikes, nails, bolts, screws, pieces of wire, foundry drippings, etc., and also other matters such as glass, pebbles, and the like, that were sent over there in a cargo of corn. [Producing photograph.] I had this material photographed, and I will hand you the photograph that you may see. The articles are shown at one-half their natural size.

Q. (By Mr. A. L. HARRIS.) Is there not danger of our grain being discredited the same as butter has been heretofore?—A. Such cases as this, of course, work very materially to the detriment of our export trade. The seriousness of this particular case will be better understood when I say that, supposing that the corn had been cleaned, the company there did not subject it to any screening, and it went out over the Kingdom of Denmark, carrying this material with it, and these nails and spikes, etc., got into the mills. If you will examine that photograph carefully, you will see that some of the spikes have been between the mill rollers and were flattened out. They did great damage to the milling machinery. The millers are holding the company liable for the damages, Mr. Hage writes me.

Q. (By Mr. KENNEDY.) That is taken from one cargo?—A. This was sent to me as a sample of material that was taken from corn sent from Galveston in one cargo. Part of that material was sent in to the company at Copenhagen by the millers.

This case shows that there is undoubtedly some carelessness. The foreign importers claim that the corn shipped as No. 2 sail grade should be much cleaner than a large part of it proves to be. The contract calls for a grain that is reasonably clean, and they naturally hold that that condition is not carried out in a case of this kind.

Q. (By Mr. FARQUHAR.) You do not know what the grade of this corn was when it was shipped?—A. I am sorry to say that in writing to me about the circumstances of this shipment Mr. Hage failed to state the grade that was certified to; but I have inferred that it was No. 2 sail grade, for several reasons: first, because that is the grade that is generally shipped to Copenhagen; and, secondly, because, if it had not been supposedly a reasonably clean corn, the company there would probably have put it through their own screening apparatus. That is, they would not have been justified in sending out an unclean grade of corn to their customers, and they would not have taken the risk of doing so. But I am sorry to say that Mr. Hage did not state that fact specifically in his letter, and I have not had time to ascertain.

It is a question where this foreign matter came from—where it got into the corn. I presume that this corn may have been simply blown without being screened; however, I do not know as to that. Some of this material was prob-

ably shoveled up with the corn when it was put into the shellers. Shellers are sometimes stationed out in the open field. The farmers bring up the corn in their wagons and dump it on the ground in piles, and then it is shoveled from the ground into the shellers. Foreign objects of a less size than the cobs readily pass through the shellers, and these objects would remain in the corn unless it were screened. It would appear, also, that the railway cars in which the grain was carried to the port furnished some of the refuse material. The cars are not always properly cleaned before the grain is loaded. The terminal warehouse or elevator may also have been at fault in this regard.

I want to say in reference to this case that affidavits were presented showing that the steamer had been carefully inspected before the cargo was received, as is the custom. The captain of the steamer made affidavit that the holds in which this corn was loaded were carefully inspected and were free from all foreign matter and in proper condition to receive the cargo. He had a certificate to that effect to show that this matter did not get into the cargo from the ship.

Q. (By Mr. A. L. HARRIS.) Are you through with what you desired to say on the subject of grain?—A. I spoke also of wheat, rye, and barley. I will just touch upon these.

Against our wheat complaint has been made abroad that it sometimes contains many unsound and burnt grains, more than would be warranted by the certificate of inspection, and also that it is sometimes deficient in weight. Recently a complaint came to the Department from abroad, alleging that some wheat had been received that did not come up to the weight called for in the contract by several pounds per bushel. I also have in mind a complaint made some months ago regarding a parcel of wheat that contained garlic to such an extent that it was necessary to reclean the entire lot before it could go into the mills. Some of the grain did get into the mills before it was cleaned, and produced, of course, a very unpleasant kind of flour.

Similarly, one of the complaints against rye imported from the United States is that it too frequently contains oats in considerable quantities, making it necessary to reclean the rye before it can be milled and made into flour. As the rye is imported for bread purposes, it is important to have it free from oats and other grain.

Our barley has also been complained about in some cases because of its dirty condition. An instance came to our notice where it was claimed that as much as 10 per cent of impurities occurred in a cargo.

According to the testimony of the foreign importers, the complaints made against American barley are mostly of recent origin. Some years ago American barley was held in high favor abroad. It obtained a market in Europe that was formerly controlled by Russia. But the importers say that within the last few years complaints against the condition of our barley have been numerous, greatly endangering our market, and the probability is that unless some measures are taken to secure more care in cleaning export barley much trade will be lost to us.

Regarding our grain export trade as a whole, I think I am safe in saying that the greatest obstacle to the maintenance and extension of that trade lies in the fact that our exporters do not always exercise proper care in cleaning the grain before shipment. In view of the increasing competition we are beginning to meet with from other grain-exporting countries, it is highly important that this ground for complaint should be speedily remedied.

Before dropping the subject of grain exports, I want to recur again to the matter of the certificates, and to repeat that it seems to me unfortunate that the certificates issued by our boards of trade should be sent out under the title of "official" inspection. [Producing certificate.] The term "official" in this case is undoubtedly misleading, and it is a question whether it would not be a wise thing to prevent further misunderstanding on that ground by prohibiting boards of trade and chambers of commerce from using the appellation "official" on their certificates. It is unquestionably a cause of much misunderstanding abroad.

Q. Do you think it conveys the idea to the foreign importer that it is a Government official inspection?—A. The foreign importer very generally believes that these certificates are issued by the United States Government. I have talked with many importers abroad who were under that impression, and who were surprised to learn that the United States Government was in no wise responsible for the certification of our export grain.

Q. (By Mr. FARQUHAR.) Does not nearly every single purchaser or Liverpool broker have his own agent in the United States here in our markets?—A. Many of the larger importers have their agents here.

Q. Those that are of any account at all?—A. Many of the large importers have

their representatives here, but these certificates, of course, pass into the hands of other buyers. The importers, in reselling their imported grain, sometimes base their contracts on the original certificate, and in such cases the secondary buyers have not the same means of ascertaining the real status of the certificate.

Q. The Government inspection would cover all doubts and would verify to the consignee or the factor or the commission merchant or the original purchaser or anyone that there was bona fide inspection here when put on board of vessels, subject, of course, to stand the transportation and delivery?—A. Yes.

Q. (By Mr. A. L. HARRIS.) Do you desire to go any further into grain?—A. One thing occurs to me that I intended to add in connection with the loading of grain. I said that it was a question whether corn ought ever to be loaded in the bunkers, since they were so close to the boilers and therefore so liable to become heated on the voyage. The same objection applies, of course, to the loading of grain in any of the holds that are adjacent to the boiler or engine space. In the distribution of the cargo the corn ought, when possible, to be loaded in holds that are remote from amidships.

Q. Would this trouble be obviated to some extent if the bottoms were controlled by Americans? You spoke a moment ago about the excellent facilities on land.—A. I have no doubt that it would be far easier to control the methods of transportation if we owned the ships. Does that answer your question?

Q. Yes; that is what I wanted.—A. Carelessness sometimes occurs as regards the stowing of grain with other merchandise in the same hold. A case recently came to my attention where a hold was partially filled with corn, and then upon that corn were stowed bales of cotton. Such a condition of affairs, of course, ought not to be permitted. It goes without saying that corn put down in the hold and then covered over completely with bales of cotton is going to sweat and become damaged. I speak of this case to suggest that there is a great deal to be considered in regulating the methods of shipping grain across the ocean.

Q. What have you to say in regard to the export of cotton?—A. The principal ground of criticism against American cotton in foreign markets is the poor packing. A great deal of our cotton is still baled in the old way. We ship it in large bales, weighing about 500 pounds, and much of it is put up in inferior baling materials. The damage that thus results is not so apparent in the United States as it is at the end of the journey across the sea. Our exporters do not seem to realize the conditions that our cotton has to meet in foreign countries. The packing is generally sufficiently strong to carry the cotton safely to the seaboard and to get it aboard ship, but when it comes to be unloaded in the foreign port great loss is apt to result. Under the rough handling to which the bales are subjected in the process of unloading from the ship's holds to the docks, the flimsy baling material becomes badly torn, and usually a large amount of cotton is shredded off and strewn along the docks. Such cotton is practically ruined, becoming waste cotton. The coverings of the bales are generally so badly damaged that before the cotton can be reshipped much patching has to be done, and often entire rebaling. Foreign importers naturally complain of this, because it subjects them to so much additional expense.

An interesting instance came to my attention while in Russia last summer where the insecure packing of American cotton resulted in a great deal of loss by theft. We send considerable quantities of cotton to Russia. Most of it is transhipped for the Baltic at such ports as Liverpool, Bremen, and Copenhagen, although within the last year or two some important consignments have gone direct to Russia, without transshipment. The United Steamship Company, of Copenhagen, has been particularly enterprising in its efforts to establish a direct service between the United States and Baltic Russia, and the boats of that company have recently been carrying cotton right through from New York to St. Petersburg. However, the chief part of the American cotton marketed in Russia still goes in the first instance to other European ports, where it has to be transhipped in order to be forwarded up the Baltic. By the time that cotton has been discharged at the Russian ports of Reval and St. Petersburg it is apt to be in very poor condition as regards the baling. From these Baltic ports it has to be sent overland by rail to Moscow, where the Russian manufacture of cotton goods is chiefly carried on. Owing to the numerous rents and tears that occur in the bale coverings because of the poor baling materials, a great deal of the cotton is lost before it reaches Moscow. It generally goes there by slow freight, frequently with many stops, and I was informed that the peasants along the route sometimes steal great quantities of this cotton from the trains at night, pulling it from the damaged bales in large shreds, as they can readily do, owing to the insecure packing. In this manner the importers at Moscow have been losing so much of their consignments from America that they are now striving, as far as they can, to

replace our cotton with that produced in southern Russia. In the south of Russia they are beginning to grow American cotton quite extensively. Some years ago they secured American seed, and already they have had considerable success in the production of our upland cotton. They take great pains to bale it securely. They use a much smaller bale than the American, and pack it so tightly and firmly that no cotton can be lost or stolen from the bale. By such methods they are gradually establishing quite a trade at Moscow, to our loss.

I spoke of this case as a rather interesting one, illustrating how a trade can be injured by neglect in providing proper packing materials. Some of our cotton growers, in order to save a few cents on a bale, make it a practice to use the cheapest possible baling materials that will carry their product to the port. While such a short-sighted practice may result in a slight saving at the outset, it is certain in the long run to do great damage to our trade. Other cases, similar to that in Russia, as regards the poor baling of American cotton, have come to my attention abroad, and I think I may say that, generally speaking, our cotton export trade is in this respect fairly open to criticism. It is to be hoped that the more general adoption of the round or cylindrical bale will remedy this obstacle to our export trade in cotton.

I have mentioned the case of cotton especially because this product is decidedly our most important agricultural export, but it does not by any means afford the only instance of this kind. There are many other cases in our export trade where failure to give proper attention to the packing of the product is working to the detriment of the trade.

Q. Then the American producer and the American shipper, you think, suffer to some extent, owing to the imperfect manner in which the goods are sometimes sent from this country?—A. Yes.

Q. And greater care should be taken along these lines?—A. Yes; it is very important.

Q. It is a very general complaint among agricultural producers that little effort is made to secure a foreign market for their products. What do you know about that?—A. I think I may fairly say that, comparatively speaking, little effort has been made in the interests of the United States farmer as regards the exportation of his produce. The manufacturer seems able to accomplish more in this direction; he seems to have facilities for pushing his trade that the farmer has not had, or at least has not taken advantage of. I think it is true that more active measures have been taken to make a market abroad for American manufactures than for the produce of American farms.

Q. (By Mr. KENNEDY.) Is not that very largely because the American manufacturers push for these markets themselves?—A. Exactly. The manufacturer seems to be in closer touch with the foreign market than the farmer. He sends his representatives abroad, establishes his agencies there, and, speaking generally, there seem to be more facilities for the extension of trade in manufactures than there are for upbuilding the agricultural export trade.

Q. Manufacturers do for themselves the work which, if done for the farmers, must perhaps be done by the Government or some other agency?—A. There is a good deal in that.

Q. (By Mr. A. L. HARRIS.) Is it possible for the farmer, owing to his interests being in the hands of so many, to take up the subject of increasing his exports, like it is for the manufacturers, where large capital is invested under one control and they can send out their agents to look after foreign markets?—A. It is certainly not so easy, and I think the question that you have put discloses the secret of the difference.

Q. Have you any suggestions to make along the line of the extension of foreign markets for farm products?—A. I believe, first of all, that in the interest of the farmer the Agricultural Department ought to be provided with more liberal means to develop, as far as may be, by governmental assistance, the agricultural export trade. I do not think that enough attention has hitherto been given by the Government to that side of the farmers' interests. We have not done nearly so much as other agricultural countries have done. I spoke of the measures taken by the Canadian government. The appropriation that enabled the department of agriculture for the Dominion to inaugurate the measures I described amounted to \$100,000, which was certainly quite a liberal appropriation. The fund that was placed at the disposal of our own Agricultural Department to make experimental shipments of dairy and other agricultural produce was only \$25,000. The Australian colonies, like Canada, have also been liberal in appropriating funds to assist the farmer in finding a profitable foreign market for his produce. I feel that much more could be done for the farmers of the United States than has thus far been possible with the scanty means placed at the disposal of our Department for such work.

* I believe in the plan of sending abroad special agents, at Government expense, to study foreign markets. I think we should have a goodly number of agents abroad, working solely in the interest of our farm products. These agricultural countries I have mentioned all maintain such agents, not only for the purpose of studying foreign markets and the opportunities they afford for increased trade, but also for the purpose of studying the export methods of other countries. Canada sent her agents to Denmark—the Australasian colonies did the same—to gather information there as to the best methods of shipping dairy and other farm produce. Now that Canada is beginning to compete somewhat with Denmark, especially now that Canada is beginning to cut into the Danish bacon market in England, the Danes are sending agents to Canada to see if there is anything in the Canadian methods of production and exportation that would be an improvement over their own.

Q. (By Mr. FARQUHAR.) Can not the diplomatic and consular service do the whole thing properly?—A. With certain modifications of the diplomatic and consular service I think undoubtedly most of the objects could be attained, but I do not think it possible as the service is now constituted. I do not believe the consular officers can render the same kind of service that could be had from traveling agents.

Q. You mean the paid agents of the Department?—A. Paid agents of the Department, sent from the Department, if possible. We have tried the consular service, and it has not been altogether satisfactory for this purpose. In the first place, a consul is obliged to remain practically all the time at his place of business—at Hamburg, or Bremen, or some other city, as the case may be—and while he can watch in a general way the trade at a single port, he has to remain right there in order to attend to the routine duties of the consular office. Unfortunately, the course of trade can not be satisfactorily investigated by a man confined to a single place. In order to get a fair idea, for instance, of the butter export trade of Denmark, it would be necessary to travel over that country, to go from the creamery to the terminal warehouse at the port, and, in fact, it would be advisable to leave the port and accompany the butter on the steamer to its place of destination. This is the plan followed by these other agricultural countries that are sending out agents. The agents are instructed to begin at the beginning and to trace the trade to its final destination, in order to gain an accurate knowledge of all its conditions. The consular officers are necessarily engrossed a good deal of the time with the routine of the consular business. As a matter of fact, they can not always take the time necessary to make a thorough investigation of special inquiries sent to them. Furthermore, a consul is appointed to represent the United States trade interests as a whole, and when the Department of Agriculture, through the State Department, as is necessary, sends to him for certain information about a particular feature of the agricultural export trade, that consul may have on file in his office, and probably has, a number of requests from other sources that take precedence, and so the Department of Agriculture has to wait. The consul's attention is necessarily divided. He is not working in the interest of agriculture any more than he is in the interest of other industries, and that, of course, is a great objection from our point of view. It is very important for us to have men abroad whom we can direct and who can work under the Department's supervision. That is the reason why I feel that we never can expect from the consular service, no matter how much it may be improved, such results as other countries are getting from the employment of agricultural experts working in foreign countries. I believe that the employment of special agents of the Department abroad is the most feasible way of getting the information we want. By placing the right kind of men in competing countries and in countries that afford us most of our markets, we can undoubtedly gather information that will be of great value in extending our trade.

To supplement the work that can be expected from these special agents, I am in favor of appointing agricultural attachés to our embassies in certain of the most important countries. I am in favor of that plan because of our experience in one case, that of Dr. Stiles, who was stationed at Berlin as an agricultural attaché. Although nominally a diplomatic official, and having from the State Department an appointment as such, he was paid by the Department of Agriculture and was under the direction of our Department. His work was of great advantage to the Department. He traveled about over Europe, as occasion seemed to demand, following the instructions of the Department in order to investigate matters affecting our agricultural export trade, and in this capacity he rendered on the whole a most valuable service. His appointment was, of course, something of an experiment, but I think that it was eminently successful. It is my belief that a few such agricultural attachés, having a diplomatic status,

could be of great service abroad to our agricultural interests. Their diplomatic status would give them certain advantages over other agents.

Q. (By Mr. A. L. HARRIS.) They would be very valuable in studying the wants and tastes of foreign people also, so as to learn the proper preparation of our agricultural products for export, would they not?—A. That is, of course, at the base of our export trade. First of all, we must put up a product that will be acceptable in the market to which it is sent. It is of the highest importance to study the peculiar tastes and requirements of the various foreign markets in order that we may know what kind of a product to prepare for export.

I spoke of the Canadian bacon trade competing somewhat with the Danish bacon trade. The Danes have been preeminently successful in meeting the requirements of foreign markets, and especially of their great foreign market, the British market. Soon after the Danes had placed their export trade in butter on a sure footing, they began to reach out after a market for bacon in Great Britain. They studied the wants of that market and they produced a bacon that met those wants. In 1880 they exported about 18,000,000 pounds of pork, chiefly bacon. In 1890 they exported 65,000,000 pounds. In 1898, the last year for which we have their figures, they exported 135,000,000 pounds, sending most of it to Great Britain. In less than 20 years they developed a trade that now amounts in value to about \$15,000,000. They did so, as I said, by studying the requirements of the British market and meeting those requirements.

Q. Are there any other countries becoming competitors of American products along the line of studying the wants and tastes and methods of supplying those wants or tastes?—A. As the Canadian people followed the Danes in their methods of exporting butter, so they have followed them in regard to the bacon export trade—the two products naturally go hand in hand. Canada took the same measures that Denmark had taken to get at the requirements of Great Britain in that product, and the result is shown by the Canadian export figures. In 1890 Canada shipped of bacon about 7,000,000 pounds, chiefly to Great Britain. In 1899, within a decade, the Canadian exports amounted to nearly 112,000,000 pounds. Our own exports of bacon, of course, are enormous, but they do not show any such growth as I have just exhibited for Denmark and Canada. In fact, there seems to be danger of a decline in our export trade in bacon. We are beginning to feel seriously the competition of these other exporting countries. The first year for which our shipments of bacon were separately reported is 1881. In that year we exported 673,000,000 pounds of bacon, valued at about \$54,000,000. In 1890, we exported 532,000,000 pounds, valued at about \$39,000,000. In 1895, we exported only 453,000,000 pounds, valued at about \$38,000,000. Last year, 1899, we exported 563,000,000 pounds, worth about \$42,000,000. While our exports for 1899 were larger than those for 1890 and 1895, you will see that they were considerably smaller than our exports in 1881, which was about the time when the bacon shipments from these other countries were beginning to become prominent. Taking the record of 1899, we find that we sent abroad in that year over 100,000,000 pounds less than in 1881, about 20 years ago. It is a question whether in the years to come we shall not feel still more seriously the competition of such countries as Denmark and Canada, and also the Australasian colonies that are now beginning to ship bacon to England, unless we take some measures to adapt our product more closely to the requirements of the British market. The bacon preferred by the British nation is what is known as the Wiltshire bacon. It is different from our bacon in being much leaner and firmer. The objection to our bacon is that it is too fat, being a corn-fed bacon. It does not bring as high a price.

Q. They prefer a streak of lean and a streak of fat instead of all fat.—A. They like a leaner bacon than ours. The Tamworth and Yorkshire swine seem to be the preferred breeds for producing bacon for the British market.

Q. (By Mr. FARQUHAR.) Is not one of the reasons that we fatten our hogs too fast, and that makes a fatter meat?—A. Yes, they are too fat; that is the chief objection.

I was about to quote the import prices in England of the bacon received from the United States, from Canada, and from Denmark. In 1899 the average annual price of the bacon imported into the United Kingdom from the United States was about 7 cents a pound, the exact quotation being 6.96 cents. The average price of the bacon imported from Canada was 7.3 cents a pound. The average price of the bacon imported from Denmark was 10.6 cents per pound. In other words, there was a difference during 1899 of about 3½ cents per pound in favor of the Danish pork over ours, which is very significant. When you consider the fact that we exported last year 563,000,000 pounds of bacon, most of which went to Great Britain, you can readily see that even a slight enhancement in the price

would have meant an enormous gain to the American farmer. If the importance of this matter could be brought home to producers in the United States, so as to lead them to change their methods of production by selecting only the preferred bacon breeds and feeding the kind of rations that will produce the bacon most highly favored abroad, it would be a most profitable lesson, I am sure, for the farming community.

The case of bacon illustrates in a very striking manner, I think, the point that you just suggested about the importance of ascertaining and meeting the exact requirements of foreign markets.

Q. (By Mr. A. L. HARRIS.) I believe you have covered all the points that I have down here, Professor, together with suggestions as to the possibilities of the extension of our markets, and I do not know but so far as additional legislation is concerned. If you have anything further, however, to suggest in regard to any remedy for the grievances that you have mentioned, the commission will be glad to hear you.—A. I spoke quite fully of what Canada had been doing, and referred in a general way to what the Australasian colonies had attempted as regards governmental control of and aid to the agricultural export trade. I should like to mention a plan that has been adopted by New South Wales, one of the most progressive of the Australasian colonies, in the interest of the export trade. In 1895 the government of that colony appointed an export board, so-called—"Board for Exports" was the official title, I believe—to take under consideration plans for the development of a larger export trade in the products of the colony. The method pursued by the board was, at the outset, to hold conferences with leading representatives of the various agricultural interests, such as the dairying industry, the meat exporters, the grain shippers, etc. The leading producers and shippers of the various export commodities were called into consultation by the board and their opinions solicited as to the best measures to be taken to assist their particular branches of the trade. As a result of these conferences a great deal of valuable and practical information was elicited, and the board, on the strength of what it had thus learned, made certain recommendations to the government, which were afterwards carried out.

In a general way the measures adopted in Australasia correspond rather closely to what has been done in Denmark and in Canada; but, if anything, the Australasian colonies have gone even further than those countries in the direction of government aid and control. New South Wales and Victoria, I think, were the prime movers in the project to assist the export trade of Australasia by State intervention, but the other colonies have been quick to see the advantages of such a movement, and they are now adopting similar provisions.

One of the first things done by the Australasian colonies to facilitate their export trade was the securing of better transportation facilities by rail from the farming districts to the ports of shipment. Cold storage on the trains was procured, as it had been in Canada, and cold-storage warehouses were established at the ports of shipment where products could be safely kept until the time of sailing. Arrangements were also made with the steamship companies to provide regular sailings from the ports to the British market and to furnish refrigeration facilities on board. Another method taken by the Australasian colonies was the establishment of cold-storage depots and warehouses at London and other British ports. Several of the colonies have depots there for their products, under the management and control of government agents, who receive the produce as it comes from the ship, keep it in cold storage when necessary, and take measures for its proper disposal in the market. The establishment of these terminal depots has undoubtedly rendered great assistance to the Australasian export trade.

The colonies of Australasia have also adopted the policy of sending agents to study the methods of other exporting countries. Their agents have come to the United States to study our methods; they have gone to Canada to study the methods there; they have visited Denmark and other countries for the same purpose; and in each instance have reported to their own governments the results of their investigations. These colonial governments have taken pains to study the methods of other countries in order to follow them, as far as it seemed wise, in developing their own trade.

The Australasian colonies have also adopted one of the most important plans inaugurated by Denmark, namely, that of offering prizes for products put up in the best shape for export. The government furnishes the producers with careful instructions as to the kind of product, style of packing, marking, labeling, etc., desired for the export trade, and under these conditions, at stated intervals, contests are held, at which liberal prizes are offered for the products that best fill the requirements. This plan of offering prizes for superior export produce, and thus furnishing an immediate incentive to the producer, was a very important factor,

it is said, in bringing the export butter, bacon, etc., of Denmark up to a high standard, and the official reports from the Australasian colonies indicate that it has also been an important factor there.

Q. (By Mr. KENNEDY.) Do you believe that the adulteration of manufactured products in America is ruining the foreign markets for those products, and that these people that you speak about seeing abroad are thus taking advantage of it to gain those markets with pure-food products?—A. Wherever we are losing trade on the ground you mention, these other exporting countries are unquestionably taking advantage of the fact. When the inferior quality of one of our products causes it to find a less ready sale in a foreign market, our competitors are quick to grasp the opening thus afforded; there is no doubt of that.

And, generally speaking, I wish to say that the question of competition in regard to our agricultural exports has only of late been assuming such great importance. It has become a more vital question within the last few years because of these very measures that are being taken by competing countries to gain and control the foreign markets upon which we have hitherto depended. The measures that I have mentioned are all comparatively recent. Foreign countries have been doing more within the last decade than ever before in the way of pushing by governmental assistance the exports of their agricultural products. It is therefore important for us to take more active measures as regards our own exports if we do not wish to fall behind. The figures that I have quoted as to the exports of butter from Denmark, Australasia, and Canada, the exports of cheese from Canada, and of bacon from Denmark and Canada, are to my mind very significant, and should serve as a warning to our own producers who depend upon the foreign market.

Q. (By Mr. A. L. HARRIS.) You think the time is coming, if not here, that the Government may well take some steps in the way of extending and holding our markets?—A. I do most assuredly. I think it is time for the Government to give the subject more active attention.

Q. Have you anything additional that you care to suggest?—A. There is one thing further that I should like to say to the committee before closing. I do not wish to be misunderstood about my reference to the consular service. I do not want to underestimate the value of the services that the consular corps can render and does render. There is no question that the consular service as at present constituted is supplying a great deal of valuable information to our exporters. I think that the services of the consuls are, as a rule, decidedly valuable, but I have been impressed with the importance of adopting some additional measures, such as are taken by the countries with which we have to compete. I am in favor of sending out as foreign agents men specially qualified to acquire information regarding the agricultural export trade. I believe that experts along that line can add greatly to the service we are receiving at the hands of the consular officials. There are also some special advantages to be gained by having a few representatives in the diplomatic service—representatives solely of the agricultural interests. There are several cases, as you know, where agricultural attachés have been appointed by other nations. One case is that of Baron Herman, here in Washington, who was appointed by the German Government as an agricultural attaché to its embassy in the United States. His expert knowledge of agricultural matters makes him remarkably well qualified for the position, and he is undoubtedly rendering most valuable services to the German Government. Only a few days ago Baron Herman called at my office to present a similar attaché who had just been appointed by the Austro-Hungarian Government as an agricultural expert at Washington. Foreign agriculturists recognize the advantage of having, in addition to the consular service, special representatives abroad working solely for the agricultural interests, and I feel that it is important for us to adopt the same advantageous measures. We should avail ourselves of equal facilities, or better.

There is another thought that has just occurred to me. It is that a great deal can be done for our export trade through the medium of the various expositions that are held periodically all over the world. I believe that it would be profitable for the Government to take even greater measures than it has in the past to have at all such expositions an ample display of our agricultural products.

In answering the interrogatories of the committee, I have not pretended to mention all the measures that might be thought of to extend our agricultural export trade. I have simply endeavored to touch upon what appeared to be the most important features of the subject as suggested by your questions.

(Testimony closed.)

WASHINGTON, D. C., June 13, 1900.

TESTIMONY OF HON. MARTIN DODGE.*Director Public Road Inquiries, United States Department of Agriculture, Washington, D. C.*

The commission met at 10.35 a. m., Senator Kyle presiding. At 2 p. m. Hon. Martin Dodge was introduced as a witness, and, being duly sworn, testified as follows:

Q. (By Senator KYLE.) You may state your full name, address, and vocation.—A. Martin Dodge, director public road inquiries, United States Department of Agriculture. I am representing the United States Government at the present time on the matter of road inquiry.

Q. (By Mr. A. L. HARRIS.) You may state how long you have been interested in the subject of the improvement of roads.—A. Since 1891.

Q. How largely have you made the subject a study?—A. Well, I have been studying the subject continuously in connection with other matters from that time on. I published a pamphlet in 1891 that was the result of some former investigations made, but nothing so very definite until that time. Since that time I have been engaged partly on my own account and partly for the State of Ohio and partly for the United States. In 1893 I was appointed by Governor McKinley to represent the State of Ohio on the general matter of road improvement, and especially in reference to any changes that might be suggested in new methods of building, and application of new power or vehicles, and also the cost per ton per mile of moving by the usual methods prevailing in the country districts with ordinary vehicles and animal power. There never had been up to that time, I think, any statement or publication of the cost per ton per mile by animal power. We had through the railroads and through the transportation companies very accurate information with reference to the cost per ton per mile by the railroads and by the steamships, but I think there never had been a publication as to the cost by animal power. I took the matter up for the commission of Ohio at that time, partly for the purpose of comparison, to see whether there had been the same improvement in the means of transportation over the common roads that had been manifest by other means of transportation. The result of that investigation showed that the average cost per ton per mile by animal power was about 25 cents, but that the cost by steam power was only one-half of 1 cent. In other words, that you could carry fifty times as far at the same cost upon steam cars as you could upon the common roads; and further comparison also showed that a still cheaper rate prevailed upon the Great Lakes by steamship, and that a thousand miles could be reached at the same cost as 250 miles with steam cars or 5 miles with animal power; or, to put it per ton per mile, it was only 1 mill per ton per mile for moving upon the average on the Great Lakes, 5 miles upon the steam cars, and 25 cents per ton per mile upon the common roads with animal power. The investigation that I made at that time was the first official investigation ever made. Before that time I had made some investigation on my own motion, because I felt interested in the subject. I had had a very large experience in handling many of the products, and had acquired an actual knowledge of the cost, as I considered it, in my own experience, and I enlarged that to the experience of others by inquiry. I also ascertained at that time, through the Mexican minister, Mr. Romero, that the cost per ton per mile in Mexico was 26 cents, and I made use of that for comparative purposes, the result of which seemed to show that there was not very much difference in the cost of transportation by animal power in our own country and in Mexico. I perhaps have answered the question.

Q. In making this investigation what kind of road for animal power did you take into consideration?—A. I took into consideration all kinds of roads, from the poorest to the best, from the long haul to the short haul—all of the distances ordinarily covered; and that is why I took this matter of Mexico, because for a number of hundred years they had been transporting from Vera Cruz to the City of Mexico all of their imports to the City of Mexico, a distance of 273 miles, and it furnished a very good test of the cost upon the long haul. I also compared the cost of transporting over the plains before the railroads were built, and I found that it was fully as high on the long haul there. Then in the country I took the ordinary hauls, varying from 1 to 10 miles, and reduced it to tons per mile to get at the result. If you wish, I will give you the process in detail.

Q. We would like to know how you reached that conclusion?—A. Well, in northern Ohio where I live, it is a dairy country. The milk of the farmers, which is their largest product, is taken either to the railroad stations for shipment, or to

cheese factories to be made into cheese and butter. The contract is usually let to the lowest bidder to gather this milk in what they call milk routes, beginning at the most distant place and gathering it up as they approach the cheese factory. It was easy, by getting at the tonnage from the cheese factories and the prices, to reduce it to tons per mile, which I did in many instances, and the quotient was almost a constant factor, did not vary but a little; and then after the cheese was manufactured in these cheese factories it was hauled to the railroad station, and there also again was competition, and it was let under such terms that it was easy to convert it into tons per mile. Also in that country in the last decade there has been a great deal of timber sold and taken away, sometimes in the shape of lumber and sometimes as timber. In most cases it was hauled by the thousands, so much a thousand feet, but that was easy to convert into tons per mile, and having obtained these facts on the various kinds of roads and various distances, I deduced the result which I have stated. Then for the shorter haul, in the city of Cleveland entirely on paved streets, or nearly so, I confined my investigations to the heavy material, such as brick, stone, lumber, and building material, such as are furnished and delivered at so much a thousand, or so much a ton. Converting that into tons per mile I found that it was close to the same average.

Occasionally I would find that the rates were as low as 15 cents a ton per mile. That was the minimum. In many instances it would go 50 cents a ton a mile. Now, this that I speak of was not under any contract for full loads; but where there were partial loads, and very bad roads, it would go to about 50 and the average on the whole was about 25 cents per ton per mile. In 1893 I first published this result, which I believe to be the first table ever published in this country or anywhere, so far as I know, giving the rate per ton per mile of transporting on the common roads by animal power.

Q. (By Senator KYLE.) Have you made an estimate of the variations between the pioneer shipments on pioneer roads and those by modern, improved roads?—A. Well, I have not gone into that comparison so thoroughly as I did into the comparison between the average by animal power and the other forms of inanimate power. Those investigations have been made, however, and I am familiar with the difference. From 10 to 15 cents is the average cost over the best improved roads. According to the consular reports it goes as low as 8 cents in European countries.

Q. Per ton per mile?—A. Eight cents per ton per mile; but in this country I think it is somewhere between 10 and 15 cents. Of course you understand that we have a very small proportion of the entire mileage of good roads. It is estimated that only 1 per cent of the entire mileage of the country has been improved so as to make the sort of road that you now speak of.

Q. There would be that variation between the old Ohio turnpike road and the ordinary dirt road, 10 to 15 cents, very nearly, would there not?—A. Probably 15 cents a ton a mile.

Q. (By Mr. A. L. HARRIS.) You say you took into consideration good roads—that is, roads in good condition and roads in bad condition and at different seasons of the year?—A. Yes.

Q. How far have you considered the subject of propelling heavy loads upon the best improved roads by animal power? I mean to say, Which is the best system of roads?—A. Ordinarily, the best road is the stone road. That is to say, the best road that has ever been put into general use. I am not certain that it is the best road that can be produced. We are making experiments on steel-plate ways. It is very likely that an improvement can be made when steel is sufficiently low so as to permit its use for that purpose. That would result in a more durable road and a road that would require a diminished power to move the vehicle, and thereby reduce the cost of transportation a good deal lower than the figures I have given.

Q. Before you leave that point, I wish you would describe your steel-plate ways for roads and the cost, if you have an estimate.—A. Yes; I have a diagram showing the substructure and the superstructure, which I submit.

Diagram showing substructure and superstructure of steel-plate ways.

Q. I wish you would give us the substructure and the amount of metal, the kind and the width of the metal, together with the paving or whatever you use for the roadbed.—A. Well, the plate way is a very simple structure, consisting of two parallel plates a sufficient distance apart to receive the wheels of vehicles of ordinary gauge. They are 8 inches in width, with a flange upon the inside instead of the outside, so the lowest part will be on the outside instead of in the middle. Then there are projecting flanges that go below the surface and are embedded into a concrete foundation. This concrete foundation is only about a foot in width, or sufficient to receive the plate and to retain it and support it without any cross-ties or longitudinal stringers. There is no perishable matter used in connection with it, but only the steel plate itself with projecting flanges, and the concrete, which is laid in trenches about a foot wide and a foot deep. Two advantages of that plate way are: First, it is durable; it will last indefinitely; there is one case in Canada where a bridge has been equipped with plate ways of soft iron instead of steel, and it has been in use for over 30 years with very little wear. Second, the vehicle moves with much less power.

Q. What is the weight of this plate per yard, or per rod, or per foot, and its thickness?—A. It is about a quarter of an inch thick, and I do not now recall the weight per yard. It has passed out of my mind. I can, however, supply those figures exactly. The cost of it would be about \$3,500 per mile; that is, at the prices prevailing before the late increase. It would be more than that now.

Q. Is that cost just for the plate or for the entire road?—A. Well, that is for the plate. The additional cost of laying it would have to be added to that.

Q. What would that be?—A. It would cost about \$5,000 a mile, complete. The space between the rails has to be macadamized, and a space about 1 foot on each side, so as to allow vehicles to approach it and leave it without difficulty. The added cost brings it up to a higher price than ought to be put in, perhaps, for the country roads at the present time. I do not recommend the use of that at the present time, and I do not think it would be the most desirable except in level countries and where they may be destitute of other means or other materials for road use.

Q. (By Senator KYLE.) Your plan is to have this condition for cars propelled by animal power?—A. It is for the ordinary vehicle propelled by any power—animal power or other power; that is, an automobile or any vehicle used on an ordinary road would go the better on this road. The tables that I have seen published by Gilmore and other engineers say it takes only one-fifth the power to move a vehicle over steel that it does over the macadam roads.

Q. You could use animal power to haul a vehicle or you could attach a traction engine if necessary.—A. Yes.

Q. (By Mr. A. L. HARRIS.) Is this estimate upon a single track?—A. Single track; yes. The turnout is provided for the same as it is on the plank roads. You probably have seen the plank roads. We make on each side about 1 foot of solid macadamized roadway so as to take the wheels out of the plate way. You may turn off at any place the same as you can on the single-track road of any ordinary description.

Q. Does the wheel have any difficulty in going over this flange?—A. No, sir; we do not find any difficulty of that kind. We make the flange only about half an inch in height, and upon the inside instead of the outside, which makes it easier to leave the track than if it was on the outside. At the same time it is sufficient to give the vehicle, or the animal, more power in a longitudinal direction.

Q. Have you tested the difference in the power of propelling the same load, the same weight, over this steel-plate way compared with the ordinary macadam road?—A. Well, I made a test at Omaha in 1898 on the exposition grounds to show what weights could be hauled over this road. I did not make the other test, but I compared it with tests that were made by other persons, and especially in testing the strength of a wagon where they had hauled a very heavy load, weighing 11 tons, and where they required 10 teams to haul the load. That was not over a macadam road; it was over a common road. It took 20 horses or 10 teams to haul this heavy load over the common road, the way that they had. I took a load of equal weight and put it upon a train of 3 wagons. It took 3 wagons to get a sufficient space to hold a load of that weight, and we hauled it very easily with one small horse, showing a proportion of about 20 to 1 in the tractive power. Now that, I think, is about the real proportion that exists, from 20 to 25 to 1. That is according to Gilmore's tables, and other experiments, I had known about this difference. The purpose of the experiment there was to show by object lesson how small a power really is required to move a vehicle on the best road that can be produced. It is very remarkable to consider how much more power is required to move over rough roads and over soft roads and over

hilly roads than is actually required to move over a smooth, straight, and level road. There is a difference of many fold in favor of the improved road.

Q. (By Senator KYLE.) Were the 20 horses able to pull this load of 22,000 pounds up hill and down, or was it on level ground?—A. Now, I did not see that test made. That was made by the Studebaker Wagon Company. I took their results. I did not see them make it, but I have the photographs that were preserved from that work as it was done before. I do not think it would have taken so many horses to move it on a level. I think they must have put on enough to move it over grades.

Q. The question came to me whether one small horse was able to move this load over any sort of a hill whatever.—A. No, I do not think it would be able to move it except on practically a level. That is, the same power would not move it. Now, this horse, I stated, easily moved it. We were all surprised to see how easily a small horse not only moved it, but started it. It takes a good deal more power to start a load than it does to move it afterwards. I believe that an animal could move fifty times its own weight. That we did not quite demonstrate, but this was about twenty-two times his weight—what was moved there. It is likely a strong animal would move fifty times its own weight. I call your attention to the fact that ordinarily the vehicle that you see moved only carries a weight about equal to the team that moves it. A team that will weigh a ton will only move about a ton; that is what you see for a load. A heavier team will move more, of course, if everything is favorable; but a load double the weight of the animals is a very large load, and you will seldom see it if you look out here or go into the country. Bear this rule in mind. You will find that the load carried is about equal to the weight of the animals that move it.

Q. Including the weight of the wagon and load?—A. Well, I do not now include the weight of the wagon; no, I do not include that, and neither did we in these experiments. The weight of the vehicle was not included. It is the net weight I speak of.

Another thing I will call your attention to. Very commonly the vehicle itself weighs about as much as the burden it carries. In other words, there is almost as much dead weight carried as there is live weight. Now, I think that is an error that can be overcome. That is to say, an improvement of the road beds will lead to an improvement of the vehicle by which it will be lightened in proportion to the burden it carries, and thus will be diminished the power required to move it.

Q. (By Mr. A. L. HARRIS.) Have you made investigation as to lightening the vehicle?—A. Well, I have made some observations and I have made some experiments. Of course what I speak of now about a change in the vehicle is a matter of the future, and may be considered experimental, but I have a profound impression to the effect that the cost of moving materials over the highways is excessive and unnecessarily high, and I spoke first of all of the fact that it figured out at the rate of 25 cents per ton per mile. I also have noticed that there has not been much of a reduction in that price covering a long period of time. Two generations ago it cost almost as much as now, and the fact that the cost remains at such a high and constant factor without change, compared with the very much reduced cost by other means, has led me to think that we could make an improvement which would help the people in the rural districts very much along all of these lines, and that is why I suggested the plate-way as one means. And then in reference to the vehicle a change should be made. The bicycle carries a good many times its own weight. That is the only vehicle you will see anywhere that carries many times its own weight. Now, if what has been done in that respect could be applied to a 4-wheeled vehicle, that would give a very great gain. I have made some experiments with models only so far, and I can say that I have produced models that would carry 20 times their weight, and I believe it is possible to make a 4-wheeled vehicle that will easily and safely carry 10 times its weight, and with the improvement of the roadbed so as to get some part of the possible gain there, together with a change in the vehicle so as to diminish the proportion of dead weight, there would be such a gain as would take off a large proportion of the cost. I estimate four-fifths of the present cost could be saved. Estimating it now at 25 cents per ton per mile, I think it can be reduced to 5 cents per ton per mile. That would then be ten times what it costs on the average for transportation on steam cars. I think that can easily be obtained.

Q. (By Senator KYLE.) Your investigations have been based upon the estimation that the roadbed was to be level? In other words, your estimation of \$5,000 a mile for the construction of this track was to make a level roadbed practically level?—A. Well, no; the cost of making the roadbed would not increase by reason

of the grade, but the power required to move up a grade would have to be increased.

Q. The point I wanted to bring out was this, whether you would, in the road bed that costs \$5,000—whether you would make cuts and fills?—A. No; that was not included; cuts and fills. I was going to say my purpose in making this demonstration was not to show or recommend that the load should be increased for 1 horse up to 11 tons, but only to show that the ordinary load of 1 ton, or 2 tons, or 3, or even 4 tons, could be moved with greatly diminished power, and then you may add again the necessary quantity of power for the grades. Perhaps you would have to double for the grades. My idea was to increase the loads somewhat and decrease the power somewhat—bring the two together. An 11-ton load would be too much of a load. You would not want to move that much. That used to be the full load for a steam car. We do not need to reach such a heavy load as that.

Q. In the fall season of the year, when the roads are solid and the farmer delivers his grain, with a good heavy team, he is able to pull up an incline of 30 degrees, probably 2 tons. That is a pretty heavy load for 2 big horses, yet I have seen them do it up an incline of 30 degrees. Now, how many tons could 2 good horses pull on a steel track up the same incline?—A. We do not get an equal gain on the grade that we do on a level.

Q. A farmer's good team can pull up an incline 2 tons. How many tons can the same horses pull up an incline on a steel track?—A. Well, I would only have to estimate that. I did not make a test upon a grade, but I do not think it would be over 50 per cent more on that steep grade. We have no means to diminish the power required to raise vertically the weight. It takes the same power to raise the weight. The aggregate power, in connection with the time required, would be the same. We can not diminish that, but we can diminish the rolling friction and the sliding friction. That is, we can eliminate the sliding friction and diminish the rolling friction so as to greatly diminish the power required to move on an ordinary level or grade. When it comes to a steep grade, we do not gain proportionately.

Q. The question is, where the economy comes in to the farmer. He would be compelled in any event to use the services of two horses and a man to haul his load of grain to market, and in case he used the improved track you mention the 2 horses would still be required, would they not?—A. No; we do not suppose he would take a larger load at any point than what he could take over the most difficult point; but ordinarily the grades are light in most of the country; at least in two-thirds of the country the roads can be made nearly level, so that with the extra energy of the horses up a small grade he can get along without doubling.

Q. Would it not be more economical to bring the roads to a grade so long as you are entering upon a public enterprise?—A. Well, of course we do recommend that it should be brought to a 3 per cent grade, if possible, but 5 per cent could be very well gotten over. I want to call your attention to the fact that I do not recommend the use of this steel plate-way except in level countries where they would be destitute of other materials to build their roads of.

Q. (By Mr. A. L. HARRIS.) You do not recommend the plank road, but you do recommend the stone road. Will you please give the commission a little information as to the best way of building the stone roads that you have in mind?—A. I did not say that I recommend the stone road for all purposes. You asked me what was the best road produced. I say that is the best road. It may be too costly to be used in some cases, and there are many cases where there is no material whatever with which we can make it. I do not necessarily recommend that, but I say it is the best we can produce, and the best way to produce it is according to Macadam's plan. That is to dispense with any foundation, so called, of large stones; to prepare the earth in proper form, and then cover it with angular fragments of rock that have been reduced to uniform size, or nearly so, and when they are so reduced and properly spread upon the roadbed under pressure with moisture, they will consolidate and form practically one sheet of rock impervious to water. The ancient theory of road building was to prepare a heavy foundation similar to what might be used for buildings; that it was necessary to sustain the burden to have some very heavy substructure, and there was a great deal of cost and unnecessary labor put into these substructures, which engineers always recommended up until the time of Macadam. He seemed to make the discovery that the angular fragments of rocks when reduced to a uniform size would consolidate without any mixture of other substances or without any filling; that they would, by a mechanical process, work one upon another under pressure and moisture, and consolidate together in such way as to fill the interstices, so that in time the mass would become solid. That served a double purpose—one of mak-

ing the roads smooth and durable, and another of throwing the water off. The three greatest difficulties we have in making the road are the frost, the water, and the grade which you speak of. Now, by this method of building the stone road out of the angular fragments we keep the water off, and also make a hard smooth surface. There are many improved methods of handling the stone, crushing, spreading, rolling, and consolidating, which have reduced the cost of producing these roads somewhat, although the cost is high yet. The State highway commission of Massachusetts that have been building for the past 4 years or more, report a cost of upward of \$10,000 per mile for their roads in sections where material is very abundant, and they have all of the best means of producing, but they have never been able to produce them at lower than \$10,000; generally cost more than that, although that includes, as I understand it, some necessary grading and the reduction of the grades to a reasonable minimum. Two years ago I was representing the Government for a short time. There was produced down here in the State of Maryland, Baltimore County, about 2 miles or so, under our auspices, a road at a cost of \$2,500 per mile, completed, of trap rock, one of the best roads I have ever seen, and is still in perfect condition, and I have never known any road to be produced as good as that at that cost. One reason why we could do that, however, was because the material was right at hand. There were old stone fences distributed along on each side, and there was no grading to be done, to speak of, no hills to be reduced, and by using that stone with the improved methods of crushing and spreading, we produced the road for about \$2,500 a mile, which is the best I have seen anywhere.

Q. Have you anything to suggest as to the most economical way of procuring labor to construct these roads?—A. Well, yes. In answering that question I would like to elaborate upon the necessity of our securing in some way a method to cheapen the cost of roads in order that we may provide a perfect system. I have already stated that only about 1 per cent of the entire mileage of the United States has been improved to anything like a degree of perfection. Ninety-nine per cent of the entire mileage is still practically unimproved. Now, considering the high cost that I referred to as being necessary to produce a high grade of road, either of stone or of steel, we know very well that we can not improve all this great mileage up to that high standard with any amount of means, or money, or labor that is obtainable. It would take an army of men, more than enough to conquer the world, and it would take a revenue more than would be required to pay and supply the armies of the world; so we know, in order to make a system complete, that we must devise means which shall cheapen the cost in some way, and the only two ways that we know of are to diminish the necessary mileage to reach the people, and then to diminish the cost per mile of building. The necessary mileage can be reduced in two ways. In the first place, the introduction of the electric cars or other cars propelled by inanimate power can be so multiplied as to serve a great many people and do a great part of the service which heretofore has been done by animal power, and by so doing it shortens the haul. We do not have to go as far with horses as we would have to do if it was not for the improvements that are reaching out. I ought to mention in this connection that the concentration of population within the last two decades has a bearing upon the subject, and will necessarily have to be considered in the improvement of the highways. We probably can't change the system as conceived and laid out. The pioneers who laid out the roads in our Western country put them about a mile apart. In the Southern States they are not so near together, but there is a very great mileage laid out with a view of accommodating a population that would be spread equally over the face of the country. Now, the change manifested in the concentration of population makes it necessary for the people raising products to take them to these great centers of population more than ever before and not to the industrial villages that were built up in the midst of rural communities. In order to bring about that result advantageously, new methods that I speak of are being brought in and it is entirely feasible to serve a great portion of the people without animal power at all. Also the increased advantages that come from this cheaper and better service will draw a portion of the remaining people to the better means of transportation. What has happened in reference to the concentration of people in cities I think will happen to those remaining in the country. We find many people still remaining in the country. These people will all be drawn gradually to these cheaper and better means of transportation that are being introduced and that we know are entirely feasible. I estimate that there will be 75 per cent of all the people living in cities and only 25 per cent remaining in the country, and this 25 per cent remaining in the country will most likely be drawn to the easy means of transportation or near the easy means of transportation, so that we can shorten the wagon haul from what it is now to a very much

shorter distance. I think that 5 miles will be considered the maximum and 2½ miles probably an average haul, and therefore that the mileage necessary to make a system of transportation so as to reach all of the people in rural districts can be built up by existing means, and the new means that we now have in reach. Now, by that method I think we can so shorten the mileage required as to make it possible to raise a sum of money sufficient to do it, and especially if we can diminish the cost per mile.

Now, particularly in reference to that matter of diminishing the cost per mile, I believe that we can utilize the prison labor of the country on this work. I have lately been in the South, where they have succeeded very well in utilizing a good deal of the prison labor for road work. In the State of New York they are now beginning in Oneida County, perhaps in other parts of the State, to utilize the prison labor, and in California they are using that labor. What I think is that the entire army of prisoners in jails, in State prisons, and also the United States prisoners, wherever they may be, could under a proper system be utilized either in working upon the road itself or in preparing materials to be used upon the road. It would not be necessary, in all probability, for us to take all the prisoners out upon the highways, maybe not any large proportion of them, but they could be employed in stockades, proper inclosures, to prepare the material, either broken stone where stone roads were to be used, or brick where brick should be used, or steel in case the steel plate should prove to be successful, as I hope and expect. So that probably more than half of our prisoners could be used just as they now are, in shops and inclosures, manufacturing these materials; and the rest of them, especially including those who were in for short terms of service, could be utilized in the actual construction. Now, I speak of this because it would be such a use of the labor as would add to the common wealth. As I understand it now, from my own investigations and the reports which I have read from your commission, there is no real gain to the country either in the various Commonwealths or in the nation at large by the application of this labor. It is complained of by manufacturers and by laboring men as a source of competition which they think is unjust and unnecessary. If it could be directed to the preparation of materials and the improvement of the roads it would obviate their objection, because it would be doing a work that is not done and that can not be done. Unless, as I said before, we can cheapen the process we can not improve all the roads. We must cheapen it. We must put them to do what nobody else can do, and I think it would not only obviate the objection—that is, so far as it could be obviated—but it would make a very permanent and substantial addition to the common wealth. You can work the prisoners a hundred years the way you now do, and there is nothing to show—no benefit, no increase. But you work them a hundred years, or a quarter of a hundred years, under the new method by which the entire army of prisoners could be employed under capable engineers and superintendents, with the improved machinery that we have for preparing material, and this very cheap transportation for taking it on the steam cars and spreading it at half a cent a ton a mile, and we will find that in a quarter of a century, or in a generation, it would make a remarkable addition to the common wealth, which would be lasting and at the same time would be beneficial to the prisoners.

You all remember, probably, when inmates of insane asylums were guarded very closely and confined in rooms, and the more violent ones put in strait-jackets. But the superintendents of these institutions at the present time find that by giving them more liberty it improves their condition of mind and they are enabled to perform useful service. They make many things, and they produce a good deal of the food that they consume in many of our institutions in Ohio. Now, there is every reason to believe that a similar treatment of the prisoners would have a beneficial effect upon their minds and that close guarding and confinement would not be found necessary.

I saw, in my observations in the South, prisoners working without any visible indications of restraint whatever. Of course there was one guard in the distance with a rifle, and a foreman of the gang that probably had a pistol in his pocket; but aside from them these men worked without any chains or balls or attachments or anything of that kind, and they worked as well as any free labor that I have ever seen, and I even thought better.

By talking with those that have them in charge, I find that they report almost the same thing that the advanced superintendents of the insane report—that by giving them a little freedom and by treating them as men in misfortune, and especially by giving them a reasonable rebate in service for good conduct, they have little trouble in their attempting to escape, and little danger. It takes no more guards, practically, and there seems to be no very great trouble in that regard.

Q. (By Mr. KENNEDY.) Was the national road built by free labor?—A. I under-

stand that it was. I have been looking up the history of the Roman roads. The Roman roads were built by slave labor and the soldiers. The Russian railroad to-day is built largely by the Russian army. I find that those peoples who have kept up large armies and have had large numbers either of prisoners or of slaves, or of men who were in charge of the State as employees, have generally put them upon the public works. The greatest works of antiquity have been produced in that way.

Q. (By Mr. A. L. HARRIS.) Will the soldiers of to-day work?—A. Well, I am not recommending that for fighting soldiers, but I have simply taken note of the fact that was unknown to me until lately, that some modern nations have taken the same view of it that the ancients used to take. I did not suppose that it was feasible, and I am somewhat surprised to find out that it exists at all; but the point I make is this: that it does not seem to be desirable, or even possible, for a nation to keep very large numbers of men without having them devoted to some useful work; and if it should happen that any nation is obliged to keep a very large army continuously on its hands during periods of peace, it would seem to be all right that they might produce roads as the Romans did, or as the Russian soldiers are doing to-day. Of course we have no such case as that. I only suggest it as being a part of the consideration of what should be done with public works and with men whose labor is at the disposal of the public officers.

Q. In regard to the working of convicts, if this help would not be sufficient to put the roads, or even a reasonable portion of the roads, in good repair, what have you to suggest for the remainder, after utilizing the convicts?—A. Well, I have already said that the mileage is so exceedingly great we can hardly hope to get a perfect system upon the entire mileage by any means that I know of. After availing ourselves of a composite system whereby we take advantage of those means that are produced without public aid, and the diminished distance that it will be necessary to haul after that system is perfected, as it is being, and the diminished necessary cost per mile, the addition of this labor is, as far as I am able to go, without recourse to taxation. Now, I think there should be three elements in that. I think that the locality where the road is built should contribute to its construction. For the last two generations the locality has borne the total cost. I guess nearly all the counties in Ohio, where they have had any improvement at all, have borne it in the immediate locality, not extending beyond the county limits and generally not beyond the township limits, and frequently not beyond the 1-mile or 2-mile limit. It has been a purely local matter. Where land is cheap, as it is getting to be now in most places, it can not bear the burden of building—that is, the entire cost of a stone road or any expensive road—so there must be some additional contribution. I think that the road itself should contribute to the extent of one-third of the cost, the State paying a third of the cost, and the United States Government a third of the cost.

Q. (By Senator KYLE.) You mean by the locality the county, do you?—A. No; I would leave that matter of locality to be determined by the judgment of those who live in the locality. If they think the county is the proper unit, let them contribute as a county; if they think the township is the proper unit, let them take that; if they think some temporary district is the proper thing, let them take that. In many of the laws passed in late years they have allowed two methods of initiation—one by the county commissioners by resolution, in which case they do it as the county; another, upon the application of petitioners, in which case the petitioners, or those for whom they stand, initiate the proceedings. If more than a majority on a certain road petition for it, then all those abutting upon the road have to pay. If they initiate in that way, then they do it with the understanding that they are to contribute a portion; if not, it falls to the county. In some cases it is divided again, 15 per cent paid by those abutting on the highway and the rest paid by those of a larger area. In my own county we raise \$100,000 taxes upon the entire property of the county, 80 per cent of which is in the city of Cleveland. Now, another thing about this raising of money. I have already referred to the fact that one-half of the population is found in cities and only half in the rural districts, whereas when the system was laid out, 2 or 3 generations ago, practically all the people lived in the country, and they bore the burden equally. Now, not only half the people are concentrated in the cities, but a good deal more than half of the wealth is concentrated there. In the State of New York 90 per cent of the taxable property is in the cities of the State and about 10 per cent only of the taxes is paid by those who live in the rural districts. If you still adhere to the old methods of making the locality bear the entire burden, you are undertaking to raise a sum of money that can not be raised. On the other hand, if you take in the county, or especially the whole State, as a taxing

district, you then get the property of the cities to contribute to the construction of the roads.

As I have said, in our county 80 per cent of the taxes is paid by the people living in the city of Cleveland; they do not object to it; they do not complain of it. In Preble County, Ohio, they have no great city. They have built many roads, and spent a good many hundred thousand dollars, and in Shelby County I believe more than \$2,000,000, without any great cities. In Hamilton County and Cuyahoga, where they have the largest population of any two places in the State of Ohio and the greatest wealth, they have built but few roads—almost none; none whatever in Cuyahoga County when they were building the road in Preble County. The time has come, though, when in these larger counties we are building roads, but we have adopted the system of taxing the entire property, including the city. We take the entire money, however, and spend it in the rural districts. Now, to even up on the matter of taxation, I claim it is equitable to do that, and it is necessary in order to raise the amount of money. So that with the prison labor, which is now a lost labor, devoted to this subject, and the distribution of the burden of taxation so as to have it rest upon all, we might raise a fund from which we could hope, in the course of 2 or 3 decades, to make a system which would give such means of transportation as would greatly lighten the burden of life, and would do away with at least some of the very great inequalities that are appearing in society. I have no doubt at all that the great fortunes made result very largely from the advantages that are naturally and properly taken of the increased means of transportation—the cheap means of transportation. Whenever you go to a community where they lack cheap means of transportation you invariably find that community does not have any very rich people; they are not able to amass a fortune; and when you go to those parts of the country where they have no means of transportation but animal power, they are universally and almost uniformly poor, almost poverty-stricken. We estimate the value of land by the distance that it is from cheap transportation. I believe that it is the high duty of government—State, national, and local—to turn its attention to this improvement, not only for the added value, but because it tends to place the people more nearly upon an equality as to the value of their property, the profits of their industry, and the rewards of their labor.

Q. (By Mr. A. L. HARRIS.) There is one question I would like to ask you, whether or not you have investigated the possibility of applying electricity to motive power on the common roads?—A. Well, yes; I have been for a good many years impressed with the idea that we must do something to overcome this very great inequality that I have referred to. In the first place I was surprised to find that it existed—being 50 times as costly to transport with the common method as with the cheaper method; and when I discovered that there had been but little improvement in two generations in animal power, my thought was to substitute some other power. And I was the first, I think, ever to suggest or at least to publish anything calling attention to the inequality that existed in this cost and to the possibility of making the substitution. I first thought that it might be universal, but whether that can be or not I do not think now that we are near enough to that period to contend for it; but I think the proper way is to work for a composite system, keeping them all along together, animal power and electric power and other inanimate power. Of course we have the steam car and the steamship; we have them highly developed to a remarkable degree, and I do not think there is any reason to complain of the results. Of course there is some inequality in the application, but I do not care to go into that now. The application of steam has proved to be wonderful in cheapening transportation by those two means, but in the other means and methods we have not made much progress, and we are now only just beginning to apply the other means. You ask as to electric power. That was the first power introduced that seemed to be applicable to help us out. I never thought it was the only power that we could rely upon, and I do not now think it is the best. It has been developed first and to the highest degree of perfection, but the trouble with electric power for our country use is that it takes too expensive a plant, and it takes a central power, it takes a trolley system, and the whole matter has got to be run as a great machine when you may have but comparatively little traffic to be passing at certain times. The great necessity is to have a vehicle that contains its own power, that can be run by the owner or attendant at his own pleasure, the same as he drives his wagon. Now, there is every reason to believe that different machines, propelled by different power from electricity, have already been developed to a sufficient degree to permit their introduction. The first great trouble was the excessive weight of these machines. If you will notice, they made them exceedingly heavy. There are some here now that weigh—well, they weigh 20 times, I guess, what they

carry—the net weight of one or two persons besides the driver that they carry; and the gross weight, well, it is so many times the necessary weight that I never have computed it. I repudiate all such schemes of helping us out with light transportation, because we must have a vehicle that does not weigh any more than it carries. As soon as you get a heavy vehicle you have got to make a heavy substructure to carry it, and when you get a heavy substructure, to make it durable, it runs up the cost so that it forbids the use on account of the necessary expense of it to the people.

Q. (By Senator KYLE.) When that day comes that you get the necessary vehicle, then, of course, the macadamized road is a necessity?—A. I do not limit myself to the macadamized road; I do not want to be understood as bound by that. I qualified my answer to that question as to whether I recommended it. I say that it is the best developed so far, but I believe we can very much improve upon that, both as to durability, as to the necessary power required, and as to the original cost. I think on all these things we can save, and yet, of course, I may be mistaken. That is the thing we are working out, but my information leads me to believe that there is a certainty of success in diminishing the cost, in making it more durable, and in diminishing the power required to run the vehicle. On all those lines I think we shall succeed.

Q. (By Mr. KENNEDY.) What effect is the introduction of these new road machines having upon the subject of good roads?—A. Well, you mean the new vehicles?

Q. Yes; I mean the new vehicles, the electric.—A. You do not mean road-working machines?

Q. No.—A. Oh, they are having a very powerful influence. I think. You see originally two generations ago, when the steam engine was first developed as a locomotive the thought was to move the ordinary small vehicles, only about three or four or maybe six in a train. They did not expect to make large vehicles. If you will look at the models in the museums or at the pictures in the galleries, you will find that the original plan was to take a large number of small vehicles that would carry perhaps six passengers, or a ton or two of freight, and make a train of that kind and put the steam engine on to draw several of them instead of having a power for each. They succeeded in developing the steam engine so as to draw heavier burdens than they thought they could, and then they made the carriages larger, and they have kept doing that right along up to the present time. That is really the embodiment of the entire evolution of transportation by steam cars; that is to say, two things—to increase the size of the vehicle and to increase the speed of the vehicle. That is the embodiment of everything that has been done; whatever else you see is subsidiary to that. Now, in consequence of their very great success, more than they supposed could be done, they dropped this original proposition of moving small vehicles, not because they could not do it, but because it was more profitable and more necessary and more beneficial to go ahead as they did, developing the high speed of the larger vehicles. That has been carried to such a point of perfection that it is marvelous beyond expectation. But the very thing that they started in to do two generations ago they are now taking up anew, and that brings me to your question about the effect that it has. The fact that they built these large vehicles, ran them so cheaply and so fast, made it undesirable to put the power of the nation or the State to improving the highways very much. It seemed to take the mind away from the idea of moving the small vehicles. But we still find that there is the necessity to use the small vehicle; the large vehicle going at a high rate of speed does not serve the people locally. It serves on the long haul both for freight and passengers, but for the short haul it is not suitable. You take a distance of from 5 to 10 miles and there is no cheap means of transportation existing to-day. Take the steam-car transportation. If you want to move anything 10 miles or 15 miles, when you take it with your horses to the car and load it and pay the high rate for the short haul and then unload it, the cost is just about equal to what it would be to haul the entire distance with animal power. We have not overcome that trouble, varying all the way from 5 to 25, and 30, and maybe 45 miles. Now, there is an unsolved problem there which can be brought out in these little vehicles that are now being introduced, and the effect of their introduction, about which you ask, is to stimulate everybody that has any connection at all with the matter, either as owners of property, producers of products, manufacturers of vehicles, or those engaged in the building of roads. Altogether they are working along the same line, and the prospect of very great results, beneficial to all classes, is much greater than it has ever been at any time.

Q. (By Senator KYLE.) I notice by this morning's mail that the League of American Wheelmen will make a demand both upon the Republican and Demo-

cratic conventions for a plank for good roads. That is the first time, I believe, it has assumed national importance?—A. Yes; that is true. I have communicated with a good many persons, and have in my office their suggestions as to what they would recommend to go in, and I am in favor myself of the national parties making some declaration. I do not think anyone yet can exactly formulate just where the line should be drawn. Of course, I have stated here generally that I thought it ought to be the three estates—that the General Government ought to do something, and the State ought to do something, and I think there is no doubt whatever, especially considering that they have this army of laborers that are looked upon now as a menace to free labor and to manufacturing, and whose labor is no benefit to the State in any way—I think the least they could do would be to contribute that.

Q. (By Mr. A. L. HARRIS.) The interest in good roads appears to be manifesting itself in different sections of the country, as I understand it?—A. Yes.

Q. Now, how is that being met, in the way of legislation, effectively? Is it by recommending commissions to investigate the matter in the different States where different conditions exist?—A. Yes; that is one of the most feasible ways. There has been and is yet a great prejudice in the minds of many people against the State or the nation taking up a matter that has heretofore been considered local; and it was properly considered a local question as long as animal power only could be used, because you can not go more than 8 or 10 miles and return with animals and draw loads as a general thing. So that it was proper enough to consider this as a local question as long as animal power was the only power. But with the new inventions, the substitution of inanimate power, the situation has changed economically and politically. The bicycle, which any person can own and use, is capable of going 100 miles a day, some more than that, and the automobile about the same way, and the suburban street cars going out 30 or 40 miles—have given us three new vehicles going upon the highway without animal power and for a long distance; so that changes the situation and in consequence of this change in economic facts and new inventions, I think it is a natural thing that there should be a change in sentiment. The Senator speaks about noticing the demand upon the parties; I also notice that the President of the United States, for the first time in two generations, in his last annual message to Congress brought this matter up; and also there was introduced by Senator Penrose a bill in the Senate, authorizing an appropriation of a large sum of money for this purpose. This idea which has prevailed so long—for two generations—to the effect that it was a local question, is still holding its course in the minds of many people, and they are not in favor of any declaration—not in favor of anything being done now to overcome that. I have been a little reluctant myself to go about it, and really I am pretty well satisfied that the best way we can do is to proceed by States, and that each State should have a commission. The State of Ohio had a temporary commission but it was not authorized to proceed to construct. The State of Massachusetts has a permanent commission; they are constructing and have been for 4 years or more, and I will give you some of the results. The State of Maryland has within the year appointed a commission, and they have made a very elaborate report; and I mention that they reported on the cost of transportation 26 cents a ton per mile. That is the latest report. I made the first one at 25, and in Mexico I got from the Mexican minister, 26. General Stone, my predecessor in office, made an estimate based upon inquiries in 1,200 different counties, at 25 cents; and the Maryland commission has brought in its report at 26 cents per ton per mile; so it seems to be verified—the very high cost that has been maintained.

Now, I believe, in answer to your question, that the best way we can do is to have the States take their own course about the matter, and where they are willing to do it to make their investigations. I have received within the last two or three days a letter from a Senator from Washington, through the Secretary of Agriculture to me, asking that we send an expert to that State to study the conditions there for 2 or 3 months and report to the local authorities what would be the best course for them to pursue. He says that they are willing to take the matter up, and their intention is to do something through the next coming legislature; but in order to get the best information that has been derived from the various sources he has written and requested that an expert be sent there to stay 3 months and to give them the results of the inspection of materials, and also what we may know about the best application of law and of finances, etc. I speak of that to show that there is an inquiry not only in regard to various initial points where most has been done by the leading States and at the office here by the Government, but where they have nothing at all they are asking for information. I went to Florida within a month on a very urgent request of members of Con-

gress and leading citizens interested in the improvement down there, and it seems that there is an inquiry pretty generally both North and South and East and West with a view of ascertaining what can be done to combine the elements economically, financially, and politically, and, of course, when I say politically I mean the power of the State and the Government, generally speaking. I feel very certain that the old idea of leaving all this matter to the political authority of a small locality, like a township or a district within a township, is a thing of the past. I believe the burden is too great and the difficulty too much to be overcome by the local authorities alone. I think they have done very well, the best that could be done in the past, but for the future it seems to me that they are not able to do it. Of course, they are not able to tax anybody but themselves, and when half the wealth and people have gone into certain centers, and when it has become a matter of general concern instead of local concern; when people with automobiles, locomobiles, bicycles, and all of these various means of locomotion want to go out a hundred miles or two, it is but just and necessary that they should contribute to the improvement of the highways. And we have no complaint whatever from any of the cities when we levy taxes for this purpose. I have never known of a complaint.

The most remarkable case that I know of is in our own county where, as I said, 80 per cent is paid by the city of Cleveland, and I have known of no complaint of that tax where it is so largely paid by the city, for they know that they need to go out about as much as the people outside need to come in. I look for a solution of this question along these lines and I am greatly encouraged. I hope that the Republican convention at Philadelphia will make us a favorable declaration. I do not urge them to make any very definite one, or to commit the Government to the old national road idea, but that they should look with some favor on this, and see that it is not only useful and beneficial, but that it would be just and equitable on this account; that they have all along for generations contributed millions and millions and millions of dollars to aid transportation on water by canal, by deepening harbors and rivers and the water communication between the Great Lakes, and then on the Western railroads they gave subsidies of lands and credit to aid in cheapening the transportation there. So that on the long haul, both over land and water, the Government has been very liberal, and I think, very wise. I have no complaint to make about it, but I do say that there has been a universal inequality on the part of the United States and on the part of the various States in reference to the improvements of the highways. We have fallen behind, and we are behind other countries. I do not think so much behind as some people make out, because in estimating the real advancement, I judge by all roads. I include all roads, the steam roads and the electric roads, and all that as forming a system which gives us a particularly cheap method after all. What we need is to supplement existing means and to overcome these very high rates that have remained high so long, and as a result I may say that we shall overcome a good many of the inequalities that have made the agricultural regions hard up as I think.

Q. (By Senator KYLE.) Is it not becoming common generally for street railroad companies to extend their lines far into the country?—A. Yes.

Q. Especially in almost all thickly populated counties?—A. Yes.

Q. Would it not be possible for farmers to utilize these tracks in some way under some system of franchise?—A. Yes. In 1891, in the pamphlet I referred to, I published a system showing how that could be done; how the farmer's products could be taken in on these tracks running through the country at any time and through the city only in the nighttime. Now, all the machinery of the street railroads in all the great cities after midnight is practically idle, and the streets are practically vacant. My recommendation at that time was that these roads be extended and that they be authorized and required to carry food products—that is, those perishable products that go to market from day to day—upon these cars. Let them be brought up to or near the city limits any time during the daytime and there held until say midnight, and then when the passenger traffic was over let these cars be taken through the streets of the city and to the various markets and commission houses and depots and wherever they might be stored, and the contents offered for sale the following day; the next night the cars to be returned empty and another set come in. Now that system, I hoped, would be introduced by public enterprise and aided the same as the canal system was, but I have given up that idea and I think the only way to do it is by private enterprise and that the public part of it shall be confined to these tributary roads, as I said, where the short haul would only have to be projected for 2½ to 5 miles. That will so diminish the wagon haul that I believe it would be possible to make a system that will accommodate the people.

Q. You might cause the street car companies to haul nonperishable products and all that just as well, so that the company would furnish the cars and all the farmer would have to do would be to furnish a sidetrack at his own farm?—A. Yes; I have no objection to that. I have only stated what I recommended as a very necessary thing, because the perishable products must get to the markets. They have to go there in some way. Many people object to carrying on the street car these perishable products that are marketed and transported to different places. I have no objection to it myself; I think it is desirable and probably will be found to be necessary; and the vehicle which I spoke to you about, of which I have a model, carrying twenty times its own weight, is produced with reference to that very service. I hope to be able to offer that by the time the Buffalo exposition comes off next year; I hope to be able to have models of that to show at that exposition what can be done in that way.

Q. The question occurs to me from the fact that these franchises are being given away by the farmers of all the counties in all the States in every year, without reserving any privileges for themselves, as far as I have discovered, except the privilege of paying their fare the same as anybody else.—A. I think that is the universal case with the exception of Ohio. I foresaw this at least six years ago, and being a member of the legislature I had a law passed in the State of Ohio that authorized the use of all such tracks for such a purpose, and also requires every existing street railroad company in the State to pass these cars with their contents and all products and passengers and everything that is produced in the country, over the city road upon the best terms and conditions that they shall secure for themselves.

Q. And that is the law they operate under now, by which the farmers send their milk cans into the city, is it not?—A. Yes; there was some objection. The people who gave these rights of way originally treated the street car as a personal service to take the place of the carriage, and it was natural and proper and just enough at that time for the owners—that is, a majority of the owners of the property on a city street—to decide whether they desired that conveyance; but when we now want to go further out and substitute these new means for the old superannuated means, it is another question to some extent, and I hold that the owners of abutting property ought not to be authorized or empowered to forbid the use of the street for the general purpose intended by this use, in our cities and through the country. I think it has succeeded pretty well in the city of Cleveland; but in Cincinnati—I think they have got them by the throat down there. They are carrying passengers in the city of Cleveland farther than any other place in the world for a small sum. They are carrying about 16 or 17 miles for a single fare on a transfer, and on the straight haul about 9 miles.

Q. (By Mr. A. L. HARRIS.) What State has the best road laws?—A. That depends. I think the State of Ohio has had the best road law for the past in producing roads with reference to the local idea. I believe we have had the best there was; but with the new idea based upon the changed conditions of population and wealth and longer distances to be covered, I do not believe our laws are so suitable now as some others. I think New Jersey may have. That is a small State, and they have a law that divides the cost of the improvement between the State and the locality, and they seem to be very well pleased with it and are producing wonderful results. The State of New York has lately passed a similar law. The State of Massachusetts, however, is the only State that has a law requiring the entire State to bear the burden of improvement. I believe even in their case that a proportion of the grades is made by the locality. If they desire to reduce the grades I think the locality bears that, but the improvement is borne entirely by the State. It is the old idea of the State road that they once had in Ohio. You know we have some State roads in Ohio, but there is nothing left of them but the name. There was a time when the State had jurisdiction and the plan was to build and maintain those roads for public purposes with the State's money.

Q. (By Mr. FARQUHAR.) Has not New Jersey the best roads of any State in the United States?—A. I do not think they have. They have the best talk on the road question because they were the first State to revive road building. In the State of Ohio, before you ever heard of any roads in New Jersey, we had built up a system far superior, and a single county in the State of Ohio—that is, Shelby County—had spent more money before ever you heard of any roads in New Jersey than they have ever spent in New Jersey. Under the new system of State aid New Jersey has probably done most, and I say in reply to your question that it is possible for present conditions and the conditions we are entering upon now that their plan is the best. It has been talked up very generally and imitated by your State to quite an extent. A good many people do not know, and perhaps you did not, that we have better roads and more of them than they have in all these States—I

will put in New York and Massachusetts and New Jersey altogether. They are the only three States that have done anything. Put them all together and they have not done much about it yet. It is an old thing and we do not say much about it in Ohio.

Q. Is it not generally talked that New Jersey has the best roads? Have you not found that that is the general idea outside of that State? Now, you take from Philadelphia to New York; you can get a road there for the finest carriages and teams, a clear, level road, as smooth as a billiard table, as the expression is down there. Now, do we have any such roads in New York and Ohio?—A. We have roads being built in Ohio just as good, and we have had them right along. New Jersey being a small State, they are able to put them through the whole State; but our State being a large State, we have done it by counties, and we have done more in one county than they have in the entire State. We have put our roads a mile apart, thinking that the population would be equally distributed, and one part was entitled to have as much as any other, but with concentration of population and wealth it has become necessary to make the through roads. I will say that on the whole the system as they have it in New Jersey is the best. Nature has done a good deal to make New Jersey level.

Q. Do you think the law providing for roadmaking is a better law than the State of Ohio has?—A. I believe I have stated that for the future I am willing to concede that.

Q. (By Mr. A. L. HARRIS.) In the event that we recommend something, we want the best State law that we can recommend to the legislatures of the different States?—A. Well, the New Jersey State aid law is the first of the State aid laws since the revival of road building, and it is considered to be the leading law and has been pretty generally imitated; but it is claimed that the law of New York State is a little bit of an improvement on that—substantially the same thing; but it is claimed that they have amended it in a small way so as to make it a little more applicable. It is virtually the same thing with some slight amendments, what they call the Higbee-Armstrong law, drawn, I believe, by Mr. John A. C. Wright, of Rochester, proposed two or three times before it was finally passed, and is claimed to be the best. But let me say in that State also they have passed a constitutional amendment that forbids the use of prison labor in the ordinary way for manufacturing commercial articles, and they are in such shape that I believe they have got to back up their law on prison labor, and they may become the first State in road building as they are in population and wealth.

Q. Was the Ohio law, in the days when they were building pikes so generally, applicable to all portions of the State alike?—A. Oh, no; in northern Ohio we have never built any under it at all.

Q. Did they in the southeastern part of the State?—A. No. It was suitable for a fertile, homogeneous territory.

Q. (By Mr. KENNEDY.) What do you think of the oyster-shell roads around Baltimore?—A. They are nice, but not very durable.

Q. (By Mr. FARQUHAR.) Have you noticed lately a report from one of the trade papers of London that there is a great trucking company in London that is using automobiles, and that they use 50 of these automobiles, and they reported that they have saved in 12 months in the difference of horses, feed, men, etc., 21 per cent?—A. I did not notice that, but I can well believe that it is probable and attainable. We are going to make rapid changes. I just feel it.

Q. (By Mr. KENNEDY.) I thought perhaps the oyster-shell roads were finer than anything you had in Ohio or in New York.—A. They are very nice, indeed, but they are not sufficiently hard to be durable under heavy traffic. They have to be replaced. They are very nice.

Q. (By Mr. A. L. HARRIS.) Have you any general statement, Mr. Dodge, that you desire to make that you have neglected that would be in the interest of the cause of good roads?—A. I think I have covered mainly the general thought that I had in mind. Of course the question touches almost every industry, and I would like to make this statement: that population, like everything else, moves along the line of least resistance, and the better roads form lines of less resistances than poor roads, and on that account where you find the better roads and better methods there you will find the greater numbers of population, and where these greater numbers are there the greater wealth will be, and the power of labor itself is increased by better modes of transportation. There is a general increase not only in the power of production, but in the value of land, and it has a more powerful influence on the location of the people than almost anything else.

Mr. KENNEDY. I should like to suggest that Mr. Dodge be invited to select what he considers the best State law in regard to roads, and make such additions and amendments to it as he thinks proper, and submit it to the commission for their consideration.

The WITNESS. I would be very glad to do that.

(Subsequently, viz, July 24, 1900, Mr. Dodge, in a letter to the secretary of the commission, said: "I send you copy of the Higbie-Armstrong act as passed by the legislature of New York March 24, 1898, which I recommend as the most suitable State aid law yet passed by any State." A copy of the law referred to follows:)

AN ACT to provide for the improvement of the public highways.

Became a law March 24, 1898, with the approval of the governor. Passed, three-fifths being present.

The people of the State of New York, represented in senate and assembly, do enact as follows:

SECTION 1. The board of supervisors in any county of the State may, and, upon presentation of a petition as provided in section two hereof, must pass a resolution that public interest demands the improvement of any public highway or section thereof situate within such county, and described in such resolution, but such description shall not include any portion of a highway within the boundaries of any city or incorporated village, and within ten days after the passage of such a resolution shall transmit a certified copy thereof to the State engineer and surveyor.

SEC. 2. The owners of a majority of the lineal feet fronting on any such public highway or section thereof in any county of the State may present to the board of supervisors of such county a petition setting forth that the petitioners are such owners and that they desire that such highway or section thereof be improved under the provisions of this act.

SEC. 3. Such State engineer, upon receipt of such a resolution, shall investigate and determine whether the highway or section thereof sought to be improved is of sufficient public importance to come within the purposes of this act, taking into account the use, location, and value of such highway or section thereof for the purposes of common traffic and travel, and after such investigation shall certify his approval or disapproval of such resolution. If he shall disapprove such resolution, he shall certify his reasons therefor to such board of supervisors.

SEC. 4. If he shall approve such resolution, such State engineer shall cause the highway or section thereof therein described to be mapped, both in outline and profile. He shall indicate how much of such highway or section thereof may be improved by deviation from the existing lines whenever it shall be deemed of advantage to obtain a shorter or more direct road without lessening its usefulness, or wherever such deviation is of advantage by reason of lessened gradients. He shall also cause plans and specifications of such highway or section thereof to be thus improved to be made for telford, macadam, or gravel roadway or other suitable construction, taking into consideration climate, soil, and material to be had in the vicinity thereof and the extent and nature of the traffic likely to be upon such highway, specifying in his judgment the kind of road a wise economy demands. The improved or permanent roadway of all highways so improved shall not be less than eight feet nor more than sixteen feet in width unless for special reasons, to be stated by such State engineer, it is required that it shall be of greater width. He shall, if requested by the resolution, include provision for steel plate or other flat-rail construction in double track.

SEC. 5. Upon the completion of such maps, plans, and specifications such State engineer shall cause an estimate to be made of the cost of construction of the same and transmit the same to the board of supervisors from which such resolution proceeded, together with a certified copy of such maps, plans, and specifications, and of his certificate of the approval of the highway or section thereof so designated as aforesaid.

SEC. 6. After the receipt thereof, upon a majority vote of such board of supervisors, it may adopt a resolution that such highway or section thereof so approved shall be constructed under the provisions of this act, or of any existing act, and thereupon shall transmit a certified copy of such resolution to such State engineer.

SEC. 7. In case the boundaries of such proposed highway shall deviate from the existing highway, the board of supervisors must make provision for securing the requisite right of way prior to the actual commencement of the work of improvement.

SEC. 8. Upon receipt of the certified copy of the resolution provided in section six, such State engineer shall advertise for bids for two successive weeks in a newspaper published at the county seat of such county, and in such other newspaper as shall be deemed of advantage for the construction of such highway or

section thereof, according to such plans and specifications, and award such contract to the lowest responsible bidder, except that he may in his discretion award the contract to the board of supervisors of the county or the town board or boards of the town or towns in which such highway lies, and except that no contract shall be awarded at a greater sum than the estimate provided in section five. But if no bid otherwise acceptable be made within such estimate, such State engineer may amend his estimate, certify the same to the board of supervisors, and upon the adoption by it of a resolution as provided in section six based on such amended estimate, proceed anew to obtain bids and award the contract as herein provided. Such engineer may reject any or all bids, and before entering into any contract for such construction he shall require a bond with sufficient sureties, conditioned that if the proposal shall be accepted the party thereto will perform the work upon the terms proposed and within the time prescribed and in accordance with the plans and specifications; and as a bond of indemnity against any direct or indirect damages that shall be suffered or claimed during the construction of such road and until the same is accepted. The people of the State of New York shall in no case be liable for any damages suffered. Partial payments may be provided for in the contract, and paid in the manner herein provided when certified to by such State engineer to an amount not to exceed seventy-five per centum of the value of the work done; twenty-five per centum of the contract price shall be retained until the entire work has been accepted. Whenever a county engineer has been appointed in the county in which such highway or section thereof is to be constructed, he shall have general charge and supervision of the work under the direction of such State engineer and shall report to him from time to time the progress of the work and such facts in relation thereto as may be required. If there is no county engineer, such State engineer shall have some competent person to superintend and have engineering supervision of the work.

SEC. 9. One-half of the expense of the construction thereof shall be paid by the State treasurer upon the warrant of the comptroller, issued upon the requisition of such engineer, out of any specific appropriations made to carry out the provisions of this act. And one-half of the expense thereof shall be a county charge in the first instance, and the same shall be paid by the county treasurer of the county in which such highway or section thereof is, upon the requisition of such engineer; but the amount so paid shall be apportioned by the board of supervisors, so that if the same has been built upon a resolution of said board without petition thirty-five per centum of the cost of construction shall be a general county charge and fifteen per centum shall be a charge upon the town in which the improved highway or section thereof is located, and if the same has been built upon a resolution of said board after petition as provided in section two thirty-five per centum shall be a general county charge and fifteen per centum shall be assessed upon and paid by the owners of the lands benefited in the proportion of the benefits accruing to said owners as determined by the town assessors in the next section hereof.

SEC. 10. The town assessors of any town in which any highway or section thereof has been improved or constructed pursuant to petition as provided in section two of this act shall have power and it shall be their duty, upon receiving notice from the board of supervisors of the county in which said town is located of the cost of construction or improvement of such highway or section thereof in such town, to assess an amount equal to fifteen per centum of said total cost upon the lands fronting or abutting on such highway or section thereof. Such assessment shall be apportioned according to the benefits accruing to the owners of the lands so located, according to the best judgment of said assessors, and the assessments so made when duly attested by the oaths of such assessors shall be collected in the same manner as the general taxes of such town are collected.

SEC. 11. The construction and improvement of highways and sections thereof under the provisions of this act shall be taken up and carried forward in the order in which they are finally designated, as determined by the date of the receipt in each case of the certified copy of the resolution provided in section six by such engineer as hereinbefore provided.

SEC. 12. Upon the completion of such highways or sections thereof so constructed by such engineer, and his acceptance of the same, and after payment has been made as herein provided, such engineer shall inform the board of supervisors of such county that the highways or sections thereof designated have been constructed as herein provided and his duties in regard to the same are finished; and he may serve notice on said board to accept such highway thus constructed, which notice shall be filed in the office of the clerk of said county; and twenty days after the service and filing of said notice such highway or section thereof

shall be deemed accepted by said board of supervisors of such county, and thereafter they shall maintain the same as a county road and apportion the expense as they may be empowered by law.

SEC. 13. All persons owning property abutting on such road so improved, or residing thereon, shall thereafter pay all highway taxes assessed against them in money, in the manner now provided by law.

SEC. 14. Whenever any county has had aid in building any such highway and it seems advantageous to such State engineer that a section or sections of highway, not exceeding one mile in length, should be constructed under this act to connect these roads together, and would be of great public utility and general convenience, he may serve notice on the board of supervisors of such county, and shall file one in the county clerk's office, designating the highways already constructed and the existing termini and the section or sections, in his opinion, necessary to be constructed, and his reasons therefor. And it shall be the duty of the board of supervisors to provide for the construction of such connecting highway or section thereof within one year after the service and filing of such notice under this act.

SEC. 15. In addition to his other powers and duties, the State engineer and surveyor shall compile statistics relative to the public highways throughout the State, and shall collect all information in regard thereto deemed expedient. He shall investigate and determine upon various methods of road construction adapted to different sections of the State and as to the best methods of construction and maintenance of roads and bridges, and such other information relating thereto as he shall deem appropriate. He may be consulted at all reasonable times by county, city, town, or village officers having care and authority over highways and bridges, and shall advise such officers relative to the construction, repair, alteration, or maintenance of the same, and shall furnish such other information and advice as may be requested by persons interested in the construction and maintenance of public highways and shall at all times lend his aid in promoting highway improvement throughout the State. He shall hold in each year at least one public meeting in each county and shall cause due notice of such meeting to be given. He shall cooperate with all highway officers and shall assist county and town authorities and when requested by them furnish them with plans and directions for the improvement of the public highways and bridges.

SEC. 16. He shall report annually to the legislature concerning all the work performed by him, together with such recommendations upon the subject of highway construction and maintenance as to him shall seem appropriate.

SEC. 17. The commissioners of highways and town board of any town, and the board of supervisors of any county, and all other officers who now have or may hereafter have by law the care and supervision of the public highways and bridges, shall from time to time, upon his written request, furnish him with all available information in connection with the building and maintenance of the public highways and bridges in their respective localities.

SEC. 18. The operation of this act shall not be affected by any special act, but the highways may be improved under this act or such special act wherever the same may now exist.

SEC. 19. This act shall take effect immediately.

(Testimony closed.)

WASHINGTON, D. C., January 15, 1901.

TESTIMONY OF MR. MICHAEL P. MORAN,

President National Grain Growers' Cooperative Association.

The Commission met at 10.55 a. m., Senator Kyle presiding. At that time Mr. Michael P. Moran appeared as a witness, and, being first duly sworn, testified as follows:

Q. (By Senator KYLE.) Please give your name, post-office address, and vocation.—A. My name is Michael P. Moran, of Graceville, Minn. My occupation is and has been that of a farmer for 40 years.

Q. You are summoned for the purpose of giving testimony upon agricultural topics in general, and more particularly, perhaps, on the question of grain production and farming in the Northwest. You may proceed in your own way and state to the Commission your views upon the subject.—A. I have prepared for you a few papers upon the topics of agriculture which will be interesting at least to the

farmer. One of these papers is as to the cost of raising wheat for a given period of years; another is as to the price of wheat for a number of years; another on transportation and elevators and combines and the result to the farmers; also a paper on text-books that our people believe ought to be introduced into the school for the education of the youth; also one upon the Nicaragua Canal and its effect on farmers and the sale of wheat. Knowing how valuable your time is, I will either read all these or submit them without reading them, and then answer each and all questions that are put to me to the best of my knowledge and belief.

Q. You would probably better proceed in your own way, taking the subjects seriatim as you suggest them, and either state them orally to the Commission or read them as you have them prepared. We can ask questions from time to time to make matters more clear, if necessary.—A. (Reading):

Cost of wheat raising.

Average cost for 11 years of raising an acre of wheat per year in Bigstone County, Minn.

Plowing stubbles	per acre ..	\$1.00
Dragging	do15
Drilling or seeding	do30
Cutting or binding, including twine	do75
Shocking	do15
Stacking	do	1.00
Threshing	do60
Hauling to market from 3 to 7 miles, per bushel03
Interest on land, worth \$20, at 7 per cent per annum		1.40
Tax, including road tax30
Seed, 1½ bushels, at 60 cents75
Total		6.43

Average yield per acre for 11 years	bushels ..	10
Average price for No. 1 Northern for 11 years	per bushel ..	.60½

There is usually 2 cents per bushel difference between No. 1 and No. 2, and the same difference between No. 2 and No. 3. This would make an average per bushel of \$0.58½. There are still lower grades and correspondingly lower prices, such as "rejected" and "no grade."

No. 1 Northern wheat averaged the following prices for the month of October for each of the past 11 years at the local markets of Graceville:

	Per bushel.		Per bushel
October, 1890	\$0.76	October, 1896	\$0.55
October, 189184	October, 189772
October, 189256	October, 189853
October, 189352	October, 189955
October, 189449	October, 190065
October, 189544		

Q. (By Mr. FARQUHAR.) How do you account for the small price per bushel from 1892 to 1896?—A. The climate has a good deal to do with it.

Q. The successive seasons for 3 years?—A. Yes. For instance, last year was extraordinarily dry and had the effect of producing a very small crop. In 1895 we had the largest crop we have ever had there, for the season seemed to be very favorable, and hence the large crop that we secured. (Continuing reading):

Average number of bushels of wheat raised per acre each year in Bigstone County, Minn., for the past 11 years.

	Bushels.		Bushels.
1890	11	1897	10
1891	12	1898	8
1892	7	1899	8
1893	6	1900	6
1894	10		
1895	24	Total	110
1896	8	Average	10

Q. (By Mr. A. L. HARRIS.) Is yours an average county?—A. Yes; I would judge our county is about an average of several counties around there.

Q. These figures are the average for your county?—A. I give them for Bigstone County, though I think the figures would apply to the adjoining counties also.

Q. (By Senator KYLE.) State the geographical location of your county.—A. The city of Ortonville is about 190 miles almost directly west and a little north of St. Paul.

Q. You adjoin Dakota at Bigstone Lake?—A. Yes.

Q. (By Mr. FARQUHAR.) Is that yield of an average of from 8 to 12 bushels the result of continual cropping of the same land?—A. Yes; continual cropping of the same land.

Q. You use no artificial fertilizer, compost, or anything of that kind?—A. Not so far; we have not used any. We consider our land fertile enough so far.

Q. What is the character of your soil?—A. Dark loam.

Q. (By Senator KYLE.) How do those figures compare with those of the previous 10 years?—A. They were pretty near the same; there is very little difference. I think these figures would compare very well with those of the previous 10 years.

Q. I wish to bring out whether there is any falling off in the average for 10 years from the breaking of the virgin soil.—A. After the breaking of the virgin soil in our country the crops appear to be very low the first year, as compared with the second, and the second, as compared with the third, but from the third crop they are fair. They have been a pretty fair average with the exception of particularly good years, such as 1895, which gave us a larger yield.

Q. (By Mr. FARQUHAR.) Is it profitable farming at 10 bushels an acre at your average price for the last 10 years?—A. No; the more wheat we grow the poorer we get. We call ourselves getting richer by the increase in the value of our lands as other people settle in around us. That increases the value of our land, and as their children grow up their parents begin to buy up adjoining land and settle their children thereon; so the land increases in value.

Q. (By Mr. LITCHMAN.) Has there been any attempt to diversify crops?—A. Yes; we are beginning to diversify crops there lately. We are compelled to do so for the reason that the wheat does not pay. In former years wheat averaged a better price, and thus we got a better living from it; but as years pass by wheat seems to depreciate in value, and hence we are beginning to diversify our farming, seeding down with timothy and clover, raising more stock, and putting out the manure on the land, and raising a little more corn than we used to raise. In former years we were under the impression that in that part of the country corn could not be produced, but we found we were in error and that we can raise a very fair crop of corn there.

Q. With wheat 59½ cents a bushel on the farm, what would be the probable quotation at Minneapolis?—A. There is usually a difference of 10 cents a bushel between the price paid in Graceville and the price paid in Minneapolis; that is for freight rates, elevator charges, commissions, etc. Now may I read another paper? (Reading:)

The free text-book.

As one of the most practical means of distributing the most practical and universal knowledge of farming, I would advocate the compulsory use of a text-book on practical farming.

I would advocate that the General Government should ask specialists to prepare a brief article on every subject connected with farming, commencing by showing the pupil the importance and extent of the industry of agriculture as the greatest thing in the world, etc.; how honorable it is; how near it is to God and nature; how important it is to understand the mysteries of nature and apply them with intelligence; to learn the character of the plant he sows, its roots, its composition, its seasons, climatic conditions, etc. I would have each chapter deal with some element of intelligence in farming, such as manure, fertility, diversity of crops, vegetable and animal industry, statistics of crops raised, prices, markets, exports, and features of this kind, which would be so arranged with illustrations that the pupil would be able to fix these thoughts well in his mind and use them in after life with intelligence and advantage to himself and the industry of agriculture.

I would ask that this text-book should be furnished through the General Government, under the direction of the Department of Agriculture, to be used in the country and village district schools and in as many town and city schools and colleges and universities as possible.

I would also advocate a more generous government aid to State agricultural colleges and experimental stations, that their usefulness might be extended and those institutions improved.

My views are that the tendency is, when the boy arrives at the age of maturity, to depart from the farm and seek employment in the city. There is nothing in our school text books that would show to the farmer's boy the nobility of his calling and the greatness of the enterprise that his father is engaged in; that the agricultural industry is the greatest of all industries in our country, and that there are fully one-half of the people of the United States engaged either directly or indirectly in agriculture, producing the enormous amount of \$4,000,000,000 of wealth per annum. Yet, alas! the farmer's boy, instead of being proud of his occupation seeks to throw off the yoke, as he calls it, and take himself to the city to enjoy, as he calls it, city life, and get away from the drudgery of the farm. I must confess it is a great inducement for them to get away from the farm, for the hours are long and tedious, working from early dawn to dark at night, and often into the late hours of the night for a very small remuneration. He is deprived on the farm of good clothing, of reasonable hours for leisure or pleasure, and has to be deprived of school to work on the farm during the busy times of seeding and harvest.

Q. (By Mr. A. L. HARRIS.) Do you belong to any organization that advocates a change in the school system in your State?—A. Yes: I have the honor to belong to the Grain Growers' Association, composed entirely of wheat growers, and I have also the honor to be their president. We have them scattered in the wheat belt very extensively. We also encourage through this organization the erection of farmers' cooperative grain warehouses. We have a number of these already in existence. We held a convention in Fargo a year ago last winter, and we had a great gathering there. The opera house was filled from cellar to garret. We had very prominent men there to lecture to the farmers, among them was Mr. James J. Hill, president of the Great Northern Railroad, and he delivered a very instructive lecture to the farmers. I must state here that in former years the farmer looked upon Mr. Hill as one of his worst enemies; now, from his meeting with them at these public meetings and talking to them, the farmers seem to have changed their views to a great extent, and they look upon Mr. Hill to-day as the friend of the farmer.

Q. (By Senator KYLE.) For the record, state what is his official capacity.—A. He is president of the Great Northern Railroad.

Q. And of the Northern Pacific also?—A. I do not know about that.

Q. (By Mr. A. L. HARRIS.) Has the course of study that you suggest been introduced into your schools?—A. It has not been introduced so far. Strange to say, in our country schools farming is scarcely mentioned. There is nothing in the schoolbooks to encourage a boy and to show him that he is a member of the great agricultural class, and hence there is nothing to stimulate him or train his mind to look on the occupation of his father as being honorable, just, and above suspicion.

Q. (By Senator KYLE.) You speak of the tendency of young men to leave the farm when they come to their majority; is that tendency increasing, do you think?—A. It is increasing; I am sorry to have to publicly announce that it is increasing.

Q. In your opinion, do they better their condition by leaving the farm?—A. In my opinion they do not. In my opinion they make matters worse. They seem to forget their training when they go to the cities, and fail to make for themselves a home, as they would have made if they had stopped on the farm. No matter how humble and degraded we are as farmers, we look with pride upon our home (though unfortunately very often we have a mortgage on it; I am sorry to have to confess that, but still we are in hopes of wiping that mortgage off) and we are ready to defend it with our lives.

Q. Now, you say if they had remained at home they would have acquired a home?—A. Yes.

Q. Whereas by going to the city they have failed to acquire a home?—A. Yes.

Q. Do you think it is possible for the farmer's son to acquire a home by remaining on the farm?—A. Yes; for the reason that when the father dies he can not carry the soil away with him and naturally it must belong to somebody, and he will leave it to his son if he has but one, or divide it up among them if he has more than one.

Q. I wished to bring out whether the opportunities of the young man to acquire his home are as great as they were 25 or 30 years ago?—A. I do not know that the opportunities are as good. For my humble self, I thank my country for having a home. I never owned a foot of land until my Government gave me a homestead; and I own that yet and will leave that to my family; so there is a chance for the young man if he remains on the farm.

Q. I am not speaking particularly of the homestead. Suppose he has to buy his

is mostly logs, lumber; and minerals. Some common cattle are driven from these divisions and find a market in the blue-grass section.

Q. Have you any mining interests in your State?—A. Considerable; yes, both in the western section and in the eastern.

Q. Coal?—A. Coal mining, and some iron mining—principally coal, though.

Q. (By Mr. PHILLIPS.) Any petroleum?—A. Yes; there is some very profitable development in petroleum in those mountain regions.

Q. In what section is that—the western part or the eastern part of the State?—A. I might say in the southern part. And there is one field—about the best field we have—in Wayne, Cumberland, and Barren counties, along the Cumberland River. There is also a large field developed in the eastern part of the State, next to West Virginia.

Q. (By Mr. A. L. HARRIS.) Do you diversify your agricultural industry in Kentucky?—A. We do, to a very great extent. We grow corn, wheat, tobacco, hemp, barley, rye, oats, blue grass, orchard grass, timothy, and corn, and around our cities we have quite a section given over to potato growing. We revolutionized the seed-potato business there. About 20 years ago, when I was agricultural editor—a young agricultural editor—I heard of a system in vogue near our city that was new to me, and no one else had ever heard of it, and it never had been written up. I got into a buggy and went out to investigate it, and I found a couple of Germans there growing potatoes. They could beat everybody. Their potatoes were superior in appearance; they were 10 days or 2 weeks earlier; there was a different growth of vine, and yet they were the same variety that was well known then, one of those early varieties, the "Early Rose." I investigated their method and found that they were planting the immature seed instead of the mature seed. They would dig up part of their potatoes—the Early Rose would ripen with us in July—and expose them to the sun for a while and then put them in a shady place, and then take them and cut them up and plant them again right in midsummer, say the 1st of August. By the time the frost would come the tubers would be about one-third grown, and the frost would kill the vines. They would then take them up, and the next spring they would cut them up and plant them again. No one else did that. These Germans would always be in the market and ship north 10 days earlier than any other growers. I could not account for their success in any other way except that the potato is not a seed. The seeds of a potato are grown in the ball on top of the plant. The potato itself is not the seed; it is a tuber, an enlarged root only. The only theory by which I could go (then there had been no scientific investigation) was that when the seed formed the root itself was ready to go into decay, and therefore if you kept that from July on to the next spring there was so much decadence that it was not as vigorous as the root would be if taken up and planted again and perpetuated without making the seed. That was the only theory there seemed to be about it, and I advanced that theory and had a great deal of discussion about it; but I predicted then that whilst thousands of barrels of potatoes were shipped in from western New York and Michigan to our section the discovery would revolutionize the business, and that seed potatoes would go the other way. This prediction I lived to see verified. For a great many years they have grown seed potatoes and shipped them to the North, and they never let them get over one-third of their growth. Now, if you plant a whole potato of this second growth there will only one shoot come from it. If you plant a matured potato where the vine has been allowed to mature, a bunch of plants will come up. The vines of second growth will come up as thick as your finger in rich land, and will produce from 5 to 8 tubers instead of 8 to a dozen, and of the 5 or 8 nearly every one will be merchantable. They are smoother, rounder, and some 10 days earlier. The discovery revolutionized our potato growing there, and made Jefferson County a very large potato-growing county. The seed goes North thence instead of coming South. All around our cities they grow a good many potatoes. They all used this second-crop seed. The only change they have made in the method is that now they take the potatoes up in July and hold them in cold storage until the next year to plant for second crop instead of planting the tubers of the same year.

Q. To what extent is your State interested in raising blooded stock?—A. Kentucky has always been celebrated for its stock. For many years we held the record for the fastest horses, the best whisky, and the most tobacco.

Q. Do you include cattle?—A. Cattle. We had the largest herds of cattle, but in later years we have been outdistanced by the West. We are, however, keeping up our interests and still have some of the finest Shorthorns, Jerseys, Herefords, Polled-Angus, and Holsteins. Kentucky is the headquarters for a breed of horses that we are establishing—an American breed. General Castleman and many Kentucky, Missouri, and Illinois breeders have been interested in it for the

last 10 years—the American saddle horse. We have got it to the front, and we are largely sustained by Missouri and Illinois, and nearly all the States have taken them and have herds of them. It is a resurrection of the old blue-grass saddle horse that was famous in the 40's and 50's. You could get on his back and go with perfect ease anywhere. During the trotting fever this horse almost disappeared from sight. We picked up the remnants of the breed and brought them together. We have now nearly 4,000 of them registered and are breeding now along certain lines to perpetuate that old Denmark strain in others.

Q. Is that interest confined to any particular section of your State?—A. No; it is all over it, except in the mountainous region.

Q. (By Mr. CLARKE.) Please describe that horse.—A. I wish I had some photographs of him. One passed through here yesterday that it would have done you good to see. He came on the same train I did, by express. General Castleman shipped him to New York to be sold there; and there were several others; a carload of them went through. They are very stylish; they range up to 15½ or 16 "hands" in height; they have long slender necks; are usually of bay or brown or other deep rich color; the tail sets high; their limbs are clean; they have sloping shoulders and short backs, and are well ribbed. They are active, but not what you would call fast horses. They can rack along at a 3-minute gait—a good one; but they have a slower pace, the running walk, which we think is the best gait.

Q. Are they light steppers?—A. Light steppers; yes. They are nimble footed; do not move you in the saddle. I see a man go through town often on one of those horses at what we call the running walk, similar to the fox trot. He will go at a gait of 6 miles an hour, which can be increased to 7 or 8, and the man sitting in the saddle will go upon a perfect line. The horse's back does not bring him up and down at all; he moves horizontally.

Q. (By Mr. A. L. HARRIS.) Is that what is called racking?—A. No; the gait is not a rack. A rack is pretty much the same easy gait to the rider, but it is a little harder on the horse. We call a horse of that kind a single-footer. It is not such a good gait for a long distance, but it is nice to see. They do not like a rack in the East, because they want a jolter there; they want a horse that trots. Our horse also has a good square trot.

Q. (By Mr. CLARKE.) Are these horses trained for galloping?—A. Oh, yes; there are 5 gaits—the rack, the running walk or fox trot, the slow pace, the canter, and the square trot. The slow pace is not much used; it is somewhat of a gait on a good level road, but it is not much encouraged. We want the running walk, and the square trot, and the canter.

Q. Are they so well trained there that by signal they will change from one gait to another?—A. Yes; the American saddle horse is quite intelligent, and they soon pick up those signs; and you can snap your finger or, according to the way you train them, press on the neck, and they will change the gait.

Q. Is there a Morgan or a Hambletonian strain in them?—A. There is a Morgan strain introduced from 2 or 3 sources; one through Blood's Blackhawk—that is from the old Green Mountain Blackhawk. We got that strain through Cabell's Lexington, which is a pure Morgan horse, with Blackhawk strain. But the real foundation of the American saddle horse is the thoroughbred by selection.

Q. That is English?—A. That is the English race horse; yes. The foundation in that line is the old horse Denmark, which was a 4-mile race horse. He had size, substance, and quality; all those things necessary. His progeny seems largely to have come through one of the sons, Gaine's Denmark—that is, the saddle qualities—and it is worth thousands and thousands of dollars to our State. Now, this strain of horses is being taken in the Eastern States more than they ever were. Ten years ago there was scarcely one used there at all, but we made an exhibition of them at the World's Fair, and from that time they have been in demand all over the country. Some of them have been exported. Missouri has taken a leading part in the development of this horse, and Illinois stands scarcely second. Probably the greatest show horse in existence for style and beauty is one of these American saddle horses, known as Chester Dare. He seems to put his head right up in the clouds. Among them are also many other great show horses.

Q. Have you found that the admixture with the Morgan and Blackhawk strain has been a great improvement over the original thoroughbred?—A. Yes. I think its tendency is to give more substance and lasting quality. The mixture has proved very wise and profitable.

Q. (By Mr. KENNEDY.) Do you get fancy prices for these horses?—A. Yes. They sell for—I am speaking of good specimens—from \$500 to \$3,000. It requires so much less to develop and train one than it does a trotting horse. Of course, I do not want to discourage the trotting horse. Our State is largely devoted to pro-

ducing trotters, and for those who want them they are a good horse; but for a pleasure horse I think the saddle horse is far superior, because it is a good harness horse, too, and goes fast enough for any road we have when in harness.

Q. (By Mr. CLARKE.) Are these horses trained on the farms where they are raised, or are they taken to villages and put under professional trainers?—A. The best specimens are usually bought by professional trainers and given their schooling at the edge of some town where he has a stable and good roads. They are shown first at the county fairs.

Q. Do not the young farmers get on to these methods somewhat and give some preliminary training to their colts?—A. A great many of them do; yes. I got a couple of them myself several years ago, and I got on to them and trained them to the gaits and sold them at very good prices.

Q. (By Mr. CONGER.) You say these make good driving horses?—A. They make excellent family horses, and also are excellent for pleasure driving. Perhaps they would not stretch out on the drive in New York and keep up with the horses the rich men drive there now in their races with one another.

Q. Does the use of them in harness deteriorate their value as saddle horses at all?—A. To some extent; yes. They are not quite so smooth after they are used much in harness.

Q. (By Mr. A. L. HARRIS.) Do you raise coach horses?—A. We raise more trotting horses. There have been some few coach stallions introduced of late.

Q. (By Mr. LITCHMAN.) How does the strain of horses produced in Kentucky compare with the horses of the Belmeade farm at Nashville?—A. Belmeade is a thoroughbred breeding establishment. Our horses, I think, compare with any in the world. We have always kept up with the very best in that line, and we have now Mr. Whitney's celebrated horse, Hamburger, there on one of the Kentucky farms. The blue grass tends to the best development, I think, of the race horse. The water, the soil, and the grass all seem adapted to the race horse.

Q. (By Mr. A. L. HARRIS.) Have you many stock farms devoted to the raising of horses?—A. Yes; a good many. I could not tell you how many; I could not even guess the number, but it is in the hundreds, and the industry is more or less carried on on nearly all of the farms through the better part of the country.

Q. By the small farmers?—A. Yes; they have the mares and they breed to good horses and they develop the colt; and one occasionally will strike it, like a miner, and make his mark on 1 or 2 horses; but most of them, I think, lose money by it where they do not go into the business regularly. They lose their heads. They pay too much and the returns are not what they expect.

Q. (By Mr. A. L. HARRIS.) What have you to say about earnings of capital employed in agriculture compared—say, with 50 years ago?—A. Of course, you understand that in the aggregate we produce products of more value than we did because we have a larger aggregate capital employed; but, acre for acre, I do not know whether we produce more wealth to the owner now than we did. I doubt it.

Q. Is capital employed in agriculture as profitable as employed in other lines of business?—A. Our people think not. I am inclined to their way of thinking.

Q. Can you give a reason why it should not be?—A. I hardly know how to account for it. I think I might raise a controversy by stating it, but my opinion is that agriculture has not had some of the advantages of legislation that manufacturing and some other lines of business have had.

Q. In what particular?—A. Well, in tariff legislation, for instance. I am inclined to believe—I am not an extremist on that point—but I am inclined to believe that the tendency of protection has been not toward the agricultural classes.

Q. Does that result from the fact that agricultural products are exports and that therefore the price is fixed abroad, or does it result from any internal conditions?—A. I am not by any means an extremist. While I have been an agriculturist I have always been in favor of reasonable encouragement being given to other lines of business, believing to some extent in the principle that the establishment of factories help the farmers around them and within reach of them. I am inclined to think with my people that Congress has gone a little too far in most instances, but I do not know whether I am right or not. I do not pretend to say. But this legislation has had a depressing effect on agriculture, according to my way of thinking.

Q. In what way?—A. The whole line of tariff duties.

Q. Does or does not the tariff duty help to increase the home market?—A. I have just stated that I believe it does to some extent. Now, whether that compensates for the other effects or not I do not pretend to say. I have not worked out that problem. I am very liberal on that point and if you can show it does, why, then, I am heartily with you.

Q. (By Mr. CONGER.) Can you point out or suggest any article in which additional benefits or in which benefits might come to agriculture by the inauguration of additional tariff duties? I understood you a few moments ago to say that in your opinion other lines of industry had received more encouragement than had agriculture in the way of these duties, and hence my question, Can you point out or suggest anything in which additional benefits or in which benefits might come to agriculture by the inauguration of additional duties?—A. From my own State I will take a single example. We are largely producers of tobacco. My State produces more than half of the tobacco produced in America for export and for domestic consumption. Now, in the internal revenue the tax is placed heavily on tobacco. It is a luxury and that is considered all right, but it bears heavily upon our people because, to the extent that tobacco is taxed before being manufactured, the tax bears down upon the raw leaf. Now, we believe it is right to raise a good portion of the revenue from the tax on tobacco, but we have always asked that it be put down as low as possible, knowing that the lower you put it the better price the farmer will get for his tobacco. That is one way. Another is that the export tobaccos are very largely "regie" tobaccos. You understand that the foreign Governments—the Italian, Spanish, and I believe the French—appoint an agent or sell the privilege to one syndicate (or one party, trust, or something) to supply all their tobaccos that are gotten from America. Well, they agree to furnish it at a certain price. They know what our range of tobacco is. They buy no other grades. Our people are absolutely at the mercy of these people as to the selling of that class of tobacco. They may put it in the export warehouses ready and the buyer may want it, but he is absolutely out of the market and there is nobody else to sell it to. You can not ship it to those countries—you can not ship it and put it in a bonded warehouse there and sell to a manufacturer. It has got to go through this one hand. We endeavored to get relief through a bill introduced by Hon. J. D. Clardy, of our State, who was in Congress three years ago, but he only got it through the lower House. Our object was to see if something could not be done to get those countries to relieve us so that we would have the sales of that product in the open market. The question now is just simply, "What will you give us for it?" not "We want this for it," at all. They absolutely control the price, and there is no other bidder for that tobacco. They do not allow us free access to the markets of the Old World, or, I should say, all those countries, and we think that legislation along that line of investigation might result in something that would be a benefit to our section of the country; that would benefit Kentucky, Tennessee, Indiana, and the southern part of Illinois, and Missouri as well. They all grow that class of tobacco largely.

Our farmers also complain of the competition with foreign-grown hemp. My information is that manila, sisal, and jute are admitted free of duty. We grow hemp in the blue-grass country. We used to grow 21,000,000 pounds of hemp a year. Our product now is about 4,000,000 pounds. I do not think that all that falling off is due to the fact that we have to compete with foreign hemp, because Burley tobacco took up a good deal of the hemp land, as it grows on the same soil. But our farmers complain that they can not compete with the Sisal hemp and the Manila hemp or jute and jute butts, that are introduced free of duty. They can produce as much, but they can not sell as much at a profitable figure. Hence they supply what is absolutely needed, about 4,000,000 or 5,000,000 pounds. The reduction from 21,000,000 pounds has not increased the price, but it has probably kept the price from falling flat.

Q. (By Mr. CLARKE.) What was the Kentucky-grown hemp used for mostly?—A. There was not as much of it used at home as there should have been, perhaps, but it went to New York, Boston, etc., and was used for cordage there and for domestic twine. I think the demand was diminished by the invention of iron ties for cotton. The tow of a great deal of hemp was once used for making cheap twine and rope for binding wheat, for baling cotton, and also for the outside baling of the cotton, but it is not used for these purposes now.

Q. Has there been some substitution of other materials for these uses?—A. There has been a substitution of the Sisal and Manila hemp, especially for the twine binders, that has affected it undoubtedly, and jute is used for twine, jute butts for bagging—all admitted free. The Kentucky hemp was used at first for making the twine for binding wheat, but it has been superseded by the Sisal, out of which a cheaper twine is made, and to this I think is partly due the diminishing hemp acreage in Kentucky, affecting injuriously not only the farmer who owns the land, but the colored man who is the main stay in its production and handling. If the price is satisfactory the labor is well rewarded.

Q. Are you aware that the wire grass of Wisconsin and Minnesota, which until within a very few years was a waste product entirely, is now used for bind-

ing twine to a considerable extent, making a cheaper twine than can be produced here in imported material, however cheap?—A. I have heard so, but I have never had any information on that subject. I say all these things affect the product of hemp to some extent, but I still think the chief cause of the decline in this industry is due to unjust discrimination against it in the tariff schedule.

Q. (By Mr. A. L. HARRIS.) What have you to say in regard to your State tax laws for raising the revenue for your State and for local purposes? Have you any suggestions to make in regard to amendments or changes for the farmers?—A. I think the law is sufficient, but the administration of it fails, or has heretofore, to bear equally upon farming lands and other property. The farmer's land lies before the assessor. He knows how many acres, and he knows what neighborhood it is in, and what it is worth, and his land is very apt to "catch it" for about all there is in it; that is, it will be assessed, all of it, up to its full value for taxation. There has been a great deal of other property, corporate property and bank capital, things of that kind, invisible property, that has escaped; but investigations are largely bringing that out now, and the evil may be corrected. It may be that in time the law will work equally, and there will be no complaint about it. The answers I get on that point are that agricultural lands are bearing more than their just proportion of taxation.

Q. How is your property valued for taxation?—A. Our rule is to value it for what it would bring at a fair voluntary sale.

Q. Who does that?—A. The assessor, and he is looked after by the board of supervisors for each county, and then there is an equalization board of the State that looks after each county. Until recently our railroads have largely escaped taxation, but we are now getting them in the hands of our railroad commission, and there is not so much complaint on that score.

Q. Is there any disposition on the part of the farmers of your State to move into other States to better their conditions?—A. Yes; for 10 or 15 years that tendency has existed to a considerable extent, they mostly moving West to cheaper lands.

Q. Is there any decline in the money value of your farm land per acre?—A. My information is that there is, that agricultural lands are not as valuable—that is to say, not as salable—as they were some years ago.

Q. Why is that?—A. I take it that it is largely due to the improved purchasing power of the money. If you go back 25 years I think you will find that under the gold standard the number of dollars that the land would bring is less. Of course, the dollars will buy as much of any other product.

Q. (By Mr. PHILLIPS.) About what is the price of good farm lands in your section, the average price per acre?—A. Our State varies so in the character of its soils that it would be very difficult to answer that question without confining myself to some locality. In the blue-grass section (where the value of the farm is considered rather than the value given to it by its beauty or location), I would say from \$30 to \$60 an acre; approaching the towns, where you get the advantage of better schools and near markets, from \$40 to \$80 an acre. Fancy places will sell from those prices up to \$150, according to improvements. In the western part of our State there are a few sections where the values will nearly equal those of the blue-grass section, but in the majority of the counties agricultural lands can be had at from \$10 to \$20 an acre with moderate improvements. In the mountain section the amount of timber and the prospects of minerals on the land will contribute largely to the selling value of the land; and no one could estimate, until he should know by the geological formation and character, what it would bring.

Q. (By Mr. A. L. HARRIS.) Is there any decline in the productive condition of your soil?—A. I do not think there is any very great decline, taking the whole State.

Q. Do you maintain a rotation of crops?—A. I mean by rotation that we can keep up and have kept up the fertility to about what it was 30 years back. We increased our wheat yield by the use of some stimulants, phosphate, etc., and that, of course, gives a chance then to improve it by some leguminous crop. We are using stock pease for clover, and lately the Department of Agriculture has introduced a legume known as the Soy bean or Soja bean that our people are beginning to like very much as a forage plant and as a renovator of the soil. It grows vigorously on poor land, and our experiments with it have been very satisfactory. It was introduced from Asia by the Department here.

Q. Have you any organization among your agriculturists?—A. We have numbers of organizations among the live-stock breeders, and recently I have endeavored to get farmers to organize county clubs. In fact, I have indicated to them that it would be of great assistance to the department over which I preside if they will do this, and I find that I do better if I go to a county where there is an organi-

zation. I have almost determined not to go among them until they are organized to hold institutes, because if I am backed by an organization of that kind, I get an audience all the time. Heretofore we have endeavored to hold institutes by appointment of dates. Before my term they would appoint a series of meetings, giving about 2 days to a place, and when they went to the designated place they would find no one there, or may be 2 or 3 people, or 3 or 4, or a dozen; but since then at all the institutes I have held I have had a fine attendance, because I have had the local backing of a club to work up interest. My plan, if I go to hold an institution, is to let the local club make the local arrangements, appoint a time that suits them, and make a local programme. We have an agricultural college in the State, and an experiment station contributed to by the Government here—and the professors go with me, my department paying expenses. At the institutes I sit at the table with the presiding officer. I am pretty good at condensing, and I take down what they say, catching all of the arguments pro and con on any of the subjects they bring up; then I write them all up and publish them in a supplement to an agricultural paper that I used to be connected with—I have no interest in it now—and thus let the information out to the public generally. The Public Printer does the printing of the supplement. I send it out under an arrangement with this paper, and it goes to the paper's Kentucky circulation. Then I buy about 2,000 extra copies of that paper, and we have lists of names of persons, who are not subscribers, and in the poorer sections where they do not take so many papers, and send to all these people a free copy with this supplement in it. I find the plan works well, and I am stirring up a good deal of interest. I usually let the local managers make the local programme, because they know what they want to talk about. I have these professors to answer them, and also I assign them subjects of their own; then I get all that is said published, and I have it back to the farmers in 10 days or 2 weeks. I believe that is the most successful way of arousing a feeling and getting the farmers to read and study these subjects.

Q. Is the interest in your institute work growing?—A. It is growing; yes.

Q. You spoke of your experiment station. Please state, if you will, the advantage the farmer derives from the experiment station.—A. The experiment station is under the direction of Professor Scovell, a very competent man, and he, by going out to these institutes and mixing with the farmers, finds out where the leaks are and where they want to improve, and also keeps in touch with the Agricultural Department here, getting the newer varieties of seeds and plants that are introduced and things of value (like these beans, for instance). He tests these things and tests all kinds of fertilizers also, has his alternate rows without fertilizer and with it, and he gives his opinions and the results of his experiments in bulletin form. These are sent free to the farmers, and then they find out what is the matter sometimes. We have also a professor of entomology and agrostology and geology there, and they go along and find out what the people want, and I get the information back to them in the way above described. By experimenting Professor Scovell shows them what is lacking in the soil. Sometimes he shows where there has been a failure in the use of fertilizers. He finds some man who has been following the wrong course and another who has secured no results. He tells them what the trouble is and how to remedy it.

Q. (By Mr. PHILLIPS.) You spoke of the Soy bean; is it used as a food, and is it nourishing?—A. It is not used as human food. Some people have eaten it, but it has a ranker taste than most people like; but it is very fine for stock. We sow it after the last plowing of corn and we turn the hogs in after the plant grows up, and they eat it all up; they like it very much. We cut it for hay and it makes a good hay for cattle. We think the right variety is fine hay for cattle and horses.

Q. You do not plow it down to enrich the soil?—A. We do that also—turn it under. It is a great nitrogen gatherer. It opens up the soil, loosens it up, and they say it is equal to clover. Of course, we know that red clover has no superior, but it will not grow in our country any more. An insect or something has gotten in that kills it. You get a good stand in the spring, and in the fall you have no clover. Someone claims it is a little maggot that gets into the root and kills the plant. They expect the clover to be good the next year, and when next year comes they will have none there. There is no enemy to the Soy bean, and it is a rank grower. In fact, some of the varieties grow so rank that nothing can be done with them. They can not cut them, and they can not turn them under—there is too much of them.

Q. (By Mr. A. L. HARRIS.) Is your agricultural college well supported by the farmers?—A. It is getting to be very well indeed; yes. The number of students now is about 860, of which 7 take the agricultural course alone.

Q. Do the graduates of your agricultural college return to the farms?—A. A good many of them. I have heard of quite a number of them going to other pursuits after they got back, but I know quite a number of young students there who

are on the farms now and have made very intelligent farmers. They are the entering wedge for better farming, I think, in our State. I am a great advocate of training farmers in the direction of farming.

Q. Has there been any reduction in the cost of transportation in your State by railroad or otherwise in the last few years?—A. Since 1895 there has been an increase of freight rates of from 10 to 30 per cent. Perhaps a general average increase of 12½ per cent would be a correct statement. In passenger rates there has been no change. Complaints of discrimination are numerous, and very few points are without complaint of high rates. The railroads justify the increase by a claim that commodities are worth more money in the markets and should for this reason bear a greater carrying charge. This statement is based upon information given me by our State railroad commission.

Q. What is the condition of the public roads in your State?—A. In our Blue-grass section we have excellent roads made of broken limestone rock. They are very fine. That is an up and down country, hilly, or nicely rolling, but the roads are good.

Q. Are they toll roads?—A. They were toll roads, but nearly all are free now. In the lower part of the State, where they have not the material to make pikes, the roads are bad. They are just ordinary dirt roads. There is some little improvement that has begun there, and we look for better roads and better bridges. I give attention to the roads in all my institute work. The discussion on the subject is a reminder—not that I expect to do much good myself. Locally it wakes them up and makes them think about the question, and they are changing the system of keeping up the roads.

Q. Have you any legislation to suggest on the subject of good roads?—A. My opinion is that roads kept up by taxation and road supervisors are better than those maintained by the "call out the hands" system, as they call it.

Q. Have you a road commission?—A. Some counties have commissioners, but there is not a State commission.

Q. In those counties where they have a commission is there improvement?—A. Yes; they are making better roads, for the reason that the commissioner studies the subject and he does not just go and scratch around to comply with the law, and, as a consequence, he works to improve one bad place permanently for 1 year and the next year he will go to another one; but under the old system the residents would be called out at a time when the bad holes were passable. Then they would scratch around a little and they would never come back again. The whole system, I think, was bad.

Q. You may state how this commission raises its funds to improve the roads.—A. The funds are raised by a county tax, but I believe in most of the counties the magisterial district in which the tax is paid controls the fund. It can be expended only in that district. They have different laws in different counties. I am not familiar with them.

Q. Is your road improvement macadam?—A. Only in the limestone section.

Q. Have you gravel in other portions of the State?—A. Not much. In some localities it exists. There are deposits of the finest gravel in the vicinity of Paducah.

Q. You may state, if you please, what the school age of children in your State is?—A. That is a subject I did not expect to be asked upon. Our school trustees are required to ascertain the number of children in each family from 6 to 20 years of age.

Q. What is the percentage enrolled in schools?—A. The total number in the State is about 80 per cent of the children.

Q. Is your common-school system sufficient for the educational needs of the farmer?—A. I would suggest for rural sections that the system should embrace something that bears upon agriculture, give the children a love for the occupation, make children believe that they are growing up to be farmers, keep them from leaving the farms, and make them realize that they ought to understand more about that subject than their fathers do or grandfathers did.

Q. Is your school system discussed in your farmers' institutes?—A. No; we have never discussed that in our farmers' institutes. We have educational institutes. The superintendent of public instruction holds institutes in the counties upon educational subjects, but I do not know whether or not he takes up the question of agricultural education.

Q. What is the condition of your schoolhouses?—A. Fairly good; they are improving.

Q. Is the qualification of your teachers good?—A. As good, I think, as they are in other States. We endeavor to have them good.

Q. Have you a high-school system in the country?—A. I think not; only in the cities and towns and larger villages.

Q. Your children in the country have no opportunity to secure the benefits of a high-school course?—A. Not unless they move into the cities or towns near to them. If they do not reside in the cities or towns, they pay tuition if they attend high schools there. A good many of our farmers have moved into Louisville and other cities and towns in the State to get the benefit of the high schools for their children. I might say right there that there is a tendency of the landowners in my State to leave the land in the hands of tenants and drift to cities. They go to Lexington or Louisville and other cities, leaving the farm, which they rent out. Some of them rent a house, but most of them buy houses in the cities. I do not like that tendency; but, of course, it is pursued because of the advantages of the schools and churches, and also because of the lack of household help in the country.

Q. Have you good local high schools?—A. I think so; yes. Nearly every county has one or more graded schools, including the high-school course.

Q. Have you free schoolbooks?—A. No.

Q. You have a free-school system?—A. Yes; we have a free-school system.

Q. Supported by taxation?—A. Yes. I think our State provides that if the scholar is not able to buy the books, they will be supplied. Each county, through the county judge, may expend \$200 annually for books for indigent children.

Q. Who teaches the colored schools?—A. Colored teachers. They are very efficient.

Q. You consider the colored school as efficient as the white school?—A. I think it is equally as good up to the point where they get to the high school.

Q. How is your school fund raised, and how is it distributed?—A. It is raised by taxation. All taxes for school purposes go into a common fund and the money is drawn out per capita. The colored pupils get the same as the white pupils.

Q. Have you a pure-food law in your State?—A. We have; yes.

Q. Is it satisfactory?—A. Yes; it is under the direction of the director of the experiment station. He is the official that sees that the law is enforced, and I think he was complaining the other day that the auditor had declined to or had been lax in furnishing him the means of going ahead with it, but he thought it would all be fixed up.

Q. Have you any suggestions to make in regard to a national pure-food law?—A. I am rather inclined to believe that the law should be national rather than State, because State lines are so uncertain nowadays, and interstate laws are such that the rights of a citizen of one State to do business in another State are so mixed up that we sometimes fail to find protection from a State law, because everybody outside has a right to do certain things under the national laws.

Q. Where would you lodge the authority to execute the law?—A. It would have to be lodged in the Federal courts.

Q. I mean the initiatory. Would you place it in the Agricultural Department?—A. For agricultural products, perhaps; but I see no reason for this in regard to drugs or food products generally.

Q. Have you any law to prevent the spread of disease among animals?—A. Yes.

Q. Is it sufficient?—A. That question is under the State board of health. He has a veterinary assistant. I think another trouble comes in there, that we can not enforce the law properly for the reason that the shipper from another State has certain rights under the Federal law that we can not properly regulate by a State law. That subject ought to go to the Federal authorities perhaps.

Q. Do you think there should be a Federal law?—A. Yes.

Q. For local safeguards, would it not be proper to have it under your department instead of the board of health?—A. In case of diseases of live stock, the live-stock people would know better what to do than the regular physicians. Stockmen apply to me in my department for remedies for diseases, and I have to turn them over to the medical or veterinary department. Possibly it would be better to let it go under the agricultural departments in the States.

Q. Is there anything that has not been touched upon that you wish to state?—

A. I wanted to say in reference to the last question that the appropriation for my department would have to be increased or else it would detract from other work. The appropriation for our agricultural bureau is \$13,000 a year, and out of that the salaries of the commissioner and his assistants are paid. All his printing expenses are charged up to this fund. There is not enough left in the department at present to undertake to regulate diseases among live stock. Of course it is quite an expensive thing to go and destroy a herd of cattle, for instance. We tried that once in our State, and the value increases very largely when you go to take them for public purposes and destroy them.

Q. Has the board of health authority to destroy diseased stock and compensate the owner?—A. It has. That is where the trouble comes in; they get to be too valuable when you destroy them. A runty calf that is killed on the railroad

sometimes becomes a very fine high-blooded animal, pedigree. We have to watch these points. I do not think there is anything else I could suggest. The people might be encouraged to improve the villages of the laboring men and make them more attractive. I believe I have been over that point. In our State we have the difficulty of having colored labor. We can not go ahead with the conditions that exist, and do what we would if they were all white, because the colored laborer when he gets his money and accumulates property feels just like one of us, and is entitled to a good deal of consideration as far as he goes; but it is impossible for people who have known and owned them as slaves to recognize that there is an equal social position for them. In some sparsely settled parts of the country, where there are not enough of them to make a village of their own, we can not take them in and make them a part of the community like we could if they were white people, even if they were lower in education than the majority. It is a very difficult question. I have great sympathy for the negro, and I am willing to do everything I can to elevate him; and if I find a community of them trying to farm and be independent, I am going to hold institutes among them and for them, and do what I can to improve their condition in that way.

Q. Did your reference to the average wage apply to the colored labor as well as the white labor?—A. Yes; it applies to all labor employed. The colored laborer gets as much as the white if he does as much.

Q. Is the colored laborer as efficient as the white laborer?—A. He is not quite as reliable. You will find sometimes that one colored man is worth a dozen whites of the kind that you find; but these German laborers are worth more, and get a little more wages than the average colored man, there being exceptions to the rule, of course.

Mr. CLARKE. I wish to call the witness's attention again to the duties on hemp. I understood him to inquire if there is a duty, without expressing any information or knowledge himself. (Here Mr. Clarke read the hemp schedule of the tariffs of 1894 and 1897:)

DUTIES ON HEMP, ETC.

"Hemp-seed oil, 10 cents a gallon; same in 1890, 1894, and 1897. Hemp and tow of hemp, \$20 a ton; hemp hackled, known as line of hemp, \$40 a ton; same under tariff of 1894, \$40 a ton; tow, \$10 a ton. Cables and cordage made of hemp, 2 cents a pound; tariff of 1897. Threads, twines, or cords, made from hemp yarns not finer than 5 lea, or number, 13 cents a pound; finer than 5, three-fourths of a cent for each additional number. Single hemp yarns, not finer than 5 lea, 1 cent a pound and 10 per cent ad valorem, tariff of 1897; same in tariff of 1894, 35 per cent ad valorem. Single yarns in gray, not finer than 8 lea, 7 cents a pound; finer than 8 and not finer than 80, 40 per cent ad valorem; above 80, 15 per cent ad valorem."

The WITNESS. Yes; I forgot what the duties were. I used to grow hemp, but I do not remember what the duties were then. It is, as I said before, the importation of manila, sisal, and jute free of duty that kills hemp-growing in Kentucky.

Q. (By Mr. CLARKE.) You think the culture of hemp in Kentucky would be likely to be increased if the tariff were more protective?—A. Yes; I think it would; it would become more profitable.

Q. Is the crop sufficiently profitable to supplant other crops in case the farmers had a domestic market?—A. I think that would naturally be the consequence. I do not mean to say by that that I would advocate a very high duty, because it might be putting a burden upon some one else for the benefit of our people, which we do not ask. I am only for a tariff for revenue, with incidental protection.

Q. (By Mr. FARQUHAR.) If the Constitution follows the flag and the United States statutes at large follow the Constitution, and you have free hemp from the Philippines, what is the condition of Kentucky hemp raisers?—A. I do not want to be led into a political discussion. I am an agriculturist.

Q. You have raised hemp; what is your idea practically if the whole product of these insular dependencies, the raw material, comes in free?—A. Hemp now, with a poor crop, in our State is selling at 5 cents a pound, or rather \$5 a hundred. That means 112 pounds from the brake. The kinds you spoke of come in competition with our hemp. The removal of that duty and the introduction of the manila hems free has certainly tended to lower the price. Our farmers can not grow hemp at \$4 a hundred. We grow only 4,000,000 or 5,000,000 pounds of hemp now. I think the production would be increased at \$5. It is profitable at \$5.

Q. (By Mr. CLARKE.) From a purely agricultural standpoint, is hemp a desirable crop to raise?—A. Very, indeed. It leaves the ground clean and in fine shape for any other crop. It can succeed itself for several years. It takes very little from the soil, being cut before seed ripens.

Q. Then if tariff conditions can be arranged so as to afford it substantially equal protection with other agricultural products, it is your opinion that the farmers of Kentucky would increase their crop of hemp rather than diminish it.—A. It is; yes. If we could be guaranteed the present price even, the product will increase and the colored labor employed would be better paid.

Q. (By Mr. PHILLIPS.) Have you anything else to state?—A. Nothing.

(Testimony closed.)

WASHINGTON, D. C., February 13, 1901.

TESTIMONY OF MR. HARRY HAMMOND.

The commission met at 10.15 a. m., Mr. Phillips presiding. At that time Mr. Harry Hammond was introduced as a witness, and, being first duly sworn, testified as follows:

Q. (By Mr. HARRIS.) You may state your name, post-office address, and occupation, please.—A. My name is Harry Hammond; my post-office address is Beach Island, S. C.; my occupation is that of, you might say, a cotton grower—a superannuated one, as I have given up pretty much of my work to my boys.

Q. How long have you been so engaged?—A. All my life. I was brought up on a cotton plantation.

Q. Have you held any position in the Government or State connected with agriculture?—A. I commenced work as professor of natural sciences in the University of Georgia, and gave it up for a more profitable thing—taking charge of one of my father's plantations. I came back after Appomattox and found everything broken to pieces, and have been trying to pick up the pieces ever since. I have stuck close to home, having a large family.

I was supervisor of one-third of the State for the Tenth Census. I wrote the article on cotton culture for South Carolina, and have since written two chapters on cotton culture and the handling of cotton products for Bulletin 33 of the United States Department of Agriculture on cotton planting, also for the agricultural department of South Carolina the Hand Book of the State.

Q. You may state, if you please, what is the condition of labor and capital employed in agriculture in your State and in the South generally, if your information goes that far. As you have "a plan of inquiry" before you, you may take up the subject as there outlined and treat each subject as fully as you desire.—A. I have some notes here which I will refer to. I have followed the questions in the topical plan of inquiry.

First, as to the number employed in agriculture during the last 50 years. Of course that is a statistical question to be answered from the returns of the Census. By the Ninth Census, 29 percent of the population in South Carolina; in the Tenth Census, 30 per cent; in the Eleventh Census, 20 per cent. There has been a falling off, therefore, in the number employed. In Hammond Township, where I reside, a purely agricultural community, or almost so, we had between the Tenth and Eleventh censuses no increase in the population; in fact we had a decrease of several hundred. The population has moved to town, and the movement continues. In the last year, 1900, 5 families moved. They are selling or renting their places in the township.

Comparative condition of agricultural labor: There are very few white agricultural laborers. They have gone into other occupations. The body of the negro laborers live from hand to mouth on daily or weekly wages, and that is especially true of the women, who only work during certain seasons of the year at cotton picking and cotton hoeing.

The effect of improved machinery on labor: The reaper and mower and cotton planter have displaced a great deal of labor. The more skilled and reliable laborers get an increase of say, 25 per cent over common labor, but that advance does not make up for the wages formerly paid to cradlers, hay cutters, and cotton-seed sowers. The last named occupation called for more laborers. The cradlers were paid more than double for the same work than is paid now. The old hand laborers were paid more than double for the work that is now done by machinery.

I would like to say in regard to that, that our State has petitioned the Department of Agriculture in Washington to have a division of mechanics. It is an extraordinary thing, which I can show to the commission if they care about it, how very small the amount of new machinery that has been brought in in the last 30 years for the use of agriculturists is. I do not know of any improvement that has been introduced except the corn harvester and shredder. And, as all the other

industries in the world are making their great boom now on mechanical improvements, agriculture which is in depressed condition stands as much in need of them as another; but we have no general center from which information in regard to these things can be disseminated.

Q. (By Mr. PHILLIPS.) Is not the reason for that condition the fact that you do not raise the same agricultural products in the South as are raised in the West and middle States, and that you do not require the harvester and shredding machine?—A. We have all these, but we want a great deal more in the way of agricultural improved machinery than we have. There are a great many things that could be done. The fact of the business is, that little has been done for the whole of the United States. The want is not peculiar to the South, but extends to the country at large. I prepared a paper for our club on that subject, and there are some extraordinary statements in it.

Q. I am surprised by your statement on that point.—A. You have but to refer to the report of the Commissioner of Agriculture and you will see the whole thing.

Q. (By Mr. A. L. HARRIS.) You have a paper prepared upon that subject?—A. Yes.

Q. Would you care to submit that to the commission as a part of your testimony?—A. That paper I prepared for our local agricultural society. I happened to come across it. It was done some years ago, but it is true to-day. The preamble is as follows:

(Reading:) "Whereas agriculture is neither a science nor an art, but an industry, and the physical basis of an industry is the mechanical devices and appliances which render its prosecution practicable and profitable, the prosperity and progress of the industry being largely dependent upon the increasing effectiveness of such inventions and devices. The records of the great industrial revolution which set in during the latter half of the last century, and has continued to the present day, gaining in force year by year, bears ample testimony to the correctness of this statement. Erase from history the names and works of Hargreaves, Arkwright, Crompton, Cartwright, Dary, Watt, Stevenson, Siemens, Bessemer, Edison, and their fellows, and the foundation of the great industrial advances in manufactures, mining, and transportation, with the stupendous additions they have made to the world's wealth and population, would be removed. The mechanical inventions of Tull, Whitney, Ransome, Manning, Hussy, McCormick, and Pitts have created a new agriculture that has filled the earth with a plenty undreamed of before. The single invention of the cotton gin has made it, for the first time, possible to clothe the whole human race, and has established an extensive culture which has done more to stimulate the commercial activity of the world than any heretofore undertaken by man.

"But interest and progress in the mechanics of agriculture seem to belong to a period that is past. The gin is more than a century old. Cultivators, horse hoes, and seed drills were used in this country before the Revolution. Steel hoes were manufactured and sold cheaper in 1831 than they can be bought for to-day. It is more than a generation since the American reapers, mowers, and thrashers took the first prizes at the Paris International Exposition of 1855, and since 144 bushels of wheat per hand was cut and thrashed daily on the Huffman ranch in California, a performance which could not be excelled, even if equaled, by the implements and machinery now in use. The period of greatest prosperity and development in agriculture was during the golden decade of 1850-1860. The increase in the value of farm implements and machinery in those 10 years was 62 per cent. In the two succeeding decades, notwithstanding the growth of the population, the vast areas of fresh lands brought under cultivation, and the enormous additions to the agricultural products of the country, the increase in the value of the implements and machinery employed on farms barely equaled the increase of the single decade preceding. The value of agricultural implements manufactured in the United States increased 150 per cent between 1850 and 1860 (we were supplying the trade of the world), between 1860 and 1870 the increase was only 122 per cent, and between 1870 and 1880 it fell to 75 per cent. The manufacture of farm implements has fallen more and more into the hands of large concerns, which have bought out smaller ones, and hold a monopoly of the business. One company, a harrow trust, has in recent years bought up 21 other companies and advanced the price of their products as much as 31 per cent. These trusts possess themselves of every new patent, holding it for their exclusive use, or what is worse, suppressing it, to avoid the additional expense of new and improved models. Experts declare that it would pay many manufacturers to give away their machines for the profit to be found in selling duplicates of parts that break or wear out from faulty construction. Side by side with the growth

of combinations among the manufacturers of farm machinery, the subdivision of farms has proceeded. The rural blacksmith has disappeared and the small farmer is left to contend single-handed with the gigantic corporations from whom alone he can obtain his tools. It might be thought that the numerous agricultural departments, colleges, and experimental stations, endowed so largely by the Federal and State governments, would strengthen the hands of the farmer in this exigency. But this is far from being the case. Among the 491 officials employed in 1892 in the 61 colleges and 52 experiment stations in the United States, there were 2 machinists employed in the specialty of beet sugar, 1 civil engineer, and 1 other engineer, only 5 altogether who were concerned with the mechanics and engineering of agriculture. Of the thousand and one courses of instruction given, only about 6 per cent appertained to the wide domain of the mechanics of agriculture. Looking back of the reports of the United States Department of Agriculture since 1891, no mention of a hoe is to be found for 20 years; of a plow for 17 years; of a reaper for 16 years; of a planter for 18 years; of a road for 19 years; of implements and machinery for 15 years, unless it be a machine for testing the strength of binding twine or an apparatus for stripping cocoons or spraying poisons. That inventions and improvements in these lines are of great importance every farmer knows full well from sad experience. That such improvements are being constantly attempted is shown by the records of the Patent Office. In the list of patents and inventions for the three months ending June 30, 1893, 25 improvements in plows and 21 in planters are entered. But the Agricultural Department, an offshoot from the Patent Office, appears anxious to obliterate all traces of its origin. Since 1870 it has led in a new departure, devoting its energies to botany, entomology, ornithology, chemistry, pomology, microscopy, and other sciences, to the entire exclusion of agricultural, mechanics, and engineering."

Q. (By Mr. CLARKE.) When was that paper written?—A. In 1894 at Beach Island, S. C. The entire lack of everything in agricultural machinery is very marked, and it is owing in a large part to the big concerns that take it up and do not care about farming improvements.

Q. Can you give us the data on which these statements about agricultural machinery were made?—A. It will be found in the census reports, and in the reports of the Department of Agriculture.

Q. You have given percentages of the increase in agricultural machinery. Are these percentages based on the same basic figure—the same starting point—or are they based on the new basis of each census?—A. On the new basis of each census.

Q. Now, can you give the number of machines that were put forth in each census period?—A. Yes, the value of them. The census returns give the value.

Q. Now, is it not a fact that the number and value were each larger from 1870 to 1880 than they were from 1860 to 1870 or from 1850 to 1860?—A. No, not as large as from 1850 to 1860. In 1870 the percentage was somewhat larger, but from 1870 to 1880 it fell off.

Q. I am not talking about percentages, but numbers and values?—A. I am talking about values.

Q. And you persist in the statement that they are larger?—A. Yes, I persist in the statement. There is the census report; you may look to it. I may be mistaken, I may have miscalculated it and made an arithmetical error, but the census is there to answer the question.

Q. (By Mr. FARQUHAR.) What remedy do you propose or where are you going to put this machinery? Do you intend to bring the machinery into the experiment stations and show the advantages of labor-saving machines through the mechanics and engineers?—A. It is a very difficult thing to make out. You can find generally there is a fault, but to rectify it is difficult. I should say the Department of Agriculture or, to go back in a certain degree to its parent, the Patent Office, should help in that line. Mr. Webster and Mr. Jefferson were both inventors. They established the whole thing for the improvement of agricultural machinery as much as for the dissemination of statistics, and I think that the thing ought to be looked into. What is practicable I may not say, but certainly when you are giving several hundred millions to the cause of war and 5,000,000 to the Department of Agriculture, it would not hurt to try and have experiments in the line of agricultural machinery.

Q. (By Mr. PHILLIPS.) Is not the machinery almost perfect so far as the agricultural business is concerned now, and is not that one reason why it can not be improved on?—A. No; it is far from being perfect. I saw an invention here that upsets the whole nature of plowing. It was made out in the Northwest—a plow that is followed by a roller to compact the soil in order to increase its capillarity and produce moisture. That is a new thing, but a thing the farmer will never hear of. If there is a bulletin written about it—if the Department of Agriculture has an increased appropriation for its bulletins and will write the bulletin on the

subject and distribute it among the farmers—they will know something about it. As it is, not 1 in 10,000 ever hears of it, as the dealers in these things want to run on the same lines. In fact, dealers in machinery control the whole business. They want to keep up their old stock.

Q. You think they would buy them up and suppress them?—A. Yes; I have known of such a course being pursued. I can not cite the case exactly, but I have heard of cases where dealers have suppressed machinery, and I believe they do. I have been told by agents engaged in selling machinery that there was more money in selling the duplicate parts than in selling the machines themselves. They make the machines cheap with the certainty of making the profits in repairs.

The fourth question is as to the causes of the irregularity of labor. It is the inclination common to all men to avoid the primeval curse whenever they can. I believe this applies perhaps less to the negro agricultural laborer than to any others. His work is not heavy, and the continuation of the methods in vogue during slavery render it lighter than many other occupations, such as no work before sunrise or after sunset, with an hour at noon in the winter and 2 or 3 hours in the summer, and no work in very wet or very cold weather. The average labor day on the farm I have always found to be less than 8 hours. Nevertheless there are immense losses not to be foreseen or provided for. Such losses occur occasionally to employers of labor by reason of its irregularity. It often happens that the loss of a day results in the loss of a season's crop. It was argued before emancipation that this irregularity would render agriculture unprofitable if not impossible. While this anticipation has not been fully realized, the many farmers who were bankrupted would with truth charge their failure largely to these causes. I lost, when I first started, 40 acres of cotton by the refusal of the hands to work on the 4th of July. It was a political superstition that their rights as free-men would be taken away if they worked on the 4th of July.

Q. (By Mr. A. L. HARRIS.) Please explain how 1 day is so important?—A. I was planting 300 acres of cotton, and made all my arrangements and brought hands in to work out that 40 acres on the 4th of July. I went down and found not a man in the field. That was utterly unexpected on my part. A rain fell the next day, and the ground was covered with grass before I could get back to it.

Q. (By Mr. CLARKE.) You knew that the Fourth of July was a national holiday then from away back, I suppose?—A. Yes; but we did not have many holidays with us.

Q. Has it not been customary to observe the Fourth of July as a holiday in your section?—A. Oh, yes; but I will tell you what the negroes said—why it was unexpected with me. I went down and found them sitting in the doors and I said, Why arn't you men in the field to-day? They said they had been told that if they worked on the Fourth of July they could not prosecute a man who seduced their daughters. This is the comfort I got.

Q. (By Mr. LITCHMANN.) Is that the answer given to you or was it really a fact? Could you corroborate it from any other source?—A. That was the reply made to me.

Q. Did you verify it from any other source?—A. Of course not. It was what had got out among them; how, I do not know.

Q. That was pretty near to the close of the war?—A. That is true.

Q. And before any general methods of education had been adopted in the South for the negroes?—A. Yes; they would not believe that now.

Q. (By Mr. CLARKE.) Could you have planned your work so as to avoid that loss if you had known they were unwilling to work?—A. If I had had that information I could have planned it differently; but the refusal to work was totally unexpected. The same thing occurs now from various reasons. Expensive methods have been adopted to remedy this evil. Farmers build numerous houses on their land for day laborers, so that if one fails another may be secured. They have gardens, often rent pieces of land, allow firewood, and all that sort of thing, and the houses become pauper warrens. Women and children pick up a precarious living out of the assets of the community—fruit, fowls, game, and fish. Another method is to keep a commissary, and furnish supplies on credit. Although the profits charged are high, it is doubtful if the net gain to the employer amounts to much, as he often has to be repaid by work that he would not have paid cash for; and this notwithstanding the negro laborer very seldom shirks or repudiates his debt.

Transient labor: There is none except in the vicinity of towns. There it is esteemed a great advantage to farmers and they always have a full supply of day labor to draw on without any charges for its keep. You often see teams in the cotton-picking season driving to town daily and back to transport cotton pickers.

As to the average days employed in the year: A good negro laborer finds employment, and will work the year through except holidays for funerals and

society meetings, and a few days at Christmas. There is a deep-rooted desire to have their Saturdays, and they collect in crowds on that day at the store or in town. The average laborer works from 200 to 250 days in the year.

As to the tendency to go to town, and the remedy: My section furnishes no exception to the universal and increasing tendency of the rural population to drift toward the towns. The improvements in transportation, the daily mail, the telegraph, have mobilized country life. Country people who formerly were satisfied with their weekly paper, who went to town annually or semiannually, in some instances not more than 2 or 3 times during a long life, can now go quickly, safely, pleasantly, and cheaply several times a day. The mail once a day no longer satisfies them; they want free delivery twice a day. They want the morning telegrams from China, the Philippines, and the Transvaal. Besides, town life with better policing has become more secure. Cheap coal, cheap lights, convenient water supply offer inducements; society and amusements draw the young; the chance to speculate, to make a sudden rise in fortunes, to get in the swim attracts others. The wages of servants are fabulously high to the country laborer, and the rotation among them from one master to another gives all a chance sooner or later to try their fortunes, however little permanency there may be in them. All these things, and many more of the same sort have acted and reacted between the town and the country, and the country has become permeated with tendencies to town life and the effort to imitate.

It was predicted that the negroes would leave the cornfields and fill the towns in case of emancipation. That prediction has not been realized suddenly, as we anticipated it would be, but it seems to be approaching; it is working slowly and surely.

Q. (By Mr. FARQUHAR.) What are the inducements to go to the town, the practical inducements?—A. They are not any better off in town. The town and the country are all in the great struggle for the fittest, and in that struggle the unfittest fail. That is all. There are more chances in town than anywhere else.

Q. Are the wages in town so much higher than they are in the country?—A. The wages of agricultural labor is the same—that is to say, the agricultural labor that works in the fields immediately around town are the same that they are farther away. The wages for domestic servants and men in stores and for work of that sort are very much better.

Q. (By Mr. CLARKE.) Can you state the wages for domestic servants?—A. In the city of Augusta the wages of a housemaid will run anywhere from \$8 to \$15 per month; those of cooks, from \$8 to \$15; and those of house servants sometimes go as high as \$20.

Q. And you call those wages high?—A. Those wages are high in comparison with \$8 to \$12 on the farm.

Q. (By Mr. FARQUHAR.) Do you notice much of a return to the country of these migratory people from the city after they have experienced the dullness of work and everything else in the city?—A. They very seldom return. They shift from place to place, go from one town to another. There is a great mobility among the working population in that way. They go, for instance, to Augusta, then down to Savannah, and perhaps take a season in Charleston stevedoring. The better class of servants go to the winter resorts of the South and to the summer resorts of the North in the summer. They go backwards and forwards, and get very good wages. No; I see no return to country life.

Q. (By Mr. LITCHMAN.) Is that typical of the South any more than of the North?—A. It may not be. I do not know as to the North.

Q. Is it not a fact that the statistics show that the urban population grows very rapidly all over the country?—A. Yes.

Q. Would it not be a fact, then, that the same tendencies that produce that result in one section of the country would be likely to operate in the South?—A. Yes.

Q. (By Mr. FARQUHAR.) Do these colored people, where they have no knowledge through friends or otherwise of a job, take the risk of moving, simply, and settling down until a job comes to them?—A. Yes. It is astonishing to see how they go off all of a sudden. It has not been a month since I lost my cook. She just went off to a place she never had known or heard of before, on account of no fault with us, but to follow her husband, and she has been there now two months without any employment at all. One gets very tired of sitting down in the country and seeing nothing but the humdrum of life there. One great cause is the lack of interest in country life.

Farmers engage more in buying and selling than in providing. Gardens and orchards and the various perquisites of country life are neglected. Fertilizers and implements are purchased which used to be made at home. The same is true of work animals. We made nearly all of our agricultural implements on the plan-

subject and distribute it among the farmers—they will know something about it. As it is, not 1 in 10,000 ever hears of it, as the dealers in these things want to run on the same lines. In fact, dealers in machinery control the whole business. They want to keep up their old stock.

Q. You think they would buy them up and suppress them?—A. Yes; I have known of such a course being pursued. I can not cite the case exactly, but I have heard of cases where dealers have suppressed machinery, and I believe they do. I have been told by agents engaged in selling machinery that there was more money in selling the duplicate parts than in selling the machines themselves. They make the machines cheap with the certainty of making the profits in repairs.

The fourth question is as to the causes of the irregularity of labor. It is the inclination common to all men to avoid the primeval curse whenever they can. I believe this applies perhaps less to the negro agricultural laborer than to any others. His work is not heavy, and the continuation of the methods in vogue during slavery render it lighter than many other occupations, such as no work before sunrise or after sunset, with an hour at noon in the winter and 2 or 3 hours in the summer, and no work in very wet or very cold weather. The average labor day on the farm I have always found to be less than 8 hours. Nevertheless there are immense losses not to be foreseen or provided for. Such losses occur occasionally to employers of labor by reason of its irregularity. It often happens that the loss of a day results in the loss of a season's crop. It was argued before emancipation that this irregularity would render agriculture unprofitable if not impossible. While this anticipation has not been fully realized, the many farmers who were bankrupted would with truth charge their failure largely to these causes. I lost, when I first started, 40 acres of cotton by the refusal of the hands to work on the 4th of July. It was a political superstition that their rights as free-men would be taken away if they worked on the 4th of July.

Q. (By Mr. A. L. HARRIS.) Please explain how 1 day is so important?—A. I was planting 300 acres of cotton, and made all my arrangements and brought hands in to work out that 40 acres on the 4th of July. I went down and found not a man in the field. That was utterly unexpected on my part. A rain fell the next day, and the ground was covered with grass before I could get back to it.

Q. (By Mr. CLARKE.) You knew that the Fourth of July was a national holiday then from away back, I suppose?—A. Yes; but we did not have many holidays with us.

Q. Has it not been customary to observe the Fourth of July as a holiday in your section?—A. Oh, yes; but I will tell you what the negroes said—why it was unexpected with me. I went down and found them sitting in the doors and I said, Why arn't you men in the field to-day? They said they had been told that if they worked on the Fourth of July they could not prosecute a man who seduced their daughters. This is the comfort I got.

Q. (By Mr. LITCHMANN.) Is that the answer given to you or was it really a fact? Could you corroborate it from any other source?—A. That was the reply made to me.

Q. Did you verify it from any other source?—A. Of course not. It was what had got out among them; how, I do not know.

Q. That was pretty near to the close of the war?—A. That is true.

Q. And before any general methods of education had been adopted in the South for the negroes?—A. Yes; they would not believe that now.

Q. (By Mr. CLARKE.) Could you have planned your work so as to avoid that loss if you had known they were unwilling to work?—A. If I had had that information I could have planned it differently; but the refusal to work was totally unexpected. The same thing occurs now from various reasons. Expensive methods have been adopted to remedy this evil. Farmers build numerous houses on their land for day laborers, so that if one fails another may be secured. They have gardens, often rent pieces of land, allow firewood, and all that sort of thing, and the houses become pauper warrens. Women and children pick up a precarious living out of the assets of the community—fruit, fowls, game, and fish. Another method is to keep a commissary, and furnish supplies on credit. Although the profits charged are high, it is doubtful if the net gain to the employer amounts to much, as he often has to be repaid by work that he would not have paid cash for; and this notwithstanding the negro laborer very seldom shirks or repudiates his debt.

Transient labor: There is none except in the vicinity of towns. There it is esteemed a great advantage to farmers and they always have a full supply of day labor to draw on without any charges for its keep. You often see teams in the cotton-picking season driving to town daily and back to transport cotton pickers.

As to the average days employed in the year: A good negro laborer finds employment, and will work the year through except holidays for funerals and

Q. Are these houses located in groups, or distributed individually?—A. Distributed as much as possible. The colored laborer likes to have a few chickens, a hog, and sometimes a cow, and be by himself. The colored people grow a little among themselves in a good-natured sort of way; the women do, and every man likes to be by himself.

Q. (By Mr. CLARKE.) And still they would like to be near enough together for social purposes?—A. Yes; they have their social societies and their funeral benevolent societies to bury them. They have a grand occasion on a funeral.

Q. A former witness testified that he thought the building of laborers' cottages somewhere near together, perhaps in little villages, in farming neighborhoods, would tend to make country life more attractive to them. What is your opinion about that?—A. Well, I suppose it would if they could be properly policed. It would have to be done on such a scale that they would be policed, something like they were under the old plantation system; I think they would prefer it, too.

Q. (By Mr. LITCHMAN.) Would not such an arrangement tend to make the population more permanent?—A. Possibly it might. You know the negroes have collected all around the towns, and the negro quarter around the towns now is as marked a feature in a Southern town as a Jews' ghetto anywhere in Europe; they have spread all around the towns, and they get along tolerably well there, but they have a police to keep the peace with them.

Payment of rent in kind, formerly one-fourth the corn, one-fifth the cotton, is passing out of practice. That system was taken from the Mosaic law. Money rents are generally paid at the rate of \$2 an acre for average land, and more for the best quality, and is increasing. Crops on halves, the employer finding land, teams, implements, furnishing house, fuel, and garden, and one-half the fertilizers, is growing in favor. The perquisites of the labor are made up to the landlord in that labor is 54 per cent of the cotton crop, and the additional security that the crop will be carefully gathered so as to bring full prices as first-class staple. That is an important item; the laborer gathers the crop. The cost of ginning, steam transportation to market, charges for insurance, and selling are shared equally, and are more than covered by the sale of the seed, the balance from this last adding a dollar or two to the share of the cropper. The land deteriorates rapidly where rented, but is kept up under the share system.

Some advances and liens on growing and prospective crops are general. The largest landholders and planters are often bankers; the next largest are customers of the banks. Small proprietors and renters get advances from the cotton factors, say, of \$10 a bale, secured by lien or chattel mortgage. The cotton crop is grown on a credit of at least \$100,000,000 annually, and if the credit system were abolished it would be materially reduced and the price increased. Meanwhile the cheap cotton furnished by credit is a vast advantage to the world at large, and incidentally to manufacturers, however injurious it may be to a certain class of substantial yeomanry who provide it. Attempts are made at every session of the legislature to repeal the lien laws, but the mercantile influences are too strong to allow that to be done. Formerly the small farmer was not infrequently raided under these lien laws, but of recent years the law is seldom resorted to; the victim, if there is one, has been trained to yield to the inevitable without resistance. It is one of the cases in which experience with the law has rendered it almost inoperative.

Q. (By Mr. A. L. HARRIS.) What have you to say on the subject of immigration?—A. Immigration is said to follow the parallels of latitude. The presence of the black race in the South is an obstacle, and we have little to hope for or to fear from immigration. Even the Irish ditcher, who used to visit us frequently, seldom makes his appearance now. Some Germans and Frenchmen settle down and make a good thing of it. I have known some of them to get along very well.

Colored labor constitutes as much as 75 per cent of the rural laboring population. Some 75 per cent of colored laborers are engaged in agriculture. They are used almost exclusively in the ginneries and oil mills, to a large extent in railroading as section hands, firemen, porters, trackmen, etc. Up to this date they have not been successfully utilized in cotton manufactures, though they were so employed during slavery times. Testimony as to their effectiveness and reliability in employments outside of agriculture shows that their employers preferred them to white laborers in the majority of cases.

That testimony will be found in letters written to the Tradesmen's Journal, published in Chattanooga. Some fifty-odd letters that were written by persons from rolling mills and small manufacturing establishments are to be found in that paper's files.

Q. (By Mr. CLARKE.) How long ago?—A. About 1885.

Q. (By Mr. KENNEDY.) Are they employed in positions as engineers on the railroad, generally or exceptionally?—A. I do not know of any colored engineers.

Q. Firemen, I should say?—A. As firemen they are very common in our country.

Q. More colored firemen than white?—A. Yes.

Q. Do they ever get promoted to the position of engineer?—A. Not that I know of. I am not much acquainted with the railroad employees, except that I go up and see them paid off occasionally. They get very good wages; most of their pay is taken up in advances, however, I notice.

Q. (By Mr. A. L. HARRIS.) Are they permitted to run a stationary engine?—A. Oh, yes; my boys have an oil mill, and we have negro laborers there who do everything. Mr. Tompkins says that it requires more mechanical ability to conduct a gin properly than to run a cotton factory, to spin and weave in a cotton factory. Our ginners are all negroes. There is no reason on earth why the negroes should not be put in cotton factories except race prejudice.

Q. (By Mr. FARQUHAR.) Q. Have you any knowledge of the fact that they have been tried in factories; tried and discarded for white labor?—A. Yes; they have been a failure there ever since the war. Before the war, though, there were the Saluda mills, which were run entirely at one time by negro labor, and in part by negro labor and white labor, mixed labor at another time. In both cases the mills are reported to have been profitable.

Q. (By Mr. A. L. HARRIS.) If the negro laborers were efficient then why are they not efficient now—what is the reason?—A. I see no reason in the world why they should not be.

Q. (By Mr. CLARKE.) I have seen an explanation recently to the effect that these cotton mills in which negro labor has been tried are located in or near cities, and that the colored operatives are unwilling to work continuously as white operatives will, and that they want to take a day off frequently, and that that practice really destroys the effectiveness of a manufactory. Is that, in your opinion, a correct explanation?—A. I think not, because the negroes work very faithfully all the time. I have tried both negro and white labor on the plantation, and I say that the negro works better than the white man, more continuously; he doesn't want so many holidays. I see no reason why negro labor should not be employed in cotton factories. I refer you to the Handbook of South Carolina, where the statement is made concerning these mills run before the war by slave labor—by colored labor.

Q. I heard another explanation, a funny one, to the effect that the monotonous hum of the machinery puts a good many of them to sleep. Is there anything to that?—A. Well, the negro "possum" hunter is a nocturnal animal, but I do not think he is as sleepy as he used to be in old times; about the same as the white man. I do not think they go to sleep any more than white men. You know the fate of the first steam engine that was ever run on a South Carolina road. The first locomotive steam engine ever built in the world was built for a South Carolina railroad extending from Charleston to Augusta, and it was called "the farmers' best friend." After running one or two trips the train stopped for breakfast at a place called Summerville. The engineer stopped off and left his negro fireman with the engine. He was disturbed by the steam from the safety valve, so he sat down on the lever, and in a few minutes the whole concern was blown to pieces. That was the first railroad car that came to its end, and there was an ordinance passed that they should not use any more of those cars without putting a freight car loaded with 6 bales of cotton between the passenger cars and the engine so that the passengers would not be injured. [Laughter.] That don't happen now. That was in the early efforts at railroads.

Q. (By Mr. KENNEDY.) Is it true that South Carolina built the first railroad?—A. Yes, that is true. If you read Adams's book, *The Railroad Problem*, you will see the statement that the South Carolina railroad was the first railroad built to use locomotives in steam transportation. The other railroads were intended to be operated by traction.

Q. (By Mr. CLARKE.) Do you remember what year that was put in operation?—A. About 1832.

Q. Have you ever read that a railroad from Quincy to Neponset River was put in operation in 1828 in Massachusetts?—A. Yes; that was sort of a tramway. I only go by Adams's book. It is an authority on railroads, railroad administration, by Mr. Adams, who was on the Interstate Commerce Commission. We started the first canal, too, and we were among the first to go into the canal business; the Santee Canal was started before the Erie Canal. South Carolina has led in some twenty-odd different things.

I want to quote an extract from the book entitled "Race Problems of the South" (Montgomery Conference). Alfred Moore Waddell is the speaker and he is referring to the situation in North Carolina respecting the negroes. He says:

"Crimes of all sorts increased alarmingly, and went unpunished. Negro jurors, who sat in every case that was tried, refused, in the face of the most overwhelming and undisputed evidence, to convict negro criminals guilty of outrageous offenses. The city authorities and police of some places, including the city in which I live, became a laughing-stock to law breakers, and objects of contempt to all good citizens. Eastern North Carolina became a negro paradise, and immigration to it began from all quarters. Idle and drunken negroes infested the streets of Wilmington day and night, and grew more and more insolent and aggressive. Ladies were frequently and grossly insulted, and citizens assaulted and robbed in broad daylight. Burglaries were of almost nightly occurrence and no arrest followed. A negro newspaper was established, and crowned a series of offensive articles by an attack upon the virtue of white women in general. Another election was pending and threats of a demand for a still larger share of offices were made. That election was one of the quietest ever held in the State, and the negroes polled about 90 per cent of their strength, but a large proportion of their former white allies deserted them because of their conduct, and the party was beaten. Then, and not until then, the white people asserted their supremacy in an unmistakable way, and they intend to preserve it at all hazards forever. It was not the work of ignorant enemies of the negroes, but the long-delayed and spontaneous action of all the white people, united for the common purpose of preserving their civilization. Of course there was much misrepresentation of the facts." * * *

The large negro population on the coast of South Carolina is quite different from this here described. The mayor of Beaufort says the town is remarkable for quiet and good order. For 20 years past not a single individual has been killed or seriously injured in any disturbance within the corporate limits. (See Handbook of South Carolina, p. 663.) That is the statement of the mayor of Beaufort, and Beaufort is perhaps the blackest spot in the whole South; that is to say, the negro population predominate more there than anywhere else. There is a peculiar historical fact connected with that town that I would like to mention to the commission. That is the place where the Federal troops first set the negroes free. It was done on those islands in the neighborhood of Beaufort, and they are now there the predominant race, and this mayor refers to them as a quiet community. A most peculiar thing is this Quatrefages in his book on the human race asserts the fact that the African lived on these islands long before the discovery of America by Christopher Columbus. He is high authority, and he says that the Yamasee Indians were negroes, what were known afterwards as the fiercest of the Indian tribes of the South—the well-known Yamasee Indians were Africans.

Q. (By Mr. PHILLIPS.) Is it a fact that they were much darker than the other Indians?—A. Yes; it is a fact.

Q. And the hair was different, too?—A. So it is stated by one of the most distinguished ethnologists in the world. Another corroborative proof is that the Spaniards found that 1 negro was equal to 10 Indians for work, and they therefore imported these Indian negroes and carried them to the West Indies to experiment with.

The State guarantees \$3 per pupil enrolled in case the school taxes do not produce that much, and allows each school district to levy a maximum tax of 4 per cent on property for the maintenance of the schools.

The school law requires that instruction be given in agriculture in the public schools. Little has been done in this direction. In our school district a school has recently been opened in which botany and nature study are taught, and we are going to try and develop the school on the agricultural line.

Clemson College is an excellent technical school with professors and full equipment of laboratories and work shops, including a very complete textile school. There are some 400 students in attendance, and several hundred applicants have been refused for lack of accommodations. There is also a negro school at Orangeburg, which is partly supported by the State and partly by the Government, which is said to be doing very good work.

Q. (By Mr. A. L. HARRIS.) How is your school fund raised?—A. The school fund is raised by a State tax of 3 mills on property and by a \$1 poll tax, the poll tax being expended in the district in which it is raised. The other tax—the 3-mill tax—is divided in the county.

Q. Your poll tax goes to the support of the common schools?—A. To the support of the common schools in the locality in which it is collected.

Q. Your schools are divided into colored and white schools, are they?—A. Yes.

Q. Do the colored schools get the same amount per capita that the white schools get?—A. No; I can not give the exact proportion in money, but the plan is this: The law allows the trustees of the school district to distribute the funds

according to their best judgment, and they generally pay higher salaries for teachers and give a longer term to the white people.

Q. How long are your schools conducted during the year?—A. I would say for 4 to 5 months for colored and for 5 to 6 months for white children.

Q. Are the same studies required?—A. Substantially the same.

Q. Are the teachers colored or white in the colored schools?—A. Unfortunately the teachers of the colored schools are colored. Those in the white schools are white.

Q. What is the character of the schoolhouses?—A. The schoolhouses are very poor. We have a good school in my immediate neighborhood with 10 acres of land, a 2-story building, with as good an equipment as a city schoolhouse, that the white people have built within the last 2 or 3 years, but, as a general rule, the schools are very poor. The worst feature of the school business is that the superintendents of education are political characters generally, without any culture whatever, and are paid only \$400 or \$500 a year. It is simply absurd to suppose that such a man is fit to carry on education. He is paid \$400 a year to disburse \$30,000 a year, and, consequently, it is wasted and badly administered in every way.

Q. What is the average salary that your school-teachers get?—A. The colored people get \$30 a month and the white from \$40 to \$45, the full price. The negroes are willing to take the place for little or nothing.

Q. Are the teachers equally well qualified?—A. No; not at all.

Q. Have you any requirements for qualifications of teachers?—A. Yes; we have competitive examinations. Sometimes they come before the board of trustees, but there is an indifference on the part of the county trustees. The inefficiency of the county superintendents is the trouble with the whole thing. Mr. McMahon has done all he could to improve that thing, and there have been some very good suggestions, but the legislature would not listen to them. For instance, the members of the legislature are restrained by the idea of local self-government. They would not allow a good superintendent to be brought from one county to serve in another; they want the money, the miserable little \$400 he gets for the county.

Q. Is your territory divided into school districts?—A. Yes; into school districts. I have been anxious to be a school trustee myself, and that is the only office I ever announced myself as a candidate for—a district trustee of the school where I live. I went down and told my friends that I would like to be a trustee, but the voters elected a negro instead of myself for the place. The election occurred in Republican times.

Q. Please describe an average schoolhouse in the country?—A. A white schoolhouse would be usually 30 feet by 20, a weatherboarded building, without ceilings; with 2 chimneys, with homemade desks and seats for the children, the whole costing about \$200. That is the best style of country schoolhouse. The negro schoolhouses are about one-third that size, with ordinary benches and 3 fire-places. They are not very creditable establishments.

Q. What branches are taught in your common schools?—A. For 3 hours the State requires instruction in agriculture, but there is nothing done in that line. I saw a negro schoolmaster with a book on hygiene in his pocket, something of that sort, and in fact I think that in the rural schools the money is about as nearly wasted as can be.

Q. (By Mr. CLARKE.) Does the State furnish the schoolbooks, or does the district furnish them?—A. In the regular schools the State does not furnish them, but it determines the price and all that, and the same books are to be used for a period of 5 years. The fact of the business is simply this, that since this common-school system has come in South Carolina, it is my opinion, from as many facts as I have been able to collect, that there is less per capita spent upon education in the schools than was spent when the schools were supported voluntarily by the people. The parents think that the State has to do everything, and that they are to do nothing; that they are to send their children to school, and that they are to be instructed, the only expense put upon them being the purchase of books. Then they complain that they have the expense of purchasing the books.

Q. (By Mr. A. L. HARRIS.) Is that the way you account for the indifference?—A. The indifference comes from the lack of education in the whole country.

Q. Where you have a white school and a colored school in the same district, is each sufficiently well attended to make it an efficient school?—A. In our white school in my district we have about 35 or 40 pupils; the negro schools, I think, have 200 enrolled. Unfortunately the pay is distributed according to the enrollment, and not according to the population, and in the negro schools there is a good deal of cheating about the enrollment. The attendance is not as regular as it should be. The teacher naturally wants to get all the pupils he can, and have them enrolled.

Q. Do you draw the State fund according to the number enrolled?—A. Yes.

Q. Is it drawn equally by colored and white?—A. No, it is drawn for the whole district and distributed by trustees.

Q. Is that distribution fairly equitable?—A. I suppose it is; the money does the most good in the white schools. The wording of the law is that it shall be distributed according to the best uses that can be made of it.

Q. Is that latitude given the district trustees?—A. A district is an area of country comprising not more than 40 square miles nor less than 9 square miles. Formerly there were 106 square miles in our district and there were half a dozen little schools. Everybody wanted a schoolhouse put up, and a great many of them did put up schoolhouses to get the teachers and funds distributed. The schools amounted to nothing, the plan being to teach two or three months in one place, and then some little time in another.

Q. Have you subdistricts?—A. No, we have no subdistricts; the law says a district shall not be less than 9 square miles and not more than 40.

Q. Does that give sufficient facility for all to attend school?—A. Yes. I think it makes the longest walk in our district about 3 miles. We propose to get transportation there if we can.

Q. You say that in your district the enrollment of the colored children is about 200. How many of those attend school?—A. They all attend at times; they attend more or less; a day in a week; 2 or 3 days in a week. They pretend to keep account of the attendance, but I don't think they do.

Q. Have you a compulsory law?—A. No.

Q. Are your schoolhouses sufficiently large to accommodate that number?—A. Yes; they all seem to get inside.

Q. Have they sufficient room when they get inside?—A. I suppose not, not healthy room, not breathing space.

Q. You spoke of the school furnishings being homemade. Could you briefly describe the desks and seats? How they are constructed, and out of what material?—A. They are constructed out of pine and on the model of the improved school bench, though of course not at all equal to it. There is a seat and a desk in front of it, just as near an imitation as an ordinary country carpenter with coarse material and tools can make of a good school seat.

Q. Each pupil has a seat to himself or herself?—A. Yes; that is, in the white schools. I think in the negro schools they only have a series of benches set around.

Q. Do they have a desk to write on in the colored school?—A. I could not answer that question. I have not been inside a colored schoolhouse.

Q. The benches are merely long benches setting side by side?—A. Yes; I think so; that is an inheritance of the old school days before the war. That is all we had then, and then a table to write on. It is a question with us what is to be done. Education for the people is one of the things that has not been worked out yet at all. The school that I am trustee of has an independent endowment of some \$12,000, and we have a very good, model schoolhouse. I have not been paying any attention to the other schools. I have been trying to get enough funds to keep ours going 8 or 9 months. I did write to Orangeburg to see if we could not get a better teacher for the negro schools, but I did not succeed.

Q. Are your teachers male or female?—A. They are largely female for the white schools.

Q. And for the colored schools?—A. The colored schools have been getting a little better pay for the last year or two, and the teacher brings in his daughter.

Q. Does the colored pupil take readily to learning?—A. I think they would; they learn very little though.

Q. With equal opportunities?—A. Oh, yes; with equal opportunities they learn as well as the white people. We try that sometimes with domestic servants. My children teach them, and they find them very apt to learn. They learn to read and write, and acquire the elementary studies as quickly as anybody. You may say on the whole that the white intellect is superior to the negro intellect, but you pick out a dozen white men and a dozen negroes in the same condition of life, and I do not think there will be much difference between them. A teacher in the West Indies says that he has been teaching mulattoes, whites, and negroes, in Jamaica, all in one school, and that he sees no intellectual difference between the races, but what he does see is, that where the parents take an interest in the education of the children, those children, whether white, or mulatto, or black, get ahead of the others. The whole thing depends upon the interest of the parents.

Q. Does it spoil the colored child to get an education?—A. I don't see how it does.

Q. Is he equally as faithful after getting an education as before?—A. Yes.

Q. Is he better qualified to do service?—A. Now and then they will do a little forgery, but white people will do the same thing, in my opinion. I do not see any difference.

Q. (By Mr. CLARKE.) I would like to inquire if there is any tendency of public opinion in your State to dispense with the negro schools or to refrain from educating the negro?—A. There are some good negro schools in Carolina where Northern people have come into the towns and taught. The higher education I think is very well attended to in Carolina. Mr. Miller, the president of the negro school at Orangeburg, wrote a most forcible reply to Senator Hoar about his speech in Charleston. He is a negro.

Q. Is it your belief that the white people of South Carolina generally favor the education of negroes and are content to improve the facilities for that education?—A. I think so; I believe they would like to aid them in that respect.

Q. (By Mr. A. L. HARRIS.) Now, you may proceed to the next subject.—A. About the cost of cotton culture. Mr. Solon Robinson, whose opinions were unfavorable to slave labor, made a statement of an examination he made in detail of the books of a farmer in the Pedee region of South Carolina in De Bow's Review. His valuation of the capital employed is full, amounting to \$161,000. In this he charges among the running expenses interest at 7 per cent, making the total of the current expenses over \$13,000. The 351,000 pounds of cotton produced cost 4.7 per pound. In the hundreds of recent estimates of the cost of the production of cotton I do not remember to have seen a detailed reliable one as low as this. The cotton sold at 7 cents and the net earnings were 11.6 per cent on the investment, not counting improvements. The price of cotton rose after this, and during the fifties averaged 9½ cents. The running expenses, as far as I can determine, remained the same. Of one thing there can be no doubt—the efficiency of negro labor increased greatly during this period. In 1886 I collected from 12 of the best cotton growers of this region itemized statements of the cost of cotton production. They ranged from 6.1 to 15.22; the average was 8.28. Cotton may grow everywhere between the parallels of 40 north and south latitude. Great efforts were made during the years of our war to develop it in all countries. They were not very successful. Down to 1895 the East Indian crop declined after the price reached 11½ cents, the Brazilian and West Indian after the price fell to 14 cents. Only in Russia, owing to unusual development of agriculture, and in Egypt, owing to the peculiarity of the staple, has production kept up an increase since cotton fell below 11 cents. There can be little doubt that 9 to 11 cents a pound is somewhere close to the margin of safe cost in cotton growing. If it is asked how such large crops have been grown at so much lower prices, the answer is that they have been grown on credit. The credit has been maintained by the sacrifice of other property to maintain the cotton growers. They have reduced their style of living and have abandoned many of their schools, many rural pursuits, and home comforts, to do so. I am told by visitors from other sections that our neighborhood seems exceptionally prosperous in comparison with others; and yet from my piazza I have counted in a radius of 3 or 4 miles 11 houses, once inhabited by substantial and prosperous families, which are now empty or are occupied by negro tenants, the land divided up into small cotton patches cultivated by negroes on the edge of want. Our orchards, our vegetable and flower gardens, our sheep, cattle, and horses, our servants, the repairers of our dwellings, and whatever surplus there was of other securities have all been swept up and consumed in maintaining our credit as cotton growers.

The facts above stated seem to show that the earnings of agriculture compared 40 years ago favorably with investments in other lines. That they may not do so now is owing to the methods by which agriculture is now conducted. My own experience with factory and railroad stocks admonishes me that they also sustain serious and sometimes fatal losses. Of one thing there can be no doubt; the earnings in manufactures are grossly exaggerated in the Census returns. My sons are running a little mill, and I prepared an article from the Census on the comparative profits of agriculture and manufacturing that I will submit, if you care about having it.

Mr. A. L. HARRIS. I think the commission would be very glad to have it. (See Exhibit A.)

The WITNESS. As to taxation of agricultural property, it is much higher than formerly. The revenues of the State, derived largely from such property, are 3 or 4 times as large as they were formerly. As for myself personally, I own one-fourth of the landed estate that belonged to my father, with a very much smaller fraction of personal property than he owned, yet my State and county taxes are 30 per cent higher than his were, and this does not cover the road and poll tax, charged chiefly to laborers. Such a weight of taxation is greater than that which produced the Revolution and greater than the tariff charges to which secession

was attributed. It is endured now because it is distributed among small taxpayers, who do not realize the burden. A charge of \$1 poll tax and of \$1 road tax is collected from a negro who has not a change of clothes, upon the penalty of putting him on the chain gang if it is not paid. The assessment valuation of property is preposterous, unequal, and unjust. When made by local boards of assessors, all sorts of favoritism is shown. Self-government is a very different thing from local self-government. The first kind is promoted by a general government, resting equally on all; the second is administered by narrow-minded, small local authorities. I suggest as a remedy classification of lands and valuation on such classes, no taxation of rural improvements, and taxation of licenses and franchises. A license tax on cotton planting, said to be unconstitutional, collected on the acreage throughout the cotton belt, could be easily and certainly collected, and it would furnish full revenue for State, county, and school needs. It would inhibit excess of expenditure of all our energies in this direction and direct them profitably to other pursuits.

Q. (By Mr. CLARKE.) You say that such a law is said to be unconstitutional. By whom is it so said?—A. By the press. I published an argument in regard to that matter, and the papers came out and said it would be paternal government. I think perhaps the best thing in any government is something prohibitory—like the Ten Commandments—to tell us what not to do. If they should tell us not to plant so much cotton, it would be more in accordance with the Decalogue.

Answer to question No. 29. There is no migration with us except a slow and persistent one to the towns.

Answer to question No. 30. Since the recovery from an inflated war currency, no decline in price of agricultural products has been persistent, except in the case of cotton, due to overproduction. The prices of other products fluctuate, but they average about as they did in the first quarter of the nineteenth century.

Answer to question No. 31. The usual price of average land before the war was about \$10 an acre. Near towns it has risen recently much above that, say to \$30 or \$40 an acre. Remote from towns it has fallen to an equal degree, say to from \$2 to \$3 per acre.

Answer to question No. 32. The decline in the productive condition is due solely to the management. The first settlers generally chose the most fertile lands. Out of 4,000 acres of my estate, about the best 100 acres were of land settled in 1734. There was a large immigration from the Peedee section early in the last century. The lands were thought to be worn-out. They are now, under different management, among the best, if not as a whole the best, in the State. The early settlers abandoned old clearings and made fresh ones in Carolina, not because the lands were worn-out, but because after a few years cultivation was rendered difficult by what was then called "crap," since "crab," grass, which made its appearance in force. The invention of the sweep plow has overcome this invader, and the grass is found to make excellent hay, coming up after small grain and in the corn fields when they are laid by in July.

Answer to question No. 33. The increase of acreage in cultivation in South Carolina is due to the law requiring the fencing in of stock and the punishing of owners who allow their stock to trespass on the unfenced lands of others. The law has removed the expensive burden of fences, but the amount of stock has diminished under its operation, and the destruction of wood lands increased. The fences also act as barriers to the washing of the hills to a certain extent, and their removal has increased the damage from freshets. That is a case in which we all fought very hard for 20 years to get something done, and now the most of us are sorry for it.

Answer to question No. 34. Increased acreage has resulted in increased production, and naturally in lower prices and profits; but by giving employment to more hands it has a tendency to keep wages up.

Answer to question No. 36. We have had a number of agricultural organizations which have sprung up quickly and subsided as rapidly, having no permanent results.

Q. (By Mr. A. L. HARRIS.) Have you any farmers' institutes?—A. Yes; Clemson College gives us farmers' institutes.

Q. You may describe the working of your farmers' institutes, if you will.—A. The neighborhood makes application to the president of the agricultural college for lecturers, stating the subject that the people wish to hear discussed. He sends some of the professors down, and the neighbors all meet and have lectures. I believe that is the usual form of carrying on those institutes. I do not think they are conducted for over 1 or 2 days. Then there are institutes given for a long period of time at the institution itself to which farmers are invited, but the cost of transportation is so great that a great many of them do not go except in the

immediate neighborhood of it. We have had a farmers' institute in our neighborhood, and it was very well attended, a great deal of interest being taken in it.

Q. Does your local talent take part?—A. Yes; the people of the town in which it is held participate.

Q. The college furnishes how many of the lecturers?—A. The college furnishes 1 lecturer only on an occasion. We had 2 or 3 other lecturers, 1 from the agricultural school near by. There were probably 200 persons who attended it.

Q. Is there a growing interest in the farmers' institute work?—A. If they were persistent in it, it would have that result; but they have not been persisted in.

Q. What, in your opinion, would be the effect if persisted in?—A. I think it would be excellent. I do not think anything is more necessary in the rural districts than the lecturers. I do not think anything would arouse more interest in anyway and in every department than the lecturers. They would listen to them when they would not listen to their neighbors.

Q. Would the result be beneficial?—A. Undoubtedly, undoubtedly. Our neighbors are too poor to hire the lyceum lecturers, and if the State would or could secure them it would be a great advantage.

Q. Giving your local talent place in the exercises, does that have a tendency to increase the interest in the locality?—A. It may after a while. We have an agricultural society or farmers' club in my neighborhood, one of the oldest in the United States, founded in 1843. We hold monthly meetings and have held them except for a month or two during the war, and there are only 2 or 3 men that speak. There are 2 or 3 men that speak every time, and we usually have outsiders. The first Saturday in every month we meet. We have a discussion for an hour or two on some topic we had taken up before. We lack the women in the movement. If we had them there might be more interest manifested.

Q. Are these organizations general throughout the State?—A. There are a good many of them in different places; yes. I say this is one of the oldest in the State in continuous existence.

Q. The getting together and the social relations make interesting features, do they not?—A. Yes; that makes it very interesting, and it has kept our neighborhood a very peaceable neighborhood. People have seen that there is no reason why they should be hurt by their neighbors. That is one of the best features of the whole thing.

Q. Do not these meetings have a tendency to remove the irksomeness of farm life?—A. Yes; they are a great relief. We meet at 11 o'clock and discuss until 2 o'clock. We have a steward appointed for each occasion, and he gives us a barbecue of a sheep and a shoat, and sometimes other things. We often have a very pleasant day. It is the fete day of the neighborhood.

Q. (By Mr. CLARKE.) Why do not the women take an interest in it?—A. In 1843 they brought the ladies in, but somehow or other there was some trouble about bonnets and parasols or something of that sort, and it did not work very well.

Q. Mr. Stubbs, of Louisiana, testified that in the highland of the northern portion of that State the farmers and their wives and daughters gathered annually, sometimes oftener, and held somewhat prolonged sessions, discussing all the various phases of their farm life indoors and outdoors, and that the occasions are very profitable as well as enjoyable. Do you see any reason why such meetings could not be held in South Carolina?—A. They have the Richmond County Club across the river in Georgia, which is holding such meetings now. We hope that we are doing something in that line in the school we started recently—in the last 2 years. I collected all the agricultural bulletins for it, and we have at the library there about 1,000 volumes. I have not only collected the agricultural bulletins, but I put them in cases and catalogued them, and I tell the ladies they contain information about bread making and houses, and getting rid of bedbugs and fleas, with natural history; that, indeed, almost anything they want to know can be learned there. They are taking an interest in the library, and I think it is going to have a good influence upon our neighborhood.

Q. Have you any granges in your State?—A. We had them, but they passed away.

Q. Any Farmers' Alliance?—A. We had the Farmers' Alliance, too, and also the granges. There was a whole parcel of gods and goddesses, and I know one lady who objected to joining because the goddesses had all been given out.

Q. A moment ago we were speaking about experiment stations. Is your experiment station well supported?—A. Yes; oh, yes; admirably supported.

Q. Is it doing good work?—A. I think so.

Q. Are there efficient members of the experiment station who lecture at the institutes?—A. Yes; they are the ones that are sent out. I was one of the visitors at the South Carolina experiment station last spring, and the only objection I found was that they did not have a good exhibition of agricultural implements.

I went there to find out about some implements, and they were not there on display.

Q. Would it not be well to have your experiment station experiment on implements there as well as other things?—A. Certainly; but, as I say, that is left out in the Agricultural Department here, and in the experiment station they imitate the Agricultural Department.

Q. Is your agricultural and mechanical college well attended?—A. There are 400 students there, and there have been several hundred refused admission because there was not room for them.

Q. Have you the color line in that institution?—A. The colored institution is at Orangeburg; a somewhat similar institution.

Q. That is supported by the same means?—A. Yes, by the same means; partly by the State, partly by some fund devoted to agriculture by the General Government here—I could not characterize it exactly.

Q. It does not get any part of the land-grant fund?—A. I think it does. I think the land-grant fund is halved between the two.

Q. Is the course prescribed in your agricultural college a good and sufficient course of agriculture for the agriculturists?—A. I think so. I was very much surprised and very much pleased by what I saw at Clemson. They have workshops there and laboratories, and they teach everything—practical chemistry and botany and entomology and electricity and other things, and they turn out, I should say, a No. 1 men from the institution. But at all those institutions they go more into other professions than they do into agriculture. They turn out good electrical engineers who got positions against experts sent here from the North to put up electrical works in connection with the navy-yard down there in Beaufort. They stood examinations and beat them before the Federal board.

Q. Do the graduates from your agricultural college go back to farming as a rule?—A. I think not.

Q. What becomes of them?—A. They go into all sorts of positions where knowledge of chemistry and things of that sort are called for, or go as teachers in schools, or go into electrical plants, or into cotton mills. They go into workshops, rolling mills, and institutions of that sort, where they can get the position of overseers. That is the usual course. There is no use of trying to give an agricultural education unless you do it in the rural school. There you can teach a boy about grafting, and the adaptation and the nature of plants. If you can not teach that in the country, where it is going to be practiced and where it is the bread of life, you can not teach it in the higher institutions. When you get a boy in a higher institution, he turns out to be a professor or something of that sort; he does not want to raise cabbages. I believe that is the usual experience in this country and in Europe.

Answer to question No. 39: Diversification of agricultural industry is beset with great practical difficulties. In the cotton belt everyone, from the banker to the most unskilled field hand, is ready to promote the industry of cotton growing. Anybody starting for the first time at cotton planting will find everything fitted to help him in his undertaking, and, though a wayfarer and a fool, he need not err therein. This is not true if he should undertake in the same locality the culture of any other of the 247 species of the domesticated plants. He would have to search for instructions and try experiments to a greater or less extent, and experiments in agriculture are immensely costly. It cost my father \$15,000 to introduce the imphee sorghum from Natal, South Africa. Much has been expended and lost in efforts to establish the culture of the vine, though there is no doubt that it can be successfully introduced. The diversification most needed is stock raising, for which the meal and hulls of the cotton-seed oil mills, the heavy crops of ensilage that are made from the Southern varieties of tall corn, cow peas, Bermuda and Johnson grass offer special facilities. We have lately, in getting up cotton-seed meal, got one of the best foods for cattle in the world, and I would call attention also to the Bermuda grass and to these new inventions of ensilage and things of that sort. The day before I left home one of my neighbors gave me a statement in regard to Bermuda grass. On 35 acres of swamp land he had maintained 50 head of cattle from May until the last of October last year.

Answer to question No. 40: The introduction of the mower has increased the supply of hay produced, and it is one of the instances where the supply has increased the demand, for forage brings higher prices than formerly. Improved plows and seeders have reduced the cost of production, and improved ginneries have brought the price of ginning and baling cotton from \$5 a bale to 75 cents a bale.

Answer to question No. 41: The extension of foreign markets would increase the demand for corn meal, and if the inhabitants of the world were clad in the

same number of pounds of cotton per person as the population of the United States (who use none too much for health and cleanliness), it would take a world's crop of the staple amounting to 64,000,000 bales annually instead of 16,000,000 bales.

Answer to question No. 43: Cotton was conveyed to market by water transportation more cheaply 50 years ago than it is now transported by steam, and the same is true of corn.

Answer to question No. 44: Much interest is being taken of late in road improvement.

There are 1 or 2 things in regard to cotton to which I would like to call your attention. The first statement that I will make will be in regard to the guesses made here by the Department of Agriculture about the cotton crop. Here is a letter that I have written to Mr. Wilson in regard to that subject, and I believe I will put that in as testimony. (See Exhibit B.)

Q. (By Mr. A. L. HARRIS.) How late is that letter dated?—A. November, 1897; but the same condition exists now as then. Ever since 1880 I have been writing to the various Departments to try and get them to make an enumeration of the cotton gins as a means of determining the amount of the crop. The cotton gin is the place where all the cotton passes. Seed cotton is not stored; it all goes to the ginhouse, and by the 31st day of December 95 per cent of the cotton is ginned, and it can be accurately known what has been done. A guess of the crop can be made all the way along, if they want to keep on making guesses, which, I think, ought not to be allowed. Mr. Hyde's guess is not worth any more than the guess of Dun or Bradstreet, or other people.

If he can state facts, let him state facts, and not guess. Such a course causes speculation in the market. All our people are waiting for the Department report and those guesses encourage speculation. It is certainly nothing more than a guess when you consider that the fluctuations in the market amount to a change frequently of \$32,000,000 of the crop in the hands of the planter. It is a matter worth taking notice of. If he can state there has been so many bales of cotton ginned up to the 1st day of November or the 1st day of October, it is a positive fact, and he can ascertain that fact; there is no doubt about it. I went to the Department yesterday and asked about it. I could not see Mr. Hyde. I have written a great many letters, and I have worked at the problem since 1880 to try to get the Department to pursue the plan suggested, and thus break up speculation to a large extent. The last application I made to the Census Department here they sent it all around and published it in the textile papers of the North and asked their opinion there; instead of sending it to any Southern papers they sent it to the North to know how manufacturers would like the plan, and the result was that they finally got up a defective scale, which I obtained yesterday, only giving a portion of the facts. I offered to write them out a schedule. There is no reason on earth why an enumeration of the cotton product should not be made as fully and as carefully as that of gristmills and flouring mills and sawmills. In those cases they put it all down. They have schedules for all those things, and have had them since 1880; but the whole subject of cotton ginning, which is just as much manufacturing under any definition of manufacturing as anything else, is left out entirely.

Q. You think that your plan would, to some extent at least, steady the prices?—A. Yes; I do not have any doubt of that.

Q. I wish you would take up that subject, if you will, as to what effect the so-called gambling—puts and calls and futures and options—have on the prices of cotton and farm products?—A. I do not know; I think that question has been pretty well argued out. They make out that it steadies prices, but I know when I go to my cotton factor and ask him what the price is he says: "There is going to be an 11,000,000-bale crop this year," or "There is going to be an 8,000,000-bale crop." They get their ideas once a week of how many million bales are going to be made, and those ideas affect prices. The matter is being discussed all the time. The whole thing depends upon the demand and the supply, and I think that this speculation does have a tendency to equalize things generally. I do not believe the difference is as great as it used to be, but the opinion is that it is demoralizing. It is demoralizing to the planter. I met a friend here sometime ago, a cotton planter. I said, "Where are you planting now; where are you renting land and planting this year?" He said, "Wherever I can find a telegraph office."

Q. Is dealing in options detrimental to the producer?—A. It is detrimental because it puts him into a business that he has no business to engage in. That is the chief way in which it is detrimental, I think.

Q. Does it have a serious effect upon prices?—A. I can not say how much it affects prices, but I can say that people are losing more in the South betting on

cotton than they are by producing it. We can not stop them unless we give them more certain information about it. There is no law that can do it.

Q. Does grain and cotton gambling affect the farmer?—A. I can not give any decided opinion on that subject. Gambling is increasing everywhere; there is no question about that. As I came along on the cars the other day I saw negroes sitting out on the side of the road playing cards and gambling, and there have been several murders in our neighborhood about gambling among negroes—a thing they were not in the habit of doing 15 years ago. The people there want anything that can stop gambling and speculation and cause people to go to steady work.

Q. (By Mr. FARQUHAR.) Under the present conditions in the South what is the lowest price that cotton can be made and sold for at a profit?—A. That is a difficult question to answer. In Bulletin No. 33, United States Department of Agriculture, 1896, on pages 258 to 270, there is as complete a summary of that whole subject as could be gotten up at that time, and it is not satisfactory. The point is this: We used to say that cotton was a crop that took the whole year around. We know, now, that that is not a fact. You can work so many days at the cotton crop, and you can not work any more. If a man works the rest of the time profitably he can make cotton much cheaper than he can if he only works his cotton and puts his mules in the stable and lets them eat their heads off, as a good many do. What can be made depends upon the management. The lowest possible cost I can make it is \$5.88 per hundredweight of lint, without any profits whatever; and it is about the same in South Carolina as it is in Texas. The difference between the two States is the use of fertilizer in South Carolina, and the high-priced labor and the high-priced lands in Texas; they about balance each other.

Q. Has the establishment of the hundreds of cotton mills in the cotton belt raised the prices of cotton to the farmers?—A. I think it has.

Q. Giving a better price?—A. I think so.

Q. Can you give an idea of the appreciable price above the old way? How much per cent do you think the advance would be?—A. I think the best plan to determine it is just to look at the prices in Augusta, which is a manufacturing center, and the prices in any other town. I think it makes a difference. Some years ago I sent some cotton to Savannah, and some to Charleston, and some to Augusta, and ordered it sold on the same day, and I came to the conclusion that I got three-quarters of a cent more for the same quality of cotton in Augusta than I did in the exporting towns.

Q. So you have two means now of disposing of your cotton in the South?—A. Yes.

Q. The raw cotton for export and the manufacturing of your cotton and the exporting to foreign markets of the manufactured goods. Then you really, in a measure, double your prices over what it was when you were dealing in nothing at all but the raw cotton?—A. Oh, yes; and all we want is all the people in the world to put on cotton clothes. Then we will have as much as we want to do; and, as I say, it will require 64,000,000 bales to make the world's supply under those circumstances.

Q. Does this disposition of your cotton give an opportunity for you to keep the money in your own district more than you used to? Is there more money in circulation now proportionately than there was 10 or 15 years ago before your cotton mills were established?—A. I do not think the cotton mills have any effect at all. In the immediate neighborhood the truck gardens and such things spring up for the support of factories, but that is comparatively a small thing. No business now in agriculture can be carried on on a large scale without you can produce by the car-load. All fruit growing and all forage growing and everything of that sort has given out except where you can sell in large quantities. It requires a wholesale business.

Q. Have you any idea how much labor enters into the production of your cotton cloth?—A. I made a calculation of 54 per cent of the total cost.

Q. Is it not a fact now that the whole of that 54 per cent is really added activity in your communities? Is not it a new production for them?—A. The 54 per cent you give to labor?

Q. Yes; all that you give to labor.—A. All that is produced is consumed.

Q. Immediately in your own neighborhood?—A. Yes.

Q. Has not that been a great advantage to agriculture in the South?—A. Now, let me qualify that. You pay the negro laborer off Saturday night and he goes to the store and buys many things manufactured outside. The money is spent in the neighborhood but it goes off to other countries in the end. I say since the war started there is more money than there was formerly. The low prices have not made up for the diminution of profit.

Q. Does the establishment of these cotton mills take out of the labor field a great deal of the white labor that used to compete with the black?—A. No; it does not.

Q. Is not the labor of your mills exclusively white?—A. It is.

Q. What occupation did the white laborers have before they went into the mills?—A. It is hard to say what occupation they had. They were managers of little places. The white people were not doing much actual labor themselves. There is perhaps as much planting and hoeing and plowing done by white people now since the mills started, but these other people were owners or overseers or planters, hiring a little piece of land and tilling it by themselves. I do not think the factories have taken away any of the owners. They have taken away the overseers and the like of them.

Q. (By Mr. A. L. HARRIS.) What progress has been made, if any, in the protection of your cotton crop from injurious insects?—A. What the Agricultural Department has done in the matter of paris green has been very effective on the sea islands and the Mississippi bottoms. We do not use it in the uplands. It is not necessary there, as we do not often have insects. There is no other insect that is of much importance in destroying cotton except the boll weevil in Texas, and I believe they have restricted that very well. They have plans for restricting it.

Q. Are you protected by law from the spread of disease among your animals?—A. No. We have very little disease among our animals. I was talking with one of my neighbors the other day, who is about 60 years of age, on that subject. He said he never had lost but 2 animals in his life, and his rule was that whenever an animal looked like it was not good to sell it and buy another one; but we have no particular epidemics among our animals. We have scarcely any animals but mules and horses. Our stock business has fallen to nothing.

Q. Why is that?—A. We had Texas fever and it killed our cattle. My son has sustained a good deal of loss in cattle that have come from unacclimated regions that have been attacked by the Texas fever and killed. The department has done a valuable work in restricting the fever.

Q. Is the law sufficient, in your opinion, if properly executed?—A. I do not know that we have any restrictive laws. There was an old law in Carolina, when we used to breed fine horses, that no man should be allowed to bring a stallion into the State; our stock was considered so much finer than that of the surrounding States. But there are no restrictive laws that I know of in regard to the health of stock or in any other direction. In fact, we are not stock raising, except to a very limited extent.

Q. You spoke of stock raising having gone to nothing. Is that partly on account of devoting your farms to cotton?—A. Yes. I do not have any doubt myself that we shall become in time a great stock-raising people right there in my own section of the country, where sometimes you now have to go 10 miles to get a pound of butter. Immense changes occur in agriculture in that way. I recollect that on a plantation my father made 37,000 bushels of corn before the war. I met a wagon going 10 miles to buy a load of corn here since the war to feed the stock with.

Q. Is that for the best interest of the farmer?—A. Not at all; not at all. You get credit on the cotton, though, and you can not get credit on the corn.

Q. (By Mr. CLARKE.) Is there any lumber interest in your State?—A. Yes; there are some large lumber interests in the southern part of the State. The shipping point is Beaufort, and there are a number of mills cutting lumber there for European shipment.

Q. Are the tracts of lumber owned by farmers or by men owning the mills?—A. Largely by men owning the mills. A man buys up a tract of land very cheaply and cuts the lumber off it. Owners usually first take the turpentine out of the pine, and the Agricultural Department here has shown that the lumber is better after they take it out than it was before, as far as the eximerents have been made. Then they cut down the timber and saw it up and sell it, and much of it is used in the local demand. There has been a considerable business done along what is known as the lower pine belt in Carolina in lumber, the region of country that extends from the Atlantic Coast to the Sabine River in Texas, which is full of lumber men all the way through.

Q. Is there some forestry all over your State?—A. No; our woods are disappearing in the upper country. The chestnut tree has been killed out by an insect, and the remainder is being burned up. We will have to use coal before long even in the country.

Q. Then it may be said that in no section of the State do the farmers as such have a lumber interest?—A. I did a very good business in the '80's selling the railroad wood, but they use coal now. They will not use pine. My father did a

very good business selling lumber, pine wood, to the steamboats on the river. There used to be two boats running daily up and down the Savannah River. There are only two now altogether, which make weekly trips. It was a profitable business to sell fire wood to them in the old days; but all that has come to naught, and the timber is being destroyed gradually.

Q. Has there been any legislation in South Carolina for the protection of forests?—A. I think there are some bills before the legislature; I do not think anything has been done though.

Q. Do you know whether the owners of the large timber tracts exercise any care for the growing of new crops?—A. No; I do not think the slightest care is given to timber anywhere in the State. Now, while we had to make fences, all were jealous of using up their timber, because they knew they would want it for fences; but now you will not find a fence if you drive 100 miles in the country. I presume there is no State in the world, no civilized country, that has as few fences in it as South Carolina. They do not care for the timber any longer.

Q. (By Mr. CLARKE.) Are you familiar with the mineral phosphate industry there?—A. I was at one time, when I was preparing a handbook of the State. I think you will find a very full compilation of the matter, a history of it. With us there has been somewhat of a decline in the industry of recent years, owing to the discovery in Tennessee and the discovery of the Florida phosphates. It is not as big a thing as it was.

Q. It has been a considerable source of wealth to South Carolina, has it not?—A. Oh, yes. The Coosaw Company stock went up at one time from the original par value of \$100 to \$900.

Q. Can you trace any improvement of plantations to the development of that phosphate industry?—A. I think that the whole fertilizer business has been an unmitigated curse to the South.

Q. In the respect that it has supplanted home-thrift methods?—A. Home thrift. Nobody pretends that the application of fertilizers is beneficial after the year in which they are applied, and the people have gone to work and expended some seven or eight million dollars every year in South Carolina for manure that ought to be made at no cost upon the plantations. You feed stock with cotton-seed meal and cotton-seed hull and you get an increase in weight and an increase in quality. You buy your stock at 2 cents and you sell it at 3 and 3½ and then you get 90 per cent of the fertilizing value of the meal, that has already been fed to fatten the stock, for manure. And the complaint is that it is too heavy to haul out.

Q. It is your opinion, then, that South Carolina agriculturally will be improved most by variegated agriculture and more stock raising?—A. Decidedly. I think that is the whole hope of the agriculture in the South, not only of South Carolina, but of the States as far as the Mississippi. When we get to the Mississippi bottoms, Louisiana and those other States are using fertilizers on the sugar-cane fields there now very heavily. Texas uses very little and Mississippi comparatively little. Alabama at one time used none, but is increasing a little. There was not any used in our State before the middle of the fifties—no commercial fertilizers.

Q. Outside of what you call truck farming is there any considerable fruit and forage growing in your State for the Northern markets?—A. Yes; the whole seacoast is engaged in that industry, and in some of the interior sections, too, they make shipments; but it has to be done on a large scale—carload lots. Then there is watermelon growing; we ship a good many watermelons. That is a speculation.

Q. Those are comparatively new sources of wealth for your State, are they not?—A. Yes.

Q. On the whole, are they doing well or ill?—A. Well, upon the whole, the watermelons have been a failure, and so have the cantaloupes that have been raised in the South. Now and then a fellow has struck it, but they complain that the commission merchants in the Northern cities are not reliable; anyhow they often come back on them for rebates for freight in carrying the crop. I think our people are inclined to give the industry up. But, of course, the regular truck gardens on the seacoast are permanent institutions; the owners have their plants well laid out and work very well from Florida to Norfolk, coming in regular rotation.

(Testimony closed.)

EXHIBIT A.—*Relative profits of agriculture and manufactures.*

"Agriculture," says Mr. Higgs in the *New Century Review*, of London, "has been of late a despised industry; intellectual activity has not been brought to bear on it; the men of force and enterprise have failed to recognize that it offers

an absolutely unrivaled sphere for the exercise of personal initiative skill and knowledge. A low type of manhood and a slow unprogressive condition of life are usually regarded as indispensable to agriculture."

Such views prevail widely among the young men of this country. They assert that agriculture is of small importance as compared with the other great factors in the industrial life of this nation. Owning nearly all the land, employing largely more than a third of all the working population, with a costly plant in buildings, fences, implements, machinery, and live stock, the aggregate value produced by the farmers is only about one-fourth of that produced by manufacturers alone, without taking count of the enormous values yielded by trade transportation and miscellaneous industries. Agriculture, they say, is making no progress. In the 20 years from 1870 to 1890 the aggregate value of farm products remained stationary. In manufactures, on the contrary, the values produced were nearly doubled in the 10 years between 1880 and 1890. This explains why active young men are drawn to the centers of manufacture. There they find plenty of work, with a chance every now and then for making a fortune. Your farmer stagnates in enforced idleness when the weather is too dry to plow, and when it is too wet to plow. His chances are a good season every 2 or 3 years. Besides, a young man wants a wife, and young women are getting mortally tired of patching old clothes, making bread, drawing water, and toting wood all in the solitude of the open country. Naturally, they wish to live in a town where there are no old clothes, where the bakers furnish bread ready made, where cheap transportation supplies daily in overflowing abundance every necessary and every luxury of life, where water is drawn from a faucet in every room, where gas and electricity do away with greasy lamps, and social intercourse is not obstructed by distance. Such are some of the inducements that are drawing the bone and sinew of our youth from the farms, and building up the towns and urban pursuits.

The statements above made are open, however, to important corrections. The growth in the value of the products of manufacturers between 1880 and 1890, as shown by the eleventh census, was far from being a real and bone fide growth. The increase was largely due to reporting as "manufactures" many industries not previously included under that head, such as carpentering, blacksmithing, painting, plumbing, coffin making, bottling, hay and straw baling, and many others. In a comparison of agriculture and manufactures, large deductions must be made from the latter on these accounts, as many of these operations and similar ones are carried on by farmers without being enumerated. Cotton ginning will serve as an example.

Other and larger deductions are to be made from the value of manufactured products on account of the duplication of returns. Many manufactured products are used as material for other manufactures and the values returned for each process are counted again and again, instead of simply taking the one value resulting from the whole series of processes, which alone is the true value. Thus the manufacturer who makes a pound of cotton yarn for shirtings returns a product value of 10½ cents. Then another manufacturer takes this pound of yarn and makes with it 3½ yards of seven-eighths shirting value 3½ cents per yard and he reports a product value of 13¼ cents. After this, another man takes this 13¼ cents worth of cloth and makes a shirt with it, selling it for 20 cents, and he reports a product value of 20 cents. Of course, this is the only value resulting from all the processes the cotton has passed through. The enumerators of the census, however, have taken the returns of each as they were separately made, and when these returns are added up at the census office it results that instead of a shirt, value 20 cents, a manufactured product valued at 44 cents is recorded and published for the information and instruction of the public; an overstatement of the value of the manufactured product of 120 per cent.

Other reductions remain to be made. In addition to the plant and the running expenses common to the farmer and the manufacturer, the latter has to pay for his raw material. This additional cost to the manufacturer is estimated in the census returns at considerably over half of the gross value of manufactured products. Now, there is at this time no data to enable us to make an accurate statement as to the values produced by manufacturing. But if we commence, as it seems we must, by halving them, and then taking a large percentage from the remainder, on account of the reduplication of returns, and after that lop off the numerous trimmings, such as painting, bottling, drug grinding, etc., we might well pause lest we should not have enough in hand to procure manufactured coffins to put away the indebtedness left over.

Such considerations enable us in some sort to realize how it happens that many costly factories and many brilliant industrial enterprises fail year after year to declare a dividend, until at last they seem to have lost all notion of legitimate profits and seek to maintain their existence by manipulating the markets with

trusts and booms for stock dividends. It ceases to surprise us that annually on an average 5 to 8 per cent of those engaged in commerce and manufactures go to the wall in utter and total bankruptcy, so that in periods of 12 to 20 years, less than the life of a generation, they are all swept away. Farmers, of course, meet with disasters, but unless they leave their proper work to take a hand at speculation they are never, as a rule, wiped out at one fell swoop. The results of the enumeration of the mortgage indebtedness on farms made at the last census was a great surprise. The unexpectedly small amount of the indebtedness, the regularity with which interest had been paid, and the rapidity of the rate at which the mortgages were being extinguished led up to a settled belief among money lenders that improved rural real estate offers the safest and most profitable security for investments.

Rural life, like life in the cities, has been hitherto too easy to develop the higher energies of man. It is true that few industries remain in a more rudimentary condition than that of tilling the soil. Nevertheless, this very state of things offers greater opportunities to intelligence, industry, and enterprise than are easily to be found in the fierce competition of other crowded pursuits.

Nowhere are there greater possibilities to be found than in agriculture. The truth becomes daily more and more apparent that success here depends more upon the man than it does upon the land. There is a wide future for rural life and its pursuits.

The railroads which have built up their terminals and the towns along their lines have nearly completed the revolution in affairs that was their mission, just as the case has been with sailing vessels and with canals. New inventions are about to usher in a new order of things. The bicycle, the electric car, and the automobile must assuredly again distribute over the open country the human energies which steam has concentrated in the cities.

EXHIBIT B.—*Letter of Mr. Hammond to Secretary Wilson.*

BEECH ISLAND, S. C., November, 1897.

HON. JAMES WILSON,
Secretary of Agriculture, Washington, D. C.

DEAR SIR: I beg leave to submit for your consideration the following suggestions regarding an estimate and count of the cotton crop.

Owing to the fall in the price of cotton of over 30 per cent while the present crop is being picked—a reduction of \$13 a bale, and for a crop of 10,000,000 bales a diminution in value of \$130,000,000—cotton growers are holding back their crops from market. They are doing this at very considerable expense to themselves, allowing the high rate of interest at which they received advances to make their crops to run on, and adding to it heavy charges for storage and insurance. Their action is obstructing business, and all interests in the cotton belt are affected by it. They believe that the crop has been overestimated, and the fluctuations of the market show that uncertainty on this point is general. The present condition is somewhat an extreme one, but similar variations in price, owing, we think, in large measure to uncertain estimates of the crop, prevail every year. The Department of Agriculture gives the average annual range of prices for the years 1891–1895 as 0.21 cent per pound, involving mutations affecting an aggregate value of \$79,500,000.

It would not be difficult or expensive to prepare a township map of the cotton belt, on which was recorded in units of 100 bales the crop grown in each, according to the most accurate enumeration available. On such a map also all the ginneries might be located. With such a chart of cotton production and preparation for market agents of the Department, under its direction and paid for the work, might visit certain townships or portions of townships, and by personal inspection obtain and report to the Department data of almost absolute accuracy.

A visit from the 10th to the 20th of May, would determine the acreage and the character of the stand. Another from the 15th to the 30th of June, would report the growth of the plant, the cultural conditions, etc. Between the middle and the end of July, and also between the middle and the close of August, the count of bolls might be made, and a forecast of the outcome made. The last visit to the fields would be made between the 10th and the 20th of September, to furnish data for a judgment on the top crop. After that data all necessary information should be obtained from the gin houses. The larger part of this could be done by correspondence, but in the beginning personal visits might be necessary. At the outside 8 tours of inspection would suffice. Such inspectors could be readily employed at moderate charges, at the charges at which letter carriers are employed.

Recent tests made by the Postmaster-General shows that a daily house to house delivery of the mail in the rural districts costs from \$22 to \$35 per square mile, averaging \$28. A very thorough personal inspection of the cotton fields should not involve so much labor and time as the rural delivery of the daily mail. But assume that it did, and that the 32,000 square miles of the cotton fields had to be visited 8 times in the year, the statement of cost would stand as follows: As 300 visits for mail delivery is to 8 visits for cotton inspection, so is 32,000 square miles, the area in cotton, multiplied by \$28 the cost of the rural delivery per square mile, to the cost of the inspection of the cotton fields. If this is the proper treatment of the problem the cost of field to field and gin house to gin house inspection of the cotton crop should be \$18,500.

It may be objected that the cotton fields to be traversed by the inspectors, scattered as they are throughout the length and breadth of the cotton belt, are at wider intervals than the houses visited for the delivery of the mail. The most casual examination, however, of an agricultural map of the cotton belt—that, for instance, prepared by Mr. John Hyde for the Eleventh United States Census—will show that the fields producing the bulk of the cotton crop lie in groups, and inspectors informed as to the geography of these groups need lose little time in going from one to another.

Without going into details, the following table, approximately correct, showing the counties growing 98 per cent of the cotton crop of 1889, will make this clear:

State.	Total number of counties.	Counties with 20,000 acres in cotton in 1889.		Counties with less than 20,000 acres in cotton in 1889.		Total number of bales.	Counties planting no cotton.
		Number of counties.	Bales produced.	Number of counties.	Bales produced.		
Texas	244	66	1,125,313	112	315,929	1,471,242	66
Georgia	137	69	972,773	65	219,043	1,191,816	3
Mississippi	74	38	1,110,000	13	44,725	1,154,725	3
Alabama	66	15	829,857	21	85,353	915,210	
South Carolina	35	20	729,604	5	17,586	747,190	
Arkansas	75	45	584,060	30	107,434	691,494	
Louisiana	59	25	553,616	19	105,434	659,180	15
North Carolina	95	21	232,902	61	103,359	336,261	13
Tennessee	96	13	136,868	56	53,711	190,579	27
Total	881	372	6,275,028	382	1,082,674	7,357,697	127

Forty-two per cent of the counties produce 84 per cent of the entire crop; 43 per cent produce only 16 per cent, and 14 per cent of the counties plant no cotton at all. If the minor civil divisions were substituted for the counties, the cotton fields would be found still more closely grouped, and finally large areas of these minor civil divisions would be excluded as not important to the result, thus again reducing the territory to be inspected.

No enumeration of ginhouses of any value has been made for the census. Mr. Edward Atkinson was asked to undertake it at a late date for the census of 1880, and was able to collect no data of importance. The count given in the census of 1890 is too imperfect to merit consideration. Why ginneries have been held of less importance than flour mills, sawmills, grist mills, and a long list of minor industrial establishments it is not possible for me to say. What is noteworthy in the present connection is that the ginhouse is the first and the last and the only place where an accurate count of the cotton crop can be made. While ginned cotton may be stored for months and often for years on plantations and in warehouses, coming to view to swell the size of the crop unexpectedly, unginned cotton is never kept back in this manner.

Ginhouse returns during the picking season would furnish the best basis for forecasts of the crop, and by the 1st of each January the count made there settles the size of the crop for all practical purposes. Ginneries, like most other manufacturing establishments, are being consolidated. The public ginnery is superseding the old plantation ginhouses. They do better work and do it more cheaply. The old cost of ginning a bale was \$5. Now the ginning is done for \$1.50, and the large improved public ginnery is doing it for \$1. The writer has ginned this season 1,145 bales so far for 75 cents. The public ginner has no interest in withholding information as to the number of bales turned out. On the contrary, it is part of his business to know what the small ginhouses in his locality, competing with him, are doing. Unbiased reports should be obtained from him.

This is not the case with the cotton growers who correspond with the Department. Their interest is too great and pressing in the outcome to allow of their forming unprejudiced judgments. Such judgments should be left to the Department of Agriculture and based upon the facts reported by the inspectors. Such facts would be the average number of plants in a given length of row, their average height, the actual count of bolls under definite regulations, etc.

One thing, at least, is certain, State averages of the acreage and condition of the crop, as heretofore published by the Department of Agriculture, furnish no instruction to the great mass of cotton growers for their guidance. State lines are in no way related to the agricultural regions of the cotton belt.

There is a large amount of data on record available for the development and organization of the plan here outlined; but without referring further to it I respectfully ask your consideration for these suggestions on account of the large and important interests involved.

I have the honor to be, very respectfully, your obedient servant,

HARRY HAMMOND.

EXHIBIT C.—*Is the negro a failure?*

BEECH ISLAND, S. C., March 6.

EDITORS AUGUSTA CHRONICLE:

A pressure of farm work has delayed my reply to your circular asking my opinion on an interview with Professor White, published in your paper under the caption "The negro a failure." This is a period of failures, of low prices, of lack of employment, and of diminished profits. If we are to believe the published accounts, this state of things is confined to no locality, or nation or race, but extends over all Christendom, and affects, with great impartiality, all workers and all pursuits. To say at such a time that the negro is a failure does not confer any distinction on him, unless it be intended to mean that the negro, and not "overproduction," or "silver coinage," or "millionaires' speculation and adulteration," or the "protective tariff," or the "war expenditures of Europe," or the "land question," may be the bottom fact responsible for this widespread depression. Perhaps an argument could be made in support of such a theory as ingenious as many of the arguments in support of the numerous and various causes assigned for our distress. It might be shown that workers form barely a third of the population, while the alarm and dissatisfaction of the 17,000,000 counted in this class, in the United States, at being subjected to competition with the 60,000 outcasts in our prisons, prove how very small the number of real producers is; that of these bona fide producers among civilized people the negro must once have formed a considerable part when, after supporting himself, improving his condition, opening fresh fields, and developing the manifold resources of one of the most resourceful sections of the earth, he turned over, almost as a surplus product, to the greatest commercial and manufacturing industries of the world, in cotton, the largest and most important contribution of material ever made to them. It could be shown how in the process of his emancipation the cotton famine came; how, when the supply was renewed, the enormous profits flowing with its current, at first feeble and uncertain, excited a speculative expansion in the vast network of occupations connected with cotton-goods trade that bred a fever in them; how the unlooked-for increase in the production of cotton by the negro fed this fever with a plethora that has been neither assimilated nor excreted until a most damaging and dangerous congestion paralyzes the entire circulation and organism of the world's industries; that even the negro himself is no longer the consumer he was, and notwithstanding its greater cost, his surplus crop has ceased altogether to be such. Through modern mediums of futures and factors, brokers and banks, his cotton crop is now mortgaged, bought, paid for, and sold again before a seed is put into the ground, at a heavy tax on both consumer and producer, yielding to the latter a meager subsistence, with no reserve for investment.

Such an argument, however, would at the outset show that the negro was not essentially and by nature a failure. Nor can anyone acquainted with the record of the negro before or during the late war count him as of no avail. Remember the armies he fed during those 4 years, how his market value had increased 300 per cent between 1845 and 1860, and how in 1848 he made cotton, paying all costs and interest on investment, for 4 $\frac{7}{8}$ cents a pound. (See Solon Robinson in *De Bow's Review*.) To-day, even, with cotton at 7 $\frac{1}{2}$ cents, he earns a living, pays interest on the capital that gives him employment, and has a small cash surplus, which he unfortunately wastes, but which would suffice to insure his life for \$1,000. It would seem to follow that there is no prospect of his extinction or of

his removal from his present field of labor. It has been noted that where the negro forms more than 56 per cent of the population he shows a tendency to decrease, and where he forms less than this percentage he shows a tendency to increase. It is not improbable that there will gradually supervene a general diffusion of the colored race according to some such law as this, and every hindrance to the forces promoting it should be removed.

But if the negro is not a failure, how is the fact to be accounted for that the territory he occupies is far less prosperous than it formerly was?

My answer is that this territory has become involved in profound social and industrial problems touching the relations of labor and capital and the distribution of wages and profits—problems which, in this generation, have become living issues and are being fought out man to man on every square mile of territory from Russia to California. Whoever solves these problems and furnishes a plan on which free labor and free capital may be organized, so as to call out the full activities of each, avoiding injustice and oppression on the one hand and waste and pillage on the other, must abolish labor, as slavery has been abolished, substituting for it work up to the full force and faculty of each man, and will have transcended all previous human achievements. No man will do it. But that faith in human progress, which can never be abandoned, inspires the hope that the people themselves will, in process of time, reach some approximate and practical solution that will put an end to the present turmoil and strife and allow the return of peace, security, and steady work.

Meanwhile we have already advanced far enough in our struggle to review some of the things which have been done and to pass a judgment on them.

The negro should never have been projected into politics, where, without subverting any good end, he enabled, at great cost to himself, the carpetbagger to plunder the community.

The law for collecting liens on crops should be done away with finally and forever in every form and shape. It has substituted an unreal and artificial credit for the proper and natural growth based on character and thrift. It has forcibly dismissed the intelligence of the community from the supervision of its industries. It has seduced workingmen into speculative undertakings resulting for them in bankruptcy, and has delivered them soul and body, by a cheap, summary process, into the hands of the crossroads grocery dealers. It is a legacy of the carpet-bagger that has drained the country of the little he spared.

If we are to have a tenant system, our tenants must have means of their own. It is believed that agricultural depression in England is due to the attempt by tenants to farm with a capital of only \$30 to the acre. Capital is only accumulated by savings, and secure savings banks—postal savings banks, perhaps—would do much to educate and elevate the negro, if he can unlearn the terrible lesson of the Freedman's Saving Bank.

Capitalists must come out from their bombproofs of mortgages, advances, and rack-rents and take their part with workingmen in the risks of the seasons and the markets. Their directing forethought and intelligence are as necessary as they were between 1850 and 1860, when they added so much to the prosperity of the South.

The vast superiority morally and intellectually of the white race must not blind us to certain considerations. This superiority has been the slow growth of untold generations. Among the thousands whose eyes may rest upon this issue of your journal, whatever worthy acts they may perform to preserve and perpetuate this superiority, it is most likely that not one will by word, or deed, or thought advance it one iota. It is not our invention; it is an heirloom of the ages, bringing with it heavy responsibilities. Part of this responsibility is not hastily or carelessly to pass judgment on the other races of God's creation. For this reason it is necessary that men of character and culture should be on duty to control race prejudice, a serious complication in our problem. Where diverse races meet on a common level there is no security, as witness the recent brutal outrages on the Chinese. In such cases it is war to the knife or, what is equally to be deprecated, miscegenation. I invoke no sentimental kindness for the negro; there has been enough of that, and it has been a curse. It is simply necessary to do him justice. So far in the world's history the better class of Southern people alone have done this.

If the present low prices for agricultural products continue, fresh troubles await us. Wages which were fixed in a depreciated currency when prices were high will have to be cut down. That wages should be high when subsistence is cheap is not an anomaly. It occurred in England about the time of the Wat Tyler rebellion, and lasted nearly 2 centuries, with results most prejudicial to agriculture.

But I trespass on your space, and I will conclude by remarking, as to a peasantry, that I know of no record in history where a race of small proprietors have been prosperous. Everywhere they seem to form the wretched residuum of labor after all other occupations are supplied.

Very respectfully,

HARRY HAMMOND.

WASHINGTON, D. C., June 1, 1901.

STATEMENT OF MR. JOHN HYDE,

Statistician of the United States Department of Agriculture.

The Division of Statistics of the Department of Agriculture issues on the 10th of each month (February excepted) a detailed statement relating to the existing agricultural conditions throughout the United States, the data upon which these statements are based being obtained largely through voluntary correspondents. The chief reliance for the ascertainment of conditions is placed upon 3 principal corps of correspondents, namely, county correspondents, township correspondents, and State statistical agents.

County correspondents.—There are in the United States approximately 2,750 counties of agricultural importance. In each of these counties the Department has a principal county correspondent, who maintains an organization of 3 assistants, each covering a specified territory. These county correspondents are selected with exclusive reference to their qualifications, and they constitute a most efficient branch of the crop-reporting service. Facilities are furnished each principal correspondent to enable him to obtain regular reports from his assistants. These reports he tabulates, supplementing the information thus obtained by his own observation and knowledge of the situation, and the consolidated report is transmitted to the Statistician. Although there is no compensation attached to the position, from 80 to 90 per cent of the correspondents report monthly.

Township correspondents.—The list of township correspondents comprises from 6 to 15 individual correspondents in each county. These are distributed geographically throughout the county, the number being dependent on the size of the county and its importance in production. These persons report directly to the Statistician, the schedules for county and township correspondents being tabulated by the clerks in his office.

State statistical agents.—This list embraces a regularly appointed salaried State statistical agent in each of 43 States and Territories, it being the duty of each to report upon agricultural conditions for his own State only. Each of these agents maintains a special list of correspondents, over which he has entire control, completely covering the State and averaging, in total numbers, from 20 to 700 correspondents each, according to the size of the State and its agricultural importance. These State statistical aids report direct to the State agent. Their schedules are carefully tabulated and weighted by him according to the relative importance of each county represented, and the summarized report is submitted to the Statistician on the 7th day of each month. From States west of the Mississippi River the reports of State agents are telegraphed in cipher.

Each of the 3 lists I have mentioned is kept entirely separate and distinct, no one individual being allowed to serve upon any two of the lists.

The reports referred to above are brought together in convenient form on the 8th of each month and the statistician is thus provided with 3 separate estimates, covering the same territory and the same crops, made by separate corps of correspondents, each reporting for a territory with which he is thoroughly familiar, and from these results the statistician compiles his own estimates. The information thus obtained, however, is supplemented by the reports of salaried special field agents, who systematically traverse the producing portions of the country procuring all possible data and carefully analyzing the situation.

Information with regard to final yield per acre is further obtained from reports received from a very large corps of individual producers, each reporting for his own farm only.

The total number of all classes of correspondents in the crop-reporting service aggregates nearly 250,000.

In all tabulations careful attention is paid to the weighting of the figures submitted, so that each county and each State may have its correct and proper influence in the determination of the total for the State or for the United States,

according to its importance. The statistics are compiled with the census figures as a basis, the acreage and production being carried on from year to year by the percentage method.

Correspondents are asked to report in percentages, as compared in the case of acreage or production with that of the preceding year, and in the case of condition with a normal condition. Yield per acre and price per unit of quantity are, of course, reported quantitatively.

With regard to cotton, the information obtained in the manner just described is supplemented by that furnished on special schedules by a list of special cotton correspondents, embracing a very large number of persons intimately concerned in the cotton industry, a complete list of cotton ginneries, and a further list of cotton planters, each reporting for his own plantation. This method of investigating cotton production is, however, employed only for the purpose of making a preliminary statement, the final figures being derived from statistics of movement and consumption obtained from transportation companies, port officials, and mills. This final report can not be completed until after the close of the commercial cotton year—August 31.

Statements relating to live stock and the principal farm crops (except cotton) are made public on the 10th of each month, the cotton statements being issued on the 3d of each month during the growing season. In order that the information contained in these reports may be made available simultaneously throughout the entire United States, and that by reason of quicker mail service the territory adjacent to Washington may not have an advantage over that at a distance, the statements are sent out by telegraph. In order that the figures may be placed within easy reach of the farmer at the earliest possible moment, cards, containing the principal features of the report, are printed and mailed to every postmaster in the United States, within from 4 to 20 hours of the time that the statements are telegraphed, with instructions that they are to be conspicuously posted for the information of the public.

While the necessity of statistics to agriculture is unquestionable, there are far greater difficulties encountered in this application of them than in any other great department of the world's business. These difficulties spring in part from the character of the business itself and in part from its minute subdivision of operations and its wide distribution. That it is far easier to ascertain the output of a group of mines or mills than of a group of farms representing the same value of investment or of product is obvious.

These difficulties are such as can not be overcome by individual effort. It is not easy—it is rarely even practicable—for private initiative to conduct a statistical inquiry in a field so extensive as the United States. The volume of our agriculture, as well as its distribution, is so vast that the most interested private parties can never wholly measure it statistically.

It was perhaps the greater facility with which a complete and fairly accurate knowledge of the operations of large branches of business other than agriculture is obtained that gained for them their far earlier and more adequate recognition in legislation, the collection of agricultural statistics being for many years the work of an obscure section of one branch of a bureau in the Department of the Interior; but a statistical bureau early became a necessity to that large portion of the industrial community represented by the Department of Agriculture. Such a branch of the Department has therefore been in continuous operation since 1863, and it is no disparagement to any other branch of the Department's operations to assert that some of the most general, the most diversified, and in the aggregate the greatest benefits which have accrued to agriculture have been the result of the knowledge obtained and disseminated through this statistical office.

If these benefits are not so direct and apparent as those derived from the investigations of the scientific men who tell the farmer how to suppress the insect enemies that infest his fields and orchards, how to eradicate the various diseases that affect his crops, what are the conditions under which the growth of particular products is most successfully promoted, what fertilizers to use and how to apply them, how the quality of his butter and cheese may be improved, and many other things of high practical value, still they are no less vital and far-reaching, and inevitably tend to increase the rewards of industry by the augmentation of production through the analysis of comparative results, by the maintenance of a reasonable equilibrium between supply and demand, and by contributing to stability of value through the reduction to a minimum of the risks involved in trading.

The American farmer is one of some five million persons who are cultivating our oil, in areas of from 8 acres to well up in the tens of thousands, for subsistence and other profit. Some products he consumes quite largely at home in the main-

tenance of his family and hired help and the keeping and fattening of farm animals. One or more products, however, he annually raises to sell. But all that is raised in one place, whether for farm consumption or for local or distant market, has some relation to all that is raised elsewhere, and it is finally the amount of the supply relative to the extent of the demand which wholly or partially fixes the price and determines the profit or loss.

The all-important problem is how to secure a market, for without a market surplus production above farm consumption is not simply valueless, but positive loss to the extent of its cost.

Statistical information, widely and carefully gathered and properly presented and disseminated, relative to the condition and prospects and in due time to the actual measure of the principal products of agriculture has the strongest influence in maintaining a reasonable equilibrium between production and demand, and the consequent assurance of profit to the producer.

In so far as statistics give timely information to producers of specific conditions affecting the marketing of products, such statistics do all that can be done, and what can not be done in any other way, to secure to agriculture a profit on its productions. It is too much to expect that this result will ever be attained with such efficiency as to leave absolutely nothing to be desired; but so far as it is complete, the benefit secured is due to the statistical method, and will always require its service. What honest producers and interested consumers desire is relations which shall be of mutual benefit, and in the promotion of these relations the Division of Statistics of the Department of Agriculture has not only directly benefited agriculture to an incalculable extent, but, in doing this, has incidentally benefited all legitimate occupations and all consumers.

The benefits conferred upon agriculture by statistics, great as they are, have no more attained their full limits than has agriculture attained its full development. It is not too much to expect that through the gradual utilization of whatever knowledge of physical conditions and of human needs, susceptible of numerical expression, may be available, and the careful setting forth of its precise relation to the great business of agriculture, the statistician of the future will be able to promote the agricultural interests of the country in directions that as yet are hardly dreamed of.

If agricultural statistics are of any value in themselves, their timely availability for the use of those to whom they are of particular interest becomes a matter of importance. They would be of no value to farmers, but might even be positively detrimental to their interests, if possessed by only a few persons or restricted to commercial circles. It is, therefore, the aim of the Division of Statistics in the Department of Agriculture to make the widest possible distribution of the information received through its various agencies, and to make such distribution as prompt and speedy as the necessity of securing reasonable accuracy will admit of. The monthly crop reports of this division are therefore mailed with as little delay as possible to the Department's State statistical agents and the 9,000 persons who report to them, to the 2,700 county correspondents and the 10,800 persons who report to them, to the 40,000 township or district correspondents, to 12,500 cotton planters, to 1,200 newspapers, mostly rural, and to 174,000 other persons, the individual recipients, both correspondents and noncorrespondents, being mainly farmers. These reports relate, according to the season of the year, to the conditions of soil, weather, planting, growth, harvesting, yield, quality, transportation, markets, and prices. They are sent regularly and gratuitously to all persons who have taken the trouble to ask for them, and however susceptible of improvement they may be in any particular respect, the great demand for them leaves little doubt that considerable value is set upon them. When the statistical information received by the Department is made still more reliable by the institution of certain changes in the crop-reporting system, there will surely be no single division of any Government department, and certainly no independent organization, that will be promoting so greatly and so generally the agricultural interests of the country.

WASHINGTON, D. C., February 14, 1901.

TESTIMONY OF MR. WILLIAM BUDGE,*Farmer and Real-Estate Dealer, Grand Forks, N. Dak.*

The commission met at 10.30 a. m., Mr. Farquhar presiding. At that time Mr. William Budge, of Grand Forks, N. Dak., a farmer and real-estate dealer, was introduced as a witness and, being duly sworn, testified as follows:

Q. (By Mr. FARQUHAR.) Will you give your name and your home address?—A. William Budge, Grand Forks, N. Dak.

Mr. FARQUHAR. Governor Harris will conduct the examination.

Q. (By Mr. A. L. HARRIS.) You may state your occupation.—A. I am postmaster at Grand Forks just now. I also run a farm and buy and sell wheat and deal in real estate. I have a farm of my own and have had for the last 24 years.

Q. You conduct that personally?—A. Yes.

Q. Are you connected with your State agricultural college?—A. No, but I am a trustee of the State University of North Dakota.

Q. Have you traveled over your State to some extent?—A. Yes.

Q. Are you conversant with conditions both as to labor and capital?—A. Yes.

Q. You may state in a general way the development of your State.

(The witness then read the following statement:)

"Twenty or 25 years ago North Dakota, then a part of Dakota Territory, was little less than a portion of what was shortly before known as the American Desert. In the western part of what is now the State at that time the Indian and the buffalo roamed at will over a great territory where now are prosperous villages, and where intelligent citizens are tilling the soil, raising stock, mining coal, and engaging in various occupations. A great region, which had been unproductive and which was considered unimportant, has during these few years developed into a great State, rich for agriculture and stock raising, and with many valuable undeveloped mineral resources.

"The great cause of this transformation from a waste and sparsely populated region to a great, productive State is to be found to a large degree in the wonderful developing power of the railroad systems which have passed through and opened up this great territory. When so much is said of arbitrary and unjust acts of railroad corporations, it is only fair to state that it is due to the strong hearts, clear heads, and energetic persons back of these corporations that we have the great development of which the Northwest is so proud. Moreover, these great transportation companies recognize the fact that the welfare of the people is their welfare. In general, I believe that the railroads within the State are doing whatever they feel that they can reasonably afford to do toward developing the country by extending railroad branches, by fostering industries, by affording reasonable shipping facilities, and by granting fair rates of shipment in general.

"To encourage and not to discourage, to enrich and not to impoverish the people is certainly the wish of these companies. Seldom is an urgent need of shipping facilities brought before these companies in a proper light but it is carefully considered. Branches are often operated at little or no profit; side tracks and yards are frequently maintained for sake of convenience and economy to the producer. Rates on the leading products have been steadily reduced until now 8½ cents per bushel will carry wheat from Grand Forks to Duluth, which twenty years ago would have cost 17 or 18 cents. No doubt greater reductions will follow when the railroad companies find that they can afford it and that the general good of the community demands it.

"Increased equipment in cars and locomotives, short lines, and fast trains make it possible to handle the enormous amount of grain on the short notice necessary under the present conditions in this region.

"In order to handle the wheat so that the farmers will not always be at the mercy of the market, some system of storage is necessary to hold the great crops harvested in the fall months. In some cases large farmers or farming corporations have their own grain warehouses. But the average farmer is not able to build warehouses and equip for economical and safe handling of the large amount of grain he produces.

"More than that, only a few are along the railroad lines, and even if they were, of course switch tracks could not be put to each few farms. It is therefore necessary that the farmer should haul in his grain and ship from and through some grain dealer near his farm. So it is evident that the elevator is an essential factor in the grain industry of the Northwest. Of course capital would be invested

in the elevator and grain-shipping business only as a source of profit. And when it is found by operating a system of elevators along a certain railroad that the operating expenses can be reduced and facilities improved, it is only reasonable to expect the consolidation and formation of systems. There is, however, no monopoly, as several companies are generally represented in each town of importance, and the different companies keep a keen watch on the doings of each other. This competition has resulted in reducing elevator charges to reasonable prices for handling and to a uniform basis, the price being 2 cents per bushel.

"No doubt large and influential elevator companies can secure better accommodations for quick shipment when the market justifies, and better prices through their representatives at terminal points, than can individual and small shippers. In this way the farmer will profit to a greater or less degree. It is also certain that the great storage facilities lately being provided by the large elevator companies and the Great Northern Railway will be of much value to the farmers in that they will permit the rapid shipment of grain from the country and will provide sufficient terminal storage, so that the grain can be held for a better market, if thought desirable. This will also be a great relief on the demands for the rolling stock of the railroad during the short period of the grain-shipping season. I firmly believe that the present elevator system is of the greatest value to the agricultural interests.

"River navigation is not developed to any great extent in North Dakota for the reason that there are only 3 rivers of sufficient size within the State to warrant the use of boats. These 3 streams are the Red River of the North and the Missouri River. The navigation is carried on by small flat-bottomed steamers and freight barges.

"For years considerable freight has been carried along these 2 rivers by boat. On the Missouri the freight is of a very diversified nature, that coming in being largely lumber and building material and provisions forwarded from railroads, and that outgoing being largely grain and coal.

"Shipping on the Missouri supplies a large region which has for years been without railroads, and is for that reason the more appreciated. The great impediment to navigation in this river is the shifting sand bars which are formed because of the shallow water and wide banks. As fast as possible the channel should be dredged and provided with a series of pile bars, similar to those already placed in the upper Mississippi, to confine and narrow the stream. With this done there is no reason why the river navigation should not be much expanded and the adjacent country much developed. It would also doubtless prevent much destruction from river flooding.

"Before the railroads reached the Red River Valley there was considerable freight of all kinds carried by boat from Fargo and other points north along the river, but since the railroads have been operating in this section the freight has been reduced to but little else than grain.

"For small miscellaneous freight rail shipments are faster and more convenient. However, boat shipping is important for those towns situated along the river. The following is a statement of the grain handled by the Red River Transportation Company for 6 years ending 1900. This company does about two-thirds of the shipping and a local company the other one-third.

Year of—	Bushels.	Year of—	Bushels.
1895	287, 180	1898	261, 892
1896	445, 167	1899	510, 375
1897	217, 354	1900	276, 977

"What has been said relative to needed improvements on the Missouri River is equally true of the Red River. This is a shallow, rather muddy, stream but one which does not change its channel much. Very little work has been done on this stream. Some bars have been thrown to deepen the channel and this has doubtless aided, in this way, navigation. But a series of bars and locks located at a few points starting near the upper sources of the Red and Red Lake rivers and running to the Canadian line would not only greatly aid navigation, but would enable a sufficient control so as to prevent disastrous floods which occasionally do much damage to crops, lands, and buildings along the lower Red. The locks and bars would serve as regulators and would also aid much in keeping back the waters for a uniform flow. This would also be very valuable as a sanitary precaution, since in the late summer and the fall months the stream is very low and sluggish and seems more charged with impurities.

"Many towns which depend upon the river for their water supply have suffered from this cause. Grand Forks was forced to put in an extensive filtering system for purification. A series of locks and dams would be comparatively inex-

pensive since the river is admirably suited to such control. The banks are generally high enough and the river channel is very narrow. The following figures will show the fluctuation in water in different years and at different times in the year. Much of this could be reduced by the proposed dams and locks.

" RED RIVER OF THE NORTH.

" 1896: Navigation opened April 18; gauge, 14.5. Water reached highest point on gauge May 30, 27. Cause of high water, rainfall. Lowest water September 13, 0.6. Navigation closed November 7.

" 1897: Navigation opened April 11; gauge, 45.2. Highest water, April 10. Cause of high water, snowfall. Lowest water, November 13; gauge, 1.9. Navigation closed November 15.

" 1898: Navigation opened April 15; gauge, 9. Highest water, July 6; gauge, 9.4. Lowest water, November 9; gauge, 0.8. Navigation closed November 8. Precipitation light during winter and summer.

" 1899: Navigation opened April 18; gauge, 15.9; highest water of season. Lowest water, October 1; gauge, 1.2. Navigation closed December 1. Precipitation light during winter and summer.

" 1900: Navigation opened April 11; gauge, 7.7. Highest water of season, October 13; gauge, 11.5. Lowest water of season, July 1; gauge, 1.6. Navigation closed November 13. Precipitation heavy during latter part of season.

" In river transportation the same rates prevail as by rail, but many points are reached by river more easily than can now be done by rail.

" Of course, the principal industry in North Dakota is grain growing. The Red River Valley is justly proud of being known as the Bread Basket of the world. Crops here seldom fail, and even during occasional years of partial drought the moisture-storing capacity and productiveness of the soil and the resisting qualities of the acclimated wheat plant are very remarkable.

" It must not be thought, however, that wheat raising is all that North Dakota is fit for. In the western portion of the State attention is largely given to cattle and sheep. Large ranching is now giving way to a greater number of small ranches. Settlers are rapidly getting stock on their own farms and thus are better fitted for variations of seasons.

" In localities subject to occasional dry seasons flax culture is being successfully started. This crop seems to do well on such lands and affords another means of diversifying. Several oil mills have been started, and this industry and flax culture bid fair to be very important resources.

" It has now been fully demonstrated that the rich, sandy soils of the central portions of the State are well adapted to growing beets rich in sugar. Movements are already on foot to develop this industry and establish sugar factories. The introduction of sugar-beet culture would be doubly helpful, since it would give the farmer another profitable crop and at the same time supply, in the pulp, a good feed for cattle, and it would start manufacturing establishments in an otherwise rural district.

" A few years ago it was not thought that corn could be raised in North Dakota, and so the pork industry has not been started. But little by little the farmers have planted corn, and saved the seed and replanted until the better varieties, having become acclimated, are now doing very well with proper care, and there is every reason to believe that North Dakota will soon multiply many times its pork production.

" A diversity of crop and industries, which have been the great need of North Dakota, is now rapidly coming. With this will also come a much more uniform value of production and a corresponding improvement in the financial condition of the farmer and the merchant. The great transportation companies will also profit by diversified industries, since this condition will insure a more uniform production and shipment, not only for different years, but during different portions of the year.

" One important industry which is just starting and which should be given all the encouragement possible is the mining of lignite coal.

" North Dakota is being very rapidly settled and developed. This growth is now taking place most rapidly in the central portion of the State. A rich farming area is being opened, and branch railroads are pushing out into a previously unoccupied territory. An increase of above 74 per cent in population during the last 10 years is a growth equalled by but very few States or Territories in the Union. The settlers are usually of an excellent character.

" They are industrious and for the most part intelligent. Many were farmers in other parts of the country or Canada. They are rapidly improving their farm

property, and many who have been in the State a few years possess respectable bank accounts.

"In the Red River Valley farm lands have increased in value from \$5 or \$10 to \$20 or \$40 per acre.

"All classes are becoming deeply interested in their individual and social improvement. Towns are putting in electric-light plants and waterworks, public buildings are being erected, and the schools are well supported. Few things point more clearly to the general growth in number, wealth, intelligence, and prosperity than the wonderful increase in the number of children attending the public schools, and especially in the number of young men and women who are attending the institutions of higher education. The university, agricultural college, and normal schools all show a remarkable growth in attendance and in the character of their work. Many of these institutions rank well with those of the older States.

"In conclusion, it may be said that North Dakota has good reason to be pleased at the development which has taken place along all lines during the past 2 years. Such a growth indicates nothing very bad in the industrial conditions found in this region.

"We have escaped many of those social and industrial evils which are met with in some of the older and more thickly populated portions of this and other countries. Our people are successful in securing a good living and in building up good homes. They are prosperous and contented in their occupations and in building up a great Commonwealth."

Q. Will you please state the condition of labor in your State?—A. We have not any labor with us the same as they have in other States; none except the people that own their homes and farms there. The labor that we have to have during the harvest is a floating labor that comes in there on the railroads and stays during the harvest, which lasts about 3 months, and then generally goes back.

Q. Have you hired labor that stays with you during the year?—A. We have, some of us, a few hired men on the big farms; but on farms like mine we keep one man through the year. And a man that has 320 acres generally has his family and takes care of his farm himself until spring comes. He hires 1 man until harvest, and during harvest and threshing he has 2 or 3.

Q. Have you any difficulty in getting help?—A. We had none last year. Last year it was pretty scarce. We had a poor crop. The year before we had more labor than we could take care of. They move from one part of the country to another. Where there is a big demand for labor, where there is a big crop, the railroads move the laborers.

Q. What are the hours of labor?—A. During harvest we commence as soon as we can get out and work until sundown.

Q. During other portions of the year?—A. Oh, they do not work more than 10 hours.

Q. What are the number of days employed in your State?—A. On a farm it is about the whole year. Of course, we do not have as hard labor in the winter as we have in the summer. There is not much to do but take care of the stock.

Q. How do you pay—by the month?—A. We pay by the month.

Q. What do the wages average?—A. In the winter time about \$15, and from the spring to the fall the average is \$22 to \$25 a month.

Q. Is that payment made in cash?—A. Yes.

Q. Have you any tenants who have families and who live on the farms?—A. Yes.

Q. You may state what privileges they have in connection with the house and their wages?—A. They generally have their house and barn, and if the seed is furnished by the landowner they have half the crop. If they furnish the seed they have two-thirds of the crop, and plow the land.

Q. Have you any tenants of that kind who work by the month or by the year?—A. Very few. They all work on shares.

Q. What is the future for a tenant in your State on shares?—A. There are so few of them that they only work until they get a start and then they go out and take up land of their own.

Q. Do they generally become farmers?—A. They generally become farmers on land of their own.

Q. (By Mr. FARQUHAR.) In your State or elsewhere?—A. In our State.

Q. (By Mr. A. L. HARRIS.) What is their condition financially when they start?—A. All went there poor; they had nothing. There were a few people who came with a little money; but if a man had a yoke of cattle and a cow or 2 and a wagon and a little grub, he was considered pretty well fixed in the early days. Of course, we are getting a better class now.

- Q. Have you any immigration?—A. Yes.
- Q. From what countries do they come?—A. From Norway, Sweden, and Germany. We have a few Hollanders, some Russians, Scotch, Irish, a few English and Canadians, and the balance from the States.
- Q. Are they generally an intelligent and desirable class of people?—A. Yes; they are all mighty good people.
- Q. Have you any French Canadians?—A. Yes; we have; and we have some Poles. They are good people, too. We get French Canadians down in Walsh County, and there are a few in Cass County.
- Q. Is there any tendency on the part of your immigrants to colonize to preserve their language?—A. Not a great deal. The Scandinavians have tried to build a Scandinavian school, but the boys all go to the university. One-third the students at our university are Scandinavians now, and we calculate to put in a Scandinavian chair there so as to have no feeling. In other words so that they will feel that we are fair with them. But the Scandinavian boy very seldom studies Scandinavian; some other citizens do. Indeed we have a Scandinavian chair there now, but the Scandinavian professor is not what we would call a first-class Scandinavian teacher. We expect to put one in in the spring to fill that chair.
- Q. What language is taught in your common schools?—A. The English language.
- Q. No demand for foreign languages?—A. No; there are no teachers nor schools except English.
- Q. You say the young Scandinavian prefers to study English?—A. Yes.
- Q. And the American to get some Scandinavian?—A. Some of them do so as to learn to talk with the Scandinavians.
- Q. It is not, then, for the purpose of preserving the language—the original language?—A. No. The Scandinavian naturally feels friendly to his country, but in the little crowd they have of Scandinavians there in the university we can not tell the Scandinavian boys from everybody else.
- Q. You have some settlers from the older States, have you?—A. Yes.
- Q. What class of citizens are they usually?—A. They are good citizens; people who have left their farms; pretty much all farmers.
- Q. Do they generally come to you comparatively poor?—A. Some of them, and some of them have moved out there with some stock and cattle, and they are in better shape than the rest of them. They are moving from the Western country; more of them are coming than ever before. We have had some Dunkards coming there from Pennsylvania; they moved into a settlement by themselves, and they are doing very well.
- Q. Please state whether, in your opinion, your public-school facilities are sufficient.—A. Yes; and we are improving them as fast as we possibly can. Our public schools will compare pretty nearly with those of any State in the Union where there are good settlements. Of course, you know, in the sparsely settled country we have the little cabins, but our system of schools is very good.
- Q. You have free schools?—A. We have the free-school system. The superintendent of public instruction is elected by the people, and the governor is president of the university. We have high schools; they all grade from one to the other.
- Q. What is the condition of your schoolhouses?—A. It is good. We have fine schoolhouses where there has been settlement within the last 15 or 20 years.
- Q. Has there been any effort on the part of the farmers to have branches more in touch with agricultural needs taught in the schools?—A. Not very much; there is some. We have an agricultural college, and a good many farmers' sons go to the college during the winter.
- Q. Is your agricultural college well supported?—A. Yes; the government supports it. There are probably 300 students now.
- Q. What becomes of the graduates or students when they leave the agricultural college?—A. There are a great many young men who have farms who go to the college to study up on farming and to just get an idea of things when they have not much to do in the winter.
- Q. You have a course that permits that?—A. Yes. And then we have higher courses for boys who go through. Men of 18, 20, and 26 go there and take the course on farming, to learn how to keep the grain and so on, and to seed. Some also go to learn how to run threshing machines and so on.
- Q. Does the course touch on every subject that pertains to agriculture?—A. Yes, and stock as well, pretty thoroughly.
- Q. Is there a good technical course?—A. Yes.
- Q. Do the graduates seek other professions after leaving your college?—A. A few of them, yes. There are a few that go to the agricultural college, and from there to the university, and some of them to the University of Minnesota; they scatter all over.

Q. Do some of them become teachers in agricultural colleges in other places?—

A. They are too new for that yet; they have not run it long enough. Our university boys become teachers; they are a little older than the agricultural college boys.

Q. Have you an experiment station in North Dakota?—A. Yes.

Q. (By Mr. FARQUHAR.) Is it the propensity on the part of the graduates of your agricultural college there to seek the professions and complete their education?—A. A great many do.

Q. In colleges?—A. Yes.

Q. And leave the farms?—A. A good many of them.

Q. About what proportion do you think?—A. Well, it would be pretty hard for me to tell you that, because our boys are young. The young boys are the fellows that are trying to get out. The older ones that are there, they simply study for the improvement of their own farms; but the young boys can go there because they can get in when they can not get into a college. They have not had the chance on the prairie. The schools are small and the grade is very low in the agricultural college so as to give those boys a chance. In fact, our university is put down two grades lower than the high school to give those boys a chance. Now, those young boys come in there and they go through the agricultural college, and in a year or two then they go to the higher schools.

Q. They want to become lawyers and doctors and ministers and all that and not return to the farms?—A. A good many of them, yes.

Q. (By Mr. A. L. HARRIS.) Will you please state the efficiency of your experiment station and the work it is doing in a general way? Are they making tests and issuing bulletins for the information of the farmers?—A. Yes; they are doing it right along.

Q. You may state, if you please, the advantage, in your opinion, that the experiment station is to the farmer.—A. During the winter season it is a big advantage to him. He goes there and sees things in a scientific way by which he can benefit on his farm when he goes back.

Q. Is that the experiment station or the agricultural college?—A. They are both together.

Q. Along what lines does your experiment station make tests?—A. On seeds and on stock, I think; everything in the agricultural line.

Q. (By Mr. FARQUHAR. (Soil?—A. Yes; soil.

Q. (By Mr. A. L. HARRIS.) Does it make any tests on fruits?—A. Yes. Of course, our country is not adapted for fruit except small fruits, such as berries, plums, and raspberries, and things of that kind, and crab apples. And there is a hardy apple that they are commencing to set out there now. They are testing those things.

Q. (By Mr. LITCHMAN.) Is there any attempt to cultivate the Baldwin apple in those regions?—A. No; it is too far North. There are fine apples there; they have a good many in the ground, but fruit is pretty hard to take care of, it is so cold.

Q. Does your cold last longer than it does in New England?—A. Yes; it comes along earlier in the fall. It is not as severe as it is in New England; it is a dry cold. When the farmers set out fruit trees they have to protect them, and they shelter them. Timber grows there now, but when I went to South Dakota there were not any trees.

Q. (By Mr. A. L. HARRIS.) Does the Government encourage the growth of the forest?—A. Yes.

Q. Are its efforts bringing good results?—A. Yes. For a long while we had the privilege of taking up a tree claim by planting trees. We undertook to plant the trees in the sod, and we made a poor success of it until the wild sod was cultivated; but after you get it cultivated you can make a tree grow. We have box elders, ash, cottonwood, and elm. You can grow maple, but not very successfully; some evergreens are hard to grow.

Q. Have the experiments progressed so far as to make any improvement on moisture or temperature?—A. It is pretty hard to tell yet. Last year was the driest we have had and, I think, the finest. It seems to me that the climate is improving—that is, we grow stuff we could not grow when we went there, but I think that is on account of the land being cultivated year by year. We are now growing a little corn. We could not grow any when I went there.

Q. Have you farmers' institutes in your State?—A. Yes.

Q. Are they encouraged and well patronized?—A. Yes.

Q. What is discussed in your farmers' institutes?—A. Subjects generally along the line of farming. The president of the agricultural college generally goes out and 1 or 2 of the professors. The president of the Great Northern Railroad goes to a good many of the meetings, and we have a general discussion.

- Q. Are they bringing good results?—A. Yes.
- Q. What subjects are discussed at your institutes?—A. Stock raising and general farming; all subjects for the improvement of farming; benefits that a man derives by knowing how to handle his products and how to raise them.
- Q. Does the local talent participate?—A. Sometimes.
- Q. Do ladies take part in the discussions?—A. Occasionally, but not very often.
- Q. (By Mr. FARQUHAR.) Have you any dairying?—A. Not to amount to very much. They are establishing some dairies now gradually. In the western portion of the State the entire crop is wheat, and in the east where the farmers have been raising wheat and in the middle portion where they are raising flax and mixed crops they are getting some cattle. This later immigration, coming from the older States, is raising stock, and they make pretty fair butter. But the winters are so long that they can hardly get feed enough. That is the trouble.
- Q. What grade of cattle have you?—A. We have Short Horn, Polled Angus, Hereford, and around the towns we get some Jerseys. When we first started in, President J. J. Hill, of the Great Northern Railroad, was very anxious to have people put in stock, and he shipped in quite a number of Polled Angus bulls to the farmers.
- Q. (By Mr. A. L. HARRIS.) What have you to say in regard to the earnings of capital invested in agriculture compared to investments in other lines of business in your State?—A. When you take into consideration the price at which we bought our lands, not counting what they are worth to-day, it does very well. You know lands are going up. But if we consider only what the farmer considers his land worth to-day, it is a different proposition. He bought his land at from \$2.50 to \$5, and now he figures it is worth from \$25 to \$40 an acre; and the taxes levied on our lands are on a valuation of about \$6.50 to \$7 an acre, I think, but, of course, none of us would sell at that price.
- Q. How do you reach your valuation?—A. The assessor values the land and the county commissioners equalize the valuations.
- Q. Are your tax laws satisfactory?—A. Yes, on the whole, they are pretty fair. They have been amended a good many times, and are in pretty fair shape.
- Q. Have you any amendments to suggest?—A. No.
- Q. Is your farm property valued higher than other property?—A. I do not think it is. I would not like to say it is any lower, but the valuation is about fair I should judge.
- Q. (By Mr. LITCHMAN.) You said that the average assessment value is about \$6 an acre?—A. Yes.
- Q. And the average price at which the land is held is at \$25?—A. Yes.
- Q. That would make an assessment of 25 per cent on the market value?—A. Yes.
- Q. Well, does that same ratio of taxation hold for all other property?—A. No.
- Q. Then the farm land is taxed lower than the other property, is it not?—A. Yes; the banks are assessed at the rate of 60 per cent.
- Q. (By Mr. A. L. HARRIS.) Has there been any decline in the price of agricultural products since you have gone into the State?—A. Yes; there has. I have been in the State for 30 years. Then we raised a little oats and we got our own price for it. We had no sale except to people coming in.
- Q. Of the market generally what have you to say?—A. Why, the markets for the last 2 or 3 years have been about the same. The price of wheat has averaged about 60 cents. Some years it has been a little more and some less, but that is about the average.
- Q. It is profitable at that rate to raise it?—A. When a man cultivates his farm right it is.
- Q. Can you give the commission an estimate of the cost of raising an acre of wheat?—A. About \$5 an acre; that would put it on the cars.
- Q. (By Mr. A. L. HARRIS.) What is the average value of an acre of wheat on the cars?—A. It depends on the crop. In years when we have an average crop of 15 or 20 bushels per acre, we can figure about 60 cents a bushel on our wheat. Last year the crop did not average over 10 bushels; it did not average that.
- Q. Taking it one year with another?—A. Oh, it will average 15 bushels; the valley will run over that about 10 to 12 bushels.
- Q. Is there a margin of profit?—A. Yes; my crop has averaged about 20 bushels ever since I have handled the farm.
- Q. Is there any decline in the productive condition of your soil?—A. No; not if it is handled right. The valley is a black loam, with a solid bed of clay underneath—loam of about a foot to a foot and a half thick on top, and heavy clay on the bottom. Of course, when we get outside of the valley we strike a lighter soil.
- Q. Is it easy to maintain the productive condition?—A. Yes.

Q. When it declines, is it easy to recuperate?—A. Yes, 1 year's rest would put it back in shape. Of course, the land there has never been manured any.

Q. (By Mr. FARQUHAR.) Fertilized?—A. I put on fertilizers. I had a piece close to town that I fertilized, and I raised 36 bushels to the acre on it. I had a great crop off it.

Q. Is the improved farming growing in favor?—A. Yes.

Q. And fertilizing and saving manure?—A. A good many do that, and they rest their land. A good many farmers rest one-third of their land and cultivate the other two-thirds, and put that one-third in the next year, get a crop of grain the next year, turn it down, and thus get away with the stubble in the soil and leave it compact for a crop the next year. I can show you in my bag here a sample of wheat off my own last year. [Witness produces bag.] Here is a sample of my own that a gentleman from the agricultural college said would not fill last year. Mr. Holmes was up there, and he told me that it would not fill or be any good, and I did not think it would fill, either. There is the wheat, and I brought it along on purpose to show it to you. You see it is quite well filled.

Q. (By Mr. A. L. HARRIS.) Does rain come early in the season?—A. About the 1st of July. We had no rain on this wheat until about the middle of July. It then got 2 hours' rain on it, and it filled. Now, the land that was alongside of that that was plowed only raised 4 bushels to the acre and was allowed to rest the year before, but this land was plowed down and the stubble turned under, leaving the soil compact, and there is the difference.

Q. Careful farming then, to some extent, will help the farmer out if the elements are against him?—A. Yes.

Q. Then, the time is coming you think when careful management by the farmer will be necessary?—A. Yes.

Q. Is it growing in favor?—A. Yes.

Q. Have you any bonanza farming left in your State?—A. Yes; we have several big farms. The Lamoure farm west of us has, I believe, about 7,000 acres.

Q. What effect do the big farms have upon the general industry of agriculture?—A. They do not help any. I would like to see them all out of the way. They take up a big space and they hurt our school districts. Where there are only a few children in the district it does not make so much difference, but they do no particular benefit to the country. The owners ship in their supplies and ship their wheat out. They also ship their men in and ship them out.

Q. Are those farms divided into sections—I mean, are they divided up for economical cultivation?—A. Yes.

Q. You may describe them, if you will?—A. They run them all in sections. The roads have to be opened up on a section of land as the people demand them, and they just farm a square section. If they can farm it all in one it is a great deal better. If there is a 2 or 3 mile stretch to plow, it all has to be turned at the same time, and it takes up time, and they generally lay out the distance as long as they can.

Q. How is that plowing done?—A. It is done with gang plows and 4 horses or 4 mules to each plow.

Q. How many men does it take to manage a team?—A. One.

Q. How many acres can 1 team plow in a day?—A. About 5; a little over with good soil.

Q. (By Mr. LITCHMAN.) Do they have any gang plows operated by steam?—A. No; they have tried them but they do not work.

Q. Was it done with a long cable pulling the plows along?—A. It was done with a traction engine, but it did not work.

Q. (By Mr. A. L. HARRIS.) Is the plowing done in the fall or in the spring?—A. It is done in the fall. You have got to do it to get your crop in in time.

Q. Do you wait for the frost to get out of the ground in the spring?—A. No; the deeper the frost the better we like it; the moisture supports the crop in the spring.

Q. (By Mr. FARQUHAR.) Your objection to bonanza farming is that it leaves no family settlement on the farm?—A. Yes.

Q. And it is destructive to the schools by making a great place where there are no children for education at all?—A. Yes.

Q. In other words, it is contrary to the American farm life?—A. Yes.

Q. (By Mr. A. L. HARRIS.) Are these large farms under the control of one man?—A. Yes. One man can handle a big farm. You take a man with 4 horses, and 1 man on a farm of that kind can handle 160 acres. No trouble at all; no rocks, no stones. Everything is smooth; it is not like farming down in this country.

Q. Is this man a hired man, usually?—A. Yes.

Q. Is he a single man?—A. He generally is.

Q. A resident of the State?—A. At times he is and sometimes he is not. The big farm owners hire a crew in the spring, and when the farming is done they let

them out, except enough of them to take care of the farm, and one or two men can do this.

Q. Is the hired man married or single?—A. Some of them are married and some of them are single.

Q. Are those big farms profitable to the owners?—A. I think some of them are and some are not. It depends on how they are handled.

Q. Are they run exclusively for the purpose of making money for the owners?—A. Yes; the land has grown in value, and they make their money on land. The Grandin farm and the Dalrymple farm have made money.

Q. In the spring, what is necessary to do before putting in the wheat?—A. Nothing. You just put it in. The land is all ready in the fall.

Q. Then, is it cut with a binder or header?—A. With a binder. Headers we can not use, on account of the moisture. The wheat heats.

Q. You have to shock your wheat?—A. Yes.

Q. When do you thrash it?—A. Out of the shock. Of course, a good many farmers have stacks, but the most of the wheat is thrashed out of the shock.

Q. What are your facilities for thrashing?—A. We get nice thrashing machines. A good machine will run 2,500 to 3,000 bushels a day.

Q. The operator furnishes his own crew?—A. Yes.

Q. And thrashes for so much a bushel?—A. Yes.

Q. Boards his own hands?—A. Boards his own hands.

Q. Takes his kitchen and everything with him?—A. Everything with him.

Q. And his own cook?—A. Yes.

Q. (By Mr. CLARKE.) Where do he and his men lodge?—A. Oh, in the straw stack or the cooking shanty. It is dry there in the fall. We think nothing about that.

Q. (By Mr. A. L. HARRIS.) Have you any organization among your farmers?—A. Not very many; no.

Q. Have you the Grange or the Farmers' Alliance?—A. Both have been wiped out in our country. We did have them, but they went to pieces.

Q. Have you any farmers' clubs?—A. No; very few.

Q. Have you any grain-growers' associations?—A. We have had, but the people do not seem to take much interest in them.

Q. Why did the interest in the organization among farmers decline?—A. It is pretty hard to tell. It first started in our country as the Farmers' Alliance, and then ran into politics and Populism and broke up. That is about the size of it. Our leaders ran it to benefit themselves, and let it go.

Q. Are your farmers diversifying now?—A. They are to some extent.

Q. To what did they confine their efforts formerly?—A. To wheat.

Q. How are they diversifying now?—A. Oh, they are getting some stock, and they have some hogs, and some chickens and turkeys. Some of them are raising a little flax. But as far as vegetables are concerned, we have no market for them. Rates are so high we can not ship them out of the country.

Q. Do you raise corn?—A. We raise a little crop, yes, for stock. A great many of our people have butter to sell in town. We are buying it now ourselves. What we needed before we used to ship in.

Q. What kind of stock do you raise?—A. We are raising pretty much Short Horns. They do well.

Q. Do you have to feed during the winter?—A. Yes.

Q. Is your hay and forage cheap?—A. Yes; except in the Western portion of the State. You know there is a difference in our State. When you get west of Townner, to the mouth of the river west, the cattle take care of themselves. Our State is not like a great many States; there is a difference in climate in different parts of the State.

Q. Do you raise any sheep?—A. Yes; they do very well.

Q. How is the sheep industry, improving or decreasing?—A. It is improving now. It did decrease about 10 years ago, but it has increased lately. A great many put in a pile of sheep in the eastern portion of the State. Then wool went down and they quit, but now they are commencing to start up again.

Q. It is a profitable industry?—A. Yes.

Q. Are you raising horses?—A. Yes; we have a few horses; not quite enough for the country yet, but pretty nearly. We had to ship everything in before.

Q. (By Mr. CLARKE.) What was the cause of going out of the sheep raising?—A. Low price for wool.

Q. What depressed the price of wool?—A. Well, I guess you know about as well as I do. It is pretty hard for me to mention. I suppose the tariff did that; I do not know.

Q. What is the cause of their going into sheep raising then?—A. Wool is going up, and they are getting more for it, and it pays them to handle it.

Q. Can you give about the dates when these changes took place?—A. I suppose it was during the changes of administration.

Q. (By Mr. FARQUHAR.) Changes of administration?—A. Yes.

Q. It was a tariff matter then?—A. Yes.

Q. (By Mr. CLARK.) Is that a good sheep country?—A. Yes.

Q. And it is profitable to raise sheep if wool commands a fair price?—A. Yes.

Q. (By Mr. LITCHMAN.) Is it more profitable to raise them for the wool than for the mutton?—A. Both help.

Q. (By Mr. A. L. HARRIS.) What breed of sheep do you raise?—A. I should judge they were merino. Some of them are not pure, but we have some pretty good stock there. Growers go to different fairs and buy from breeders and put in the flocks.

Q. You speak of fairs. Then you have an agricultural society there?—A. We do not. We had a fair at Grandin last year. We used to have one in the Forks, but it is pretty hard to keep them up. We have these county fairs, and we used to have pretty good fairs. Early in the settlement of the State we had fairs at the Forks, and we had some of the best stock there I ever saw in my life. It came up from Minnesota and Iowa, and the owners wanted to introduce it.

Q. Were the fairs beneficial?—A. Yes.

Q. (By Mr. FARQUHAR.) These fairs, are they for an exhibition of your live stock and farm products?—A. Yes.

Q. Do you have in most of your fairs an exhibition of the trotting ability of the horses?—A. Oh, there is not a great deal of trotting, but you can not get up a fair there unless you have trotting horses. You can not get up a fair and get the crowd to stay without them.

Q. (By Mr. A. L. HARRIS.) What effect has improved machinery had in developing your State?—A. It has done everything. We could not get along without it at all. We could not raise wheat. In fact, we could not settle the country up without it.

Q. Has it removed the drudgery of farm life to some extent?—A. Yes.

Q. Is it unpleasant to farm when you have good improved machinery?—A. No; it is about as easy as most anything you can do now. All the drudgery about the farm is taking care of the barn.

Q. Any disposition on the part of the farmers to leave the farms?—A. No.

Q. Any disposition on the part of the people in the town to go to the farms?—A. Yes; some do.

Q. You think there are more going to the farm than coming away?—A. I think so. It looks that way in our country. Of course, ours is a farming country.

Q. Have you any suggestions to make in regard to maintaining our home markets?—A. Anything we can improve; it is a good thing for the people.

Q. Have you any manufacturing in your State?—A. Very little. We have a woolen mill and a flour mill.

Q. (By Mr. FARQUHAR.) Planing mills?—A. Yes; planing mills, and at Dickinson we have a fair pressed-brick plant, and I think up in Cavalier County we have a cement plant above Milton. The professors in our institutions sent people to take an interest in the clay and cement, and they are putting in a small plant to test it.

Q. (By Mr. A. L. HARRIS.) Have you any factories for manufacturing agricultural machinery or agricultural implements?—A. No; not in our place.

Q. Any woolen mills or flax mills?—A. We have a woolen mill and 2 flax mills.

Q. Are they doing well?—A. Yes.

Q. Do you raise flax?—A. Yes.

Q. Is that profitable?—A. Yes; I think it is the most profitable crop we have raised for years.

Q. Is it hard on your land?—A. It does not seem to be.

Q. How many bushels can you raise to the acre?—A. Ten to 15.

Q. What is that worth a bushel?—A. Last fall it was worth \$1.45 and \$1.00 at the farm.

Q. Is it more profitable than wheat?—A. Yes; it is worth \$1.25 now.

Q. What do you do with the straw?—A. I have not had any use for it except to feed it or burn it. There are no factories there of any kind.

Q. Would a factory be profitable?—A. Yes.

Q. Is it good feed?—A. Yes; in some ways for certain kinds of stock.

Q. Do you thrash it with a machine?—A. Yes; just the same as we thrash wheat.

Q. Do you raise barley?—A. Yes.

Q. Do you get a good yield?—A. The yield ranges from 50 to 70 bushels to the acre.

Q. What is that worth a bushel?—A. Oh, it runs all the way from 18 to 27 cents. The price depends on the quality. Sometimes it goes to 34, but it averages about 20 to 25 cents for good barley. But the farmers do not take care of their barley the same as they do in other countries and they let it get bleached, and, of course, that knocks 2 or 3 cents from the grade of it.

Q. With care it would be a profitable crop?—A. Oh, yes.

Q. Do you raise oats?—A. Yes.

Q. Do you get a good yield?—A. About 50 to 90 bushels to the acre.

Q. Is that hard on the land?—A. No; it is not as hard as wheat. It is the easiest crop we get.

Q. What price do you get?—A. Oats now are worth 25 cents. We had a pretty slim crop last year on account of the dry season. I want to state these are the river counties of North Dakota, not the other counties, that I am speaking of.

Q. About what territory would your statement cover?—A. An area about 60 miles wide and 150 miles long.

Q. What would you say in regard to the western portion of the State?—A. That is where they are raising flax and more diversified crops, taking in beet sugar, and cattle, and so on.

Q. Do you raise any sugar beets in your country?—A. Yes; but our section is not so productive in sugar as that farther west. There is a difference of 4 per cent in favor of those dry north lands; 4 or 5 per cent.

Q. Is it considered a profitable crop in the western portion of the State?—A. Yes.

Q. Is it profitable in your portion of the State?—A. It would be but not as much so as in the west. The beet grows bigger, and there is more starch but not so much sugar in it.

Q. Are your transportation rates satisfactory?—A. We find very much fault with them, but they are getting better all the time. The companies are advancing their roads and they run branches into different localities. People find fault with them, but they seem to be doing as well as they can.

Q. How many roads have you in your State?—A. We have the Northern Pacific, the Great Northern, the Sioux road, and a little piece of the Chicago, Milwaukee and St. Paul. Wherever two roads come together, of course, it is a little better. The rates are no better, only the shippers are more apt to get cars.

Q. What is the rate per 100 pounds from your place to Duluth?—A. Fourteen cents, I think it is, a hundred; about 8 cents, 84 a bushel.

Q. Has there been any decline in the freight rate in the last few years?—A. Yes.

Q. What was it formerly?—A. Eighteen or twenty, seventeen or eighteen. The rate runs right across the river.

Q. Has that decline benefited the farmer?—A. Yes.

Q. Has it added something to the value of his crop?—A. Yes.

Q. What is the condition of your public highways?—A. They are all right at certain seasons of the year. The roads are level and bridges cross all the streams; but it is like every country in that in a heavy rain it cuts up pretty badly. In the fall of the year they are just like paved roads, they are so hard.

Q. How much of the season are they bad?—A. Only in the spring for about 2 or 3 weeks.

Q. At the time the frost is coming out?—A. Yes.

Q. And the balance of the season they are good?—A. Yes.

Q. Have you any material for making macadam?—A. No; very little.

Q. Are your roads graded?—A. They are ditched and graded, and where they are ditched they are supposed to be graded and ditched on each side, every section.

Q. Who makes culverts and builds your bridges?—A. The county builds the bridges where there is a bridge of any size, and the townships put in the culverts.

Q. And the road district does the grading?—A. Yes; farmers do their own grading, and so pay the road tax.

Q. Is the grading done by the tax?—A. It is done by tax, but people have the privilege of doing it by piecework if they prefer.

Q. Is there an improvement in your roads from year to year?—A. Yes.

Q. You may state, if you please, how many elevator companies you have on your railroads?—A. There are not as many as there were. The Peavey Elevator Company is buying up a good many of them. First there were the Brooks Brothers, the Minneapolis and Northern, the Argyle Elevator Company, and the Kenkel, Toodd, and Bettingen, and a great many private elevator lines.

Q. Where is the home office of these companies?—A. In Minneapolis or Duluth.

Q. How many private elevators are there left?—A. There are a few independent elevators here and there through the country.

Q. Are any of these owned by the farmers?—A. Very few. The farmers have built some elevators in partnership among themselves, but they always let them go.

Q. You spoke about there being 6 or 8 elevators in your town originally. By whom were they built?—A. I was in some of them, and they were built by about 4 different companies.

Q. Were any of them built by local capital except your elevator?—A. No; I do not think they were. There are now only 2. The farmers usually ship their wheat from the platforms or sidetracks. Wherever they can get cars they load them.

Q. The farmer has the privilege of loading his own grain?—A. Yes; providing he can get cars.

Q. Does the farmer have an equal privilege with the elevator man in getting cars?—A. Yes; he does in our country. In some places they claim they do not; but they give them a fair show whenever they can.

Q. You think there is no disposition on the part of the railroads to favor the elevator companies?—A. No; not when they can help it. A farmer will probably want a car to ship his grain, and if a rain comes up he wants the car to stand until he can put in his load. I do not know whether they are granting that privilege now or not; it was a great deal of trouble, but they did that to satisfy them. Of course when the wheat all comes into the market at once it is hard to handle.

Q. Which is more profitable, for a farmer to ship his own grain or sell to the elevator?—A. There is a difference of 2 cents in favor of loading.

Q. Is that 2 cents the profit of the local elevator?—A. Yes.

Q. When you sell to the elevator who fixes the grades?—A. The elevator buyer who is hired by the elevator company; generally young men hired by the company to grade the wheat. They are all under bond of these bonding companies to stand up to the grades and weights to the elevator companies. So there is not much chance for them to get away.

Q. Does the manager of the elevator company sometimes determine the grade of the wheat by merely looking at it?—A. He does. That is the only way he can tell, by looking at it or weighing it.

Q. The scale test?—A. Yes.

Q. And if it weighs a certain number of pounds it goes at No. 1 or No. 2?—A. That depends on the color of the wheat. There is nice colored wheat and some of it gets bleached. The inspectors at Duluth and Minneapolis are appointed by the State of Minnesota, and there is a grain commission to which you can appeal from the chief inspector.

Q. Are these men appointed by the governor of Minnesota or by the commission?—A. I think they are appointed by the governor.

Q. Are they under bond?—A. I think so; but the bond does not amount to very much.

Q. Are they appointed on account of their qualifications?—A. They are supposed to be.

Q. Is there any complaint?—A. There was sometime ago. I was one of the complainers myself, but there has been a new board appointed, and there will be a new one appointed this spring.

Q. Do you get the same treatment that a shipper in Minnesota would?—A. I think so. I do not think there is any difference. Up to 3 years ago, if there was a sprinkling of other seeds in the wheat, they did not give you the quality of the wheat, but established a grade by the dirt in it and then docked you for the dirt. In other words, they took from you in 3 ways. They took off for grade and for the dirt. It is wrong, but that is all done away with now.

Q. Do you know whether that same condition prevailed at Minneapolis and St. Paul?—A. There is where it did prevail.

Q. At the mills?—A. That is where it started from. I was buying wheat at the time and shipping in and I had a good deal of trouble of that kind.

Q. What is the difference in price between No. 1 and No. 2 wheat?—A. The millers determine that. There is a difference of 1½ cents and 2 cents, and when you come down to No. 3 there is probably 4 or 5 cents difference.

Q. (By Mr. LITCHMAN.) What is the wheat you have before you—that sample?—A. That will grade Northern. It is hard. It is a little shrunk in the filling; but it will grade Northern anywhere.

Q. (By Mr. FARQUHAR.) No. 1 Northern?—A. Yes. It is a little shrunken; you can see that.

Q. (By Mr. A. L. HARRIS.) If a farmer has a superior quality of wheat, does he get any premium or advance in price?—A. He gets up to No. 1 hard; that is all.

Q. Will the millers at Minneapolis give any advance for superior wheat?—A. They do not; a wheat like that will make just as good flour as the other. They use it for mixing purposes.

Q. (By Mr. FARQUHAR.) Is there any advantage to the individual shipper in shipping on his own account to Minneapolis when he has the best wheat in the market?—A. Yes.

Q. (By Mr. A. L. HARRIS.) When he ships on his own account, does he get fairer treatment at the terminal point?—A. Yes.

Q. Why is that?—A. Occasionally he finds fault with the inspection, but the commission man has nothing to do with the inspection. There are times at Minneapolis when your wheat will sell above the inspection. If you go on the board of trade, you will find there panfuls of the different grades of wheat and the inspector's tab will be on them; if the miller wants your wheat badly and thinks it is above the grade, he will offer a little above the grade price for it.

Q. There is a complaint that farmers suffer by the mixing of the higher with the lower grades to bring up the grade?—A. That is done after the wheat is sold, at St. Paul and Duluth, and not in the country.

Q. Does that practice have any effect on the price of the wheat at the initial point?—A. No; I do not know that it has, except on the wheat they ship out. It is not supposed to have, but it probably does have. You see, farmers will ship in wheat that is shrunken or a little damp, and that wheat is taken into these mixing and drying houses and they run it through the elevators and work it up a grade. That is where they make their money. Of course, the farmer does not get the benefit of that improvement. Many of them put the wheat in the cars when damp, and it will be graded down 2 cents on account of being damp. The mixing house or the elevator men will see that it is a good quality and he will dry it and put it on the market 2 grades higher. The farmer sometimes finds fault with his own carelessness.

Q. When you ship wheat to a terminal point and it has to be stored, it runs this danger of being mixed, does it?—A. No; you get your grade. They give you your grade for so many bushels of wheat and there is no question about it then.

Q. If I consign my wheat and it goes into the elevator in storage, and I sell, do I get the grade I got a certificate for?—A. Yes; or you can hold it there.

Q. Do the elevator companies charge more at some seasons than others for storage?—A. Yes; it depends on the shipments to Europe and the shipments to Duluth. The year before last we carried our wheat there until the 1st of January without any storage fees on it.

Q. What is the storage fee usually?—A. It is one-half cent a month and insurance.

Q. Does the warehouse man do the insuring?—A. Yes.

Q. And pays for it out of the one-half cent?—A. You pay for it, and the rates depend on the length of time you insure it. It is usually not quite three-fourths of a cent per month—it may be a little more. Then there is the commission on the wheat. The commission man gets one-half cent at Duluth and 1 cent in Minneapolis. All of this comes out of the farmer, you know. It does not amount to much, but it is a little, and all that adds to the expense.

Q. Do the farmers store at the local elevator?—A. Yes; a good many of them.

Q. Are the grades preserved when they store there?—A. Yes; just the same. The farmer gets his certificate of storage, and that is all, unless he hires a special bin. Some of the other elevators will give him a special bin for use in loading in and shipping out. Sometimes they have not the bin to spare, but occasionally they do that.

Q. Are the two elevators in your town owned by different companies?—A. Yes.

Q. Do they compete with each other in buying grain?—A. Yes. Of course the price is set.

Q. Who fixes the price?—A. It is generally fixed by the board of trade in Duluth. They get the markets telegraphed every morning.

Q. What has the company that own the elevator to do with fixing the price?—A. Nothing, except to pay the farmer according to the price established, less 2 cents.

Q. Do line elevator men get together and fix the price themselves at any time?—A. I hardly think they do. You can generally sit down and figure from the market report of the board of trade in Duluth by adding 2 cents for the elevator man. Occasionally it is one-half cent advance, but there is generally about 2 cents difference.

Q. Does the price abroad have anything to do with fixing the local price?—A. Exactly as I has in fixing the price of the markets in Duluth. Whatever large demand there is affects the small elevators out through the country.

Q. You feel that the local price is fairly fixed?—A. Yes; according to the freight rates. Of course, you always have to figure them.

Q. Your freight rates are stable now, so they can be easily calculated?—A. Yes.

Q. Is the price of grain at the time the bulk of it is coming in lower or higher than in other periods?—A. In the fall of the year the price is generally the best

when we first start out. In about 6 weeks the market may drop off quite a little, and it may go up. But the countryman generally will not sell when the market goes up; he waits until the market goes down. That is a fact.

Q. (By Mr. A. L. HARRIS.) You think there is no combination anywhere that either raises or lowers the price at the time the bulk of the wheat is coming in; and when they get it into their own hands, control the price?—A. That is a pretty hard thing to say. I could not make that statement. I could not answer that question.

Q. Have you ever seen any indication of that kind?—A. No, except when there is a rush. Then it generally goes down. When there are a great many cars coming into Duluth and landing at Duluth there is a difference.

Q. The irregularity then can always be accounted for?—A. Yes; you can always see it on the market.

Q. (By Mr. FARQUHAR.) Who built the first elevators in your town?—A. The Minneapolis and Northern Company, the Brooks Brothers, and the Pillsbury Elevator Company.

Q. Minneapolis or Duluth interests?—A. Minneapolis.

Q. Who put in the Fairbanks scales there?—A. The elevators.

Q. Did the railroads at any time go into elevator building or the control of the weighing or anything of that kind?—A. No.

Q. (By Mr. A. L. HARRIS.) Are the managers of your 2 elevators citizens of your place?—A. Yes.

Q. Have they always or for several years been?—A. Yes.

Q. They have not been sent there temporarily by the elevator people?—A. No; generally the men that buy the wheat are men that live in the neighborhood.

Q. Do you know whether or not there is a traveling auditor or manager that passes along the line of the road?—A. Yes.

Q. Is he sent out from the terminal point?—A. Yes.

Q. What is his business?—A. He is simply looking after their concerns, looking after the men. The present manager of the Peavey Elevator Company used to buy wheat in our country when he first started in as a boy; and now he is manager of the line. His business is to see that there is not shortage in the elevators and that the boys are doing what is right.

Q. Is there not a feeling on the part of the farmers that the local manager is unfair with them?—A. Sometimes they find fault.

Q. Is that well founded?—A. No. The boys are all under bonds, you know. They have to stand up to the grades and weights or stand the shortage themselves.

Q. They are under bond to the elevator companies?—A. Yes; they are all bonded through the bonding companies.

Q. You said a moment ago that you had 6 or 8 elevators in your town at one time. Was there any pressure brought to bear that caused them to decrease in number?—A. Nothing, except that when the other roads came in (there are 2 mills there) there was no business for the elevators. The side tracks are all around, and the farmer loads his wheat to get that 2 cents extra.

Q. Your 2 are sufficient?—A. Yes; and the 2 mills handle some.

Q. What became of the buildings?—A. They tore them down and moved them away.

Q. If you desired to go into business, could you get a site and build an elevator?—A. I think I could.

Q. And switching facilities?—A. Yes; I am pretty sure I could.

Q. Are your switching privileges at the terminal points satisfactory?—A. They do not charge anything at Duluth for switching. At Minneapolis they charge one-half cent. They charge one-half cent for transferring your wheat to any elevator or mill; in Duluth there are no switching charges.

Q. Have you ever shipped to Chicago?—A. No.

Q. Have you had any experience there?—A. No.

Q. During the time your elevators were passing into the hands of the line elevators, was there any pressure or any combination that forced them to go out of business?—A. No.

Q. They did not put the price of wheat up on the independent elevator?—A. No. The only fellow that put that up was the track buyer, like myself, when I would come in and pick out a few cars. Occasionally we did that, but not very often.

Q. I wish you would state, if you have an opinion, what effect dealing in options and futures has on the price of wheat to the producers?—A. I do not think it hurts it any; sometimes the producer gets the best of it. I know for the last two or three years the producer had the benefit of high-priced wheat, where he would not have it but for the "future" business.

Q. Did the Leiter deal of the spring of 1898 help you?—A. Yes.

Q. Did it afterwards injure you?—A. It did injure some people who had a notion the price was always going to remain high, but the fellow that had good judgment did not get caught.

Q. Did it help the farmers?—A. Some of them.

Q. Was there any complaint on the part of the farmers that wheat went up when they had none to sell?—A. They always find that fault.

Q. If I buy or sell wheat for May delivery, what effect does that have on the price of wheat in May?—A. It might have a little effect; but it takes quite a bunch of wheat either one way or the other to affect the market very much. No local man or small individual affects the market.

Q. If I am able to buy a large amount for May, would that have a tendency to keep up the price?—A. Yes.

Q. If I am able to sell a large amount, what effect would that have?—A. It would depend on whether you had the wheat to deliver and whether the other fellows could make you come up with it or not.

Q. (By Mr. FARQUHAR.) Whether you were short or long?—A. Yes.

Q. (By Mr. LITCHMAN.) Whether Leiter or Armour?—A. Yes.

Q. (By Mr. A. L. HARRIS.) Have you any remedy to suggest for this grievance, if there is one?—A. I have none.

Q. Could it be controlled by law in any way?—A. I do not believe so.

Q. What effect does the sale of millions of bushels of winter wheat in this country have on the price in Liverpool?—A. I do not think it has any, particularly providing the actual wheat is shown to be in the market. It may at a certain time, but, take the price the year round, I think the price is governed by the actual wheat in sight and not on the option wheat.

Q. You think the Liverpool buyer or seller is dealing on the actual wheat and not on the winter wheat?—A. Yes; of course there are a great many speculators just as in this country, but the actual wheat handling depends on the wheat in sight.

Q. Does Chicago or Liverpool fix the price of wheat for the world?—A. I could not say; the markets of the two places are very close together, but I think the place where the wheat is consumed fixes the price.

Q. The terminal point, you think?—A. Yes.

Q. (By Mr. CLARKE.) Do you know what relative quantities of wheat are sold in this country and what sent out of the country?—A. We use a great deal more here than we send out. The surplus is what I figure makes the price to a certain extent. If we did not have any surplus, we would get a better price for our wheat.

Q. Is not the price of the surplus influenced by the quantity retained for home consumption?—A. Yes.

Q. (By Mr. A. L. HARRIS.) What effect, if any, has the monthly crop report upon the price of grain?—A. Wherever it shows an increase or a decrease it changes the prices to a certain extent.

Q. Who is benefited by that?—A. It is pretty hard to tell.

Q. Does it have a tendency to apply the rule of supply and demand?—A. Yes.

Q. And to that extent at least counteracts the effect of gambling?—A. Yes.

Q. You think it is a good thing?—A. Yes.

Q. Have you any pure-food laws in your State?—A. I think we have, but they do not amount to very much, because it is an agricultural State, and we have nothing that comes in there much unless it is butterine, or cottoline, or whatever you call it.

Q. Have you any suggestions to make as to Federal legislation on the subject of pure food?—A. No; I never studied the thing any. I think it would be a pretty good thing if the people knew what they were getting.

Q. You favor the branding of the article to be sold for what it is?—A. Yes.

Q. What have you to say in regard to the introduction of color into oleomargarine to imitate butter, or the introduction of color into poor butter to imitate good butter?—A. It depends on the season of the year. I do not suppose it makes any difference to the butter, providing I know what it is; but there are certain seasons of the year that you can not make yellow butter unless you color it, and there are lots of people opposed to buying butter unless it is colored.

Q. Now, in regard to oleomargarine?—A. I think it should be branded for what it is, and not colored.

Q. (By Mr. CONGER.) Your idea is to make the dealer sell it for what it is, with a regulation sufficient to prevent the coloring?—A. Yes; I would not object to the coloring, provided the people knew what they were getting.

Q. (By Mr. A. L. HARRIS.) If every package was branded would that be sufficient?—A. It should be.

Q. Have you any suggestion to make as to how that should be done?—A. No; I have not paid any attention to it, except what I have seen on this bill that is

before Congress, and I have not noticed it very much. Our people have not much to say about it, because we are not in the butter business; but I think there should be some way provided by which people would know what they are getting.

Q. Have you any laws to prevent the spread of disease among your domestic animals?—A. Yes.

Q. Are they sufficient?—A. I think they are.

Q. Who are they executed by?—A. By the State veterinaries. I think there are 6 or 8 in the State.

Q. If the stock is destroyed, is there any arrangement for payment?—A. Something is paid, but I do not know how much. It is very little. They are supposed to destroy them.

Q. You think State legislation is sufficient?—A. I think so.

Q. You would not advise Federal legislation along that line?—A. I do not believe I would. Still, it would be a good thing if it could be made the same in all States.

Q. Have you any law to prevent the spread of disease among plants?—A. I think not.

Q. Have you any insects injurious to your trees?—A. We had last year; we had caterpillars. They came out of a shell and spread from tree to tree with a sort of a cobweb, and ate the leaves off all over the country. Four or 5 years ago we had a black caterpillar that attacked the elm tree; but they are all gone, and I have not seen any lately. It was a caterpillar about 2 inches long, a black fellow.

Q. Was there any effort made to destroy them?—A. We did make an effort with the black caterpillar. We burnt them in the trees and in town; and last year there were a great many of the trees, particularly the box-elder trees, that were attacked. We sprayed them with different mixtures, but the spraying did not seem to do much good. The leaves came off pretty nearly all of them, but they all budded out again in the fall.

Q. (By Mr. CLARKE.) Did not hurt the tree?—A. It set them back that year in growth, but they came out again.

Q. Have you any suggestion to make as to better legislation along that line?—

A. I would rather somebody else would do that; someone better informed than I am on these things.

(Testimony closed.)

WASHINGTON, D. C., March 12, 1901.

TESTIMONY OF MR. MILTON WHITNEY,

Chief, Division of Soils, Department of Agriculture, Washington, D. C.

The commission met at 10.37 a. m., Mr. Phillips presiding. At that time Mr. Milton Whitney was introduced as a witness, and, being first duly sworn, testified as follows:

Q. (By Mr. CLARKE.) Will you please give your name and post-office address, and also state your official position?—A. Milton Whitney, Takoma Park, D. C. I am Chief of the Division of Soils, Department of Agriculture.

Q. How long have you been in your present position?—A. About 6 years.

Q. Had you, before coming to that position, been engaged in studies like those you now pursue?—A. Yes; I have been engaged in the study of soils for the past 18 years.

Q. In how many States?—A. I began in Connecticut at the Connecticut Experiment Station, and was then in North Carolina as superintendent at the experiment farm; then as professor of agriculture in the University of South Carolina; then as professor of soil physics in the Agricultural College of Maryland.

Q. Of what State are you a native?—A. Maryland.

Q. The commission will be pleased to have you proceed in your own way to describe the character of your work in the Department of Agriculture, and especially as to how you gather the soils and how you make your experiments.—A. My understanding was that the main question which would come up would be the very important subject of the exhaustion of soils and abandonment of lands, particularly with reference to the New England States and the Southern States, and incidentally the abandonment of certain lands in the West; to see if cause or causes could be assigned, and if there were any suggestions for remedial measures.

Q. Proceed, if you please, in your own way, then, to develop that particular subject.—A. In thinking over the matter, it seemed to me that the subject of the

abandonment of lands is one of great importance in the country, one that has attracted a great deal of attention, and one that is of considerable economic importance.

It is doubtless well known to the commission that there are large areas of land in the New England States that have been abandoned; that there are large areas in the Southern States that have also been practically abandoned and given over to waste; furthermore, that there are large areas in the far West which have once been settled and which have since been abandoned or are now held in very low esteem.

The cause of the deterioration of the lands in the South has been commonly ascribed to the exhaustion of the soil; and this is the first consideration that I wish to take up. The exhaustion of the soil is due, in my opinion, to changes in the chemical and physical properties of the soil rather than to any actual extraction of plant food.

A soil, to be productive, must render annually, as the crop needs it, a sufficient amount of food material in a form available to the plants. As a matter of fact soil is a difficultly soluble substance, composed mostly of silicates and aluminates, or difficultly soluble compounds of silica, alumina, potash, soda, and lime in various forms. Through atmospheric agencies, largely, these compounds are rendered more or less soluble and more or less readily available to plants.

A fertile soil is one in which the weathering effects come in at such times and to such an extent as to render available to plants a sufficient amount of this plant food. If that weathering does not take place and the food material is not brought into a condition in which it is available to the plants, the land is as poor as though it actually contained no plant food.

I have never in my experience seen a case in which one could say with any degree of certainty or even of probability that exhaustion was due to the actual removal of plant food. It is perfectly safe to say that the condition of the so-called worn-out soils in the South is due, not to an actual extraction of plant food, but to the chemical condition in which it now is, in which it is unavailable to plants, and that the restoration of the fertility of that land must be, not necessarily in the addition of plant food to the soil, but in bringing about such changes in the physical conditions or in the chemical combinations as will encourage that natural weathering of the soil which brings the plant food into a condition in which the plant can get its support.

To emphasize this statement, which may appear at variance with the general ideas concerning the exhaustion of soils, I would call the commission's attention to the many cases in which soils have been cultivated for hundreds and thousands of years. So far as we know, within historic times they have been constantly cultivated, and cultivated in the same crops. We have the case of the soils of India, which traditions say have been cultivated for 2,000 years, under primitive methods, without artificial fertilizing, and which still give fair returns of the common crops of the country. We have the case also in Egypt of lands which have been cultivated since history began and where the soils are as fertile as ever. We have all through the southern countries of Europe, and still later in the countries in the north of Europe, in Holland, in Denmark, in France, in England, records of the continuous and profitable cultivation of soils for 500 years—away back to the time when history first opens up our knowledge of these countries.

There is one phase, however, that it would be well to dilate upon here, namely, that with our increase in density of population and with the competition that has been going on, we are no longer satisfied with the yields that are naturally obtained from many of our soils, and we have resorted to the practice of fertilization in order to force plants and produce far beyond what the natural fertility of the soil will give.

There are historic experiments that have been going on in England for the past 50 years, in which a crop of wheat has been grown continuously without fertilization, and the yield has steadily fallen from what it was at first (I forget the figure), until it now produces about 12 or 13 bushels per acre. For the past 20 years there has been little or no difference in the yield, except slight fluctuations due to seasonal conditions, and it is believed that the yield that is now obtained measures approximately the power of the soil to produce a crop under perfectly natural conditions. It will produce annually, so far as we know, for hundreds of years, 12 or 13 bushels per acre.

Q. Are you able to state whether the kernel is as full and well developed now as it was in the earlier conditions?—A. So far as we know, the grain is of the same value, pound for pound, but not being satisfied with a yield of 12 or 13 bushels per acre they have, by the use of fertilizers and manures, increased the yield on adjacent plots to an average of about 30 bushels per acre. In this forcing of the crop they have found that they could economically increase the production from that

soil. The first we would call the natural fertility, and the second the acquired fertility. One is perfectly justified in recognizing these two characteristics in the production of the soil: What it will naturally produce through a course of years under the natural weathering of the material, and what it can be made to produce by the artificial application of more food material than the plant can secure through the natural weathering. If the natural yield from a soil becomes so low as to make it unprofitable, it may often be necessary to fertilize in order to make the soil productive.

The second cause of the abandonment of soils arises from the development of new areas and new industries. There is no question that the opening up of the western country, the great corn and wheat producing States of the central West, the wheat lands of California and of the Red River Valley of Minnesota and Dakota has had a great influence upon the agriculture of New England and all our Eastern States, and has done much toward bringing about the conditions that are now prevalent. This will be taken up more in detail later.

In the line of the introduction of new industries, I would cite the case of tobacco: Before the war tobacco was grown very generally in the State of Maryland, and since the war it has been grown extensively in the southern counties only, but with the introduction of the White Burley tobacco in Ohio and Kentucky—which produces a large yield and which can be produced with profit at a comparatively low price—the tobacco industry in Maryland has been largely given up, and the effect of this change on the farmers of Maryland has been very disastrous, because tobacco has been one of the staple products of that portion of the State.

Another instance that I should cite is the development of the truck industry. Fifteen or 20 years ago the truck industry was in a very flourishing condition in Maryland. Truck was grown very extensively on certain classes of soil which were not adapted to other lines, and there were certain localities in which the people were extremely prosperous. But with the development of transportation facilities, with the opening up of truck areas in the South, in South Carolina and in Florida, and with the production of those early vegetables which could be rushed up to the Northern markets in the winter and early spring, the industry has languished in certain localities to such an extent that it has been given up. That is the cause of the abandonment of farms in certain sections of the Atlantic coast States.

Q. (By Mr. KENNEDY.) Are you going to discuss the question of irrigation; whether it will have a still further effect to cause abandonment of poorer lands?—

A. I will speak later of the West, but I will bring this in at this time, though I was going to speak of that particularly in connection with the New England States.

Q. You had better take your own order probably.—A. I will be glad to answer any particular question as we go along, though.

Another very important contributing cause to the abandonment of lands has been in the unfortunate ventures that have been made in bringing a people from a distance to settle a region with which they are unfamiliar, and to grow crops with which they are themselves acquainted in the localities from which they come, but which they have no appreciation of as adapted to the localities into which they are going. The Department of Agriculture is constantly in receipt of requests for information as to where certain settlements of people could be made—people who are to be brought in to grow alfalfa, to grow stock, to grow tobacco, or other crops. And very frequently the utmost ignorance is shown as to the localities which are to be selected and as to the conditions into which they are going.

There have been many instances of failure from these causes alone in the States of Maryland, Virginia, Pennsylvania, and in fact throughout the country.

One instance I would speak of particularly, that has come to my personal attention, is a settlement in one of the Western States. A large area of land was taken up and put under irrigation. Agents were sent from this country abroad to attract immigration. People were brought from Switzerland, from France, from Germany, and an extensive plan of development was outlined. They were to introduce the European grapes; they were to introduce and develop the sugar-beet industry; they were to take up all kinds of fruits that had been successful in their own districts; they were to grow truck crops, and they were to develop large grain and cattle interests. But the plans completely failed, as their soils and their water and their climate were not fit for the industries that they started. After a most disastrous and expensive experience they have lost their crops; they have found that fruit will not grow; that the grape is not suited to the conditions there. They have lost their money, and they have come to a realization of the fact that the country and the conditions are adapted simply to grazing; that if they grow alfalfa and stock they can do well, but they can not do well with their fruits and with their sugar beets, because the conditions there are not adapted to those crops.

Q. Would you state what the location is?—A. It is an area in New Mexico that I am referring to. It is an experience in the Pecos Valley. The principal reason for the failure in that case is due to the condition of the irrigation water. It is very alkaline, which these people did not know when they went into that region. Their failure was also due to their unfamiliarity with the conditions in that locality, and their attempt to grow something that they had grown in Switzerland or in Holland under conditions which were entirely different. In an arid region, where they have to use water to produce any crop, the only available water has been found to be unfit at times for irrigation. This is a cause of the abandonment of large areas of land not only in New Mexico but in other portions of the West.

Another contributing cause of the abandonment of lands has been in the selection of localities in which there are unfavorable climatic conditions. The commission is doubtless aware of the conditions in Kansas and in portions of Nebraska and of Colorado; how, during the boom times of 15 or 20 years ago the country was settled, towns were established, and farms were obtained with the idea that fortunes could be made on the agricultural products of the country. Cotton mills were put up out in the semiarid regions, and are still standing as monuments to the unfortunate schemes and ventures that were devised.

Q. (By Mr. CLARKE.) Could you state what the cause of failure was in that section?—A. Yes; I will come to that.

Q. (By Mr. KENNEDY.) You do not mean cotton mills in Kansas and Nebraska?—A. Yes; there are abandoned cotton mills in Kansas and Nebraska.

Mr. TOMPKINS. There is one at Kearney, I think.

The WITNESS. In explanation of the conditions just stated, it may be observed that the semiarid region of the country extends generally from the 100th meridian to the foot of the Rocky Mountains, and embraces in my definition such areas as have from 15 to 20 inches of rainfall per year, but so distributed that only occasionally are the seasonal conditions favorable for crops. When they have a favorable season, or two in succession, as they frequently do, they get fine yields and make good returns, but in 3 years out of 5, when they have their disastrous droughts and get nothing, the profits of the 2 successful years are entirely used up.

With less than 15 inches of annual rainfall lands are seldom or never successfully cultivated, so far as I know, except in certain areas in Washington and California. With 20 inches of rainfall (that is half what we have in the East), provided it is fairly well distributed, good crops can be grown in the semiarid regions; but it is the uncertainty of the seasons which renders farming unprofitable. It is the uncertain and unequal distribution of the rainfall that has caused so many disasters and has been the reason of the abandonment of so many farms.

It is perhaps one of the most serious problems, that of the semiarid regions, that we have in the agriculture of this country at the present time. In the far West such conditions can be overcome where irrigation is practicable, but so far as known there is no bright future for irrigation in much of the semiarid regions of the country. In Kansas there were in 1889 only 20,000 acres of land under irrigation. In North Dakota, South Dakota, Nebraska, Kansas, and Texas there were only 67,000 acres of land under irrigation in that year, and the possibilities of getting water are small in comparison with the vast areas that would need to be watered to be permanently and safely productive.

Another cause that has contributed to the abandonment of lands in the semiarid regions has been the deterioration of the ranges and the consequent injury to the cattle industry. I hardly feel competent myself to speak on this subject, as we have a division in the Department of Agriculture which is giving its attention to the investigation of the range problem and the possibilities of conserving and maintaining the ranges. Being a question which is at present under discussion by the Department, it would hardly be proper for me to go more at length into it. It seems to me, however, that it will be necessary and wise to adopt some legislation to protect the ranges in the West, and to prevent the terrible destruction of property which is going on through close grazing, against which there is no restriction in many of the areas of the West. It seems to me that this is a problem for legislation, as it is at present too difficult for the agriculturist to deal with and much of it occurs upon the public domain. Where range lands are rented for 5 cents an acre little expense can be put upon them for their improvement. There is little chance at present to make any improvement in the agricultural conditions where land is so cheaply rented, so cheaply purchased, and so carelessly used.

Another example of unfavorable climatic conditions may be cited in the Connecticut Valley, right here in our Eastern States. With a rainfall of about 40 or 50 inches, we have soils that have been abandoned from the same unfavorable

climatic conditions—a deficiency of rainfall—as prevail in the semiarid regions of the West. I refer particularly to the Windsor sand, which occasionally produces a very fine crop of tobacco, but the soil is so coarse and leachy that it is only about 2 years out of 5 that the conditions are favorable. In the favorable years they get good yields and the farmers are very prosperous and contented; in the other 3 years out of 5, as in the West, the soils dry out and are subject to such disastrous droughts that they are entirely unproductive. The expectation of getting a crop even 2 years out of 5 has induced many farmers to hold on until finally there have been successive seasons of failure, and they have had to give up. Under conditions of well-distributed rainfall the soil produces, as does the semiarid land in the West, but it is a desert for 3 years out of 5.

Q. (By Mr. PHILLIPS.) About how extensive is that area?—A. The area in the Connecticut Valley is not large, but along the Atlantic seaboard, in the aggregate, it covers a large area. These coarse, sandy soils are found from the New England States all the way along the Atlantic seaboard and around the Gulf, and many farms have been abandoned on these areas simply because of the unfavorable climatic conditions for these particular soils when other soils surrounding them are favored by the same conditions.

I would cite also another instance to show the effect of unfavorable climatic conditions on the abandonment of soils, namely, the orange industry in Florida, where they have grown oranges with great success for years and where the industry has flourished in the most promising way until a season of frost and freezes that has thrown back the industry for years and has ruined a large number of people. This is a contributing cause to the abandonment of lands, which can not be overlooked in the consideration of the subject.

Another cause for the abandonment of lands is found in the scarcity of water in our desert countries. The public lands of the arid States amount to 560,000,000 acres. Only 3,600,000 acres were irrigated in those States in 1889 and only 74,000,000 acres are capable of being irrigated, according to the most careful estimates of the Geological Survey. We have, then, the difference between the possibilities of 74,000,000 acres and the actual extent of 560,000,000 acres, which are used to some extent for grazing lands, and upon which living is, at the most, extremely precarious. Many areas have been abandoned which have once been settled, simply because of the extreme scarcity of water and the impossibility of producing agricultural crops or promoting agricultural interests.

Another important cause of the abandonment of lands is found in the alkali and seepage waters of the West.

I would call the attention of the commission to some work the Department is doing in Salt Lake County, Utah. This was one of the earliest settlements where irrigation was tried in our modern civilization of this country. When the Mormons first settled the place they naturally took up the richest bottom soils along the Jordan River. The soils were naturally filled with salts, but with the drainage that was started and from the character of the soils themselves the salts were quickly removed and the lands were in splendid condition for agricultural use.

In the further settlement of the country, in the increase in the density of population, as the settlers moved up on the high lands and the water was applied at higher elevations, the seepage of water from the canals accumulated in the low places and brought with it the salts, which accumulated to such an extent in the low places that the first lands, the most fertile lands of the valley, were rendered entirely unfit for cultivation. They were wet and swampy, and they were filled with alkali, and the history of this once prosperous community has been that the people are moving up onto the bench land, and are abandoning soils which were once the most productive in the State.

In the area which we surveyed in Salt Lake County, between the Jordan River and the Great Salt Lake, about 50 square miles of land has been successfully cultivated under irrigation. Of this, 10 square miles, or nearly one-fifth of the whole area, has been ruined and has been abandoned as worthless and useless, and the injury is progressing. Lands are constantly being turned out which have been swamped with seepage waters and which have been filled with alkali.

This is one of the most interesting and most important problems of the West, and one which I should like particularly to bring to the attention of the commission, because it seems to me that something will have to be done through either State or national legislation to stop the injury that is going on.

Q. Have you any theory as to how to stop it?—A. I will go on to state that. The conditions may be briefly stated thus: The canal company, whether organized by the farmers or organized with independent capital, constructs a canal and maintains a certain level or uniform grade, going through all kinds of soils which it may be necessary to go through in the construction of its canal. It happens in the Salt Lake Valley, as in many other localities that we have studied, that this

canal goes for several miles through a gravelly soil, in which there is a great deal of seepage and loss of water. The water is plentiful and of good quality, so the canal companies are not concerned with the loss. They have a bounteous supply from the Utah lake, and they are getting good water, free from alkali. But the water in seeping out through this gravelly area is slowly filtering through the soil, carrying with it a relatively large quantity of salts, which are in all arid soils, and are concentrating the salts in the lower lands and are filling up the lowlands with water, until, as a matter of fact, there is a string of lakes out in what was once an arid, desert country—artificial lakes on what were later fertile and well-cultivated soils, and which are now abandoned lands and tule swamps.

It seems to me that the farmers situated on those lower levels should have recourse, through civil suits, to damages, and the canal companies maintaining canals under such conditions should either be compelled to protect their canals from seepage or to pay damages to the farmers whose lands are ruined.

These conditions are exceedingly pernicious. If you have a soil under the most careful methods of cultivation, farmed with the most expensive varieties of fruit or other farm products, taking the utmost care, giving the greatest attention to all methods of growth so far as your experience and your skill or the knowledge of your experts will indicate, it is certainly most exasperating to have the land swamped and filled with alkali from a leaking ditch situated perhaps 3 or 4 miles away, and over which you have no possible control. It is an exceedingly pernicious thing, for which some recourse should be had in damages. But, so far as I know, there is nothing to stop it. The lands are going to waste, and one-fifth of the irrigated lands of that district alone have been abandoned from this cause—a cause which could have been provided against. These lands could have been protected and these farms could have been saved.

Another instance that I would cite in connection with this district is the extensive area that is situated just west of Salt Lake City and extending over to the Great Salt Lake. There is an area of about 90,000 acres, and it comes close up to the Jordan River and extends across to the Salt Lake. The land is filled with alkali, but it is not always apparent on the surface. Frequently the surface looks like a fertile, easily cultivated loam, and many attempts have been made to settle the country. Many farms have been laid out, canals have been constructed, water has been let on to the places, town sites have been located, railroads have been projected and built, and with the first application of water good crops have been produced; with the second, a failure. With the third application the land has become so salty that it is abandoned as a waste and desert land. Thousands of dollars have been invested in the settlement of that tract, and thousands and thousands of dollars have been lost in the fruitless effort to build up an agricultural industry in that area, and this is the cause of the abandonment of these soils—because of the occurrence of alkali not always seen from the surface, but always lying in the lower depths of the soil ready to come up at the first application of water. It will be interesting to state that the result of our soil survey convinced us that it was perfectly feasible to reclaim these lands. There is sufficient fall to put in a drainage system. The soils are naturally easily worked. The expense would be no greater than the drainage of lands in Ohio and Illinois, and the profit that would be realized from the reclamation of the 60,000 acres of land situated on that tract would amount, in our opinion, to about \$3,000,000 in property valuation. Now, a very singular thing has arisen in regard to that section, that while the people seem to realize that drainage may reclaim the lands, yet they seem to be averse to having the drainage work done, and the people who have desired to follow our advice have been unable, in certain cases at any rate, to do so from the objection of their neighbors. There are no drainage laws, as there are in Illinois and in others of our Middle States, and the enterprise is stopped right here by the inability to have any recourse to State laws, and by the unwillingness of the people to give access to the drainage canals through their places. This is a matter that I shall refer to later in my remarks upon drainage.

Q. (By Mr. KENNEDY.) Where does the water for irrigation come from—is it mountain drainage?—A. The water is from the mountain streams, fed in this case into Utah Lake, which is a fresh-water lake, and is taken out of the Jordan River.

Q. (By Mr. FARQUHAR.) What is the elevation between the Great Salt Lake and the river?—A. Twelve feet between the level of the river at Salt Lake City and the lake, but there is a ridge going through the district that gives about 2 feet per mile of fall on either side, and in addition to that there are extensive washes that extend up through the land that would form natural outlets to the drainage system. They run up for 8 or 10 miles into the country.

Q. (By Mr. KENNEDY.) Is the recession of the waters of the Great Salt Lake having any effect on the soils and climate of Utah?—A. It is having a great effect

upon the soils. The level of the Great Salt Lake has fallen 14 feet since 1865, and in our survey this year of the area around Ogden we mapped in 60,000 acres—about 10 square miles area—where the lake had receded, and we established the shore line of the lake in some places 9 miles beyond where the former survey had placed it.

Q. (By Mr. PHILLIPS.) What is the cause of the fall of that lake in your judgment?—A. There is an annual fluctuation that has never been explained, and there are periodical fluctuations that have never been explained. The level has been known to vary from period to period for reasons that are not at present known, but in addition to that the withdrawal of a large amount of water that is being used now for the irrigation of the surrounding lands, which does not go into the lake as formerly, is certainly a very large contributing cause to the lowering of the present surface.

Q. You spoke in regard to canals through the sandy soil portion, saying there ought to be something done to remedy the evil; have you any theory? Could the water be carried through pipes and thus prevent seeping through the soil?—A. I would state that in California, where water is more valuable, where the companies themselves are financially interested in how much water they sell, it is very common to protect canals from loss by seepage by running through wooden troughs or through wooden pipes, or as is frequently done where the water is carried through sandy areas, by cementing the sides and the bottoms of ditches. We have photographs (I wish I had brought them with me) of large-sized canals and laterals, constructed in California, with the sides and bottoms cemented.

Q. That would be entirely practicable to prevent seepage and thus prevent the destruction of lands below?—A. It is entirely practicable. In many cases simply the puddling of the canal would be sufficient, but where seepage causes injury by alkaline deposits, in my opinion, it should be stopped, and the companies should be required to protect their canals from undue loss.

Another cause of the abandonment of land is flooding and occasional inundations by storms and tides. The commission, of course, is well aware of the enormous losses from floods in the Mississippi Valley, and from the recent floods in Texas. This is a matter of such common knowledge that it hardly seems necessary for me to dwell upon it as one of the important causes of the abandonment of soils; where the conditions are so unsafe that settlers can no longer risk their lives or their crops. But I would call your attention also to the vast extent of the tide marshes and inland swamps of the United States. This question of the tide marshes has recently been brought to the attention of the Department of Agriculture from its economic importance in the New England States. It is estimated there are 168,000 acres of tide marshes along the Atlantic and the Gulf coast; and on the Pacific coast it is estimated that there are several million acres of tide marshes. These lands, if protected from the tide and drained, would be of value in agriculture. Some of the inland swamps of Illinois which were selling originally at \$1 to \$5 an acre have a value now of from \$60 to \$100 an acre. It is estimated that one-fifth of the area of Michigan is swamp land, which, if drained and reclaimed, would be of great value for celery and corn and potato crops. The tide marshes have also an indirect effect upon the values of adjacent lands, because of the prevalence of disease and the prevalence of mosquitoes. I would not say tide marshes only, but all marshes. The commission, of course, is aware of the commonly accepted views now that malaria is conveyed by mosquitoes, and the Department of Agriculture has been applied to recently from many sources to suggest means of reclaiming the tide marshes and the inland swamps of the United States, partly for their agricultural value and partly for the increase of the healthfulness of the surrounding land. There are many cases where areas and industries have been abandoned from the unhealthfulness of the neighboring marsh lands. I do not know that there is any cause that has contributed so much to the discomfort of many of the Atlantic coast States immediately upon the water, which would otherwise be a delightful location and a fine farming land, as the prevalence of malaria and similar diseases. That these causes have prevented to a large extent the settlement of some of our Southern States and have been the cause of abandonment of some others of our lands is unquestionably true. The prevalence of malaria and these malignant fevers near swamp lands of the South, the unhealthfulness which almost prevents the residence of white persons, is a matter that calls for very great and grave consideration, and it is one that the States, at least, it seems to me, might well consider.

An instance that I would cite as to the effect of inundation and floods as a cause of the abandonment of soils is in the rice lands of South Carolina. These lands before the war were protected by substantial levees that were built through cooperation between the individual and the State and maintained as a protection against the flooding of the fertile swamp lands by floods or by tides. During the

period of the civil war these levees were destroyed, the lands were for a time abandoned, and since that time it has been impossible to get labor to work in the canals, and it has been expensive to construct the levees, and large areas of this once fertile and extremely productive soil have been abandoned from this cause.

Q. (By Mr. CLARKE.) Why has it been impossible to get labor to reclaim this land—on account of unhealthfulness of the climate?—A. On account of unhealthfulness and the unwillingness of labor to work under conditions they have to in the swamp lands. In a way it would seem that machinery could be introduced, dredges; but so far as I know this has not been done on any extensive scale.

Q. Have you given attention to the development of rice growing in southwestern Louisiana?—A. Yes. The conditions there are that these lands, which were semiswamps, have been drained where necessary, and they are not subject to overflow, as the rice lands of South Carolina are. The Louisiana lands are higher, but still they are swamp lands, and the irrigation that is given to these lands is done by pumping or by artesian flow, usually by pumping, whereas the irrigation of the rice lands of South Carolina is from the rivers, and is without any pumping or artificial means, either for irrigation or for drainage.

Q. It is in evidence before the commission that the Louisiana rice region is very healthful?—A. That region is much more healthful than the South Carolina rice lands.

Another cause of the abandonment of lands, at least a contributing cause, is the expense of maintaining the proper physical conditions. The trouble and expense of clearing the stones off the New England fields have been so great and so laborious that they have had something, at least, to do with the abandonment of lands in that locality. The simple expense and labor involved in getting the fields into condition and maintaining them in condition to cultivate in competition with the large areas of the fertile western plains have been so great that they have unquestionably been a contributing cause to the abandonment of the soils. And the labor and expense and risk in maintaining the proper conditions of the rice lands of South Carolina, which I will refer to again, have been so great that there also these factors have operated against the continuance of the culture of the lands, and have been an insurmountable obstacle to the reclamation of what were once fertile and well-cultivated soils.

I would mention also the effect of transportation facilities. While cheap transportation has opened up new and important markets, it has also been the cause of the development of extensive areas of new and exceedingly fertile country. The effect upon this cause alone in the New England States and in the South has been very great, and will be referred to in a later place.

Another cause has been unquestionably the discrimination in rates and the high freight charges which have prevailed in certain localities. It is not my purpose to go fully into this question, as the commission have had in evidence before questions touching this important subject, but in my experience the commercial value of farm lands is often controlled to a considerable extent by the rates of freight which are locally applicable to these areas. It may be that the lands are situated at such a distance that cheap transportation can not be offered; it may be that there are conditions of expense in the marketing of the products, but certain it is that the possibilities of building up industries, agricultural industries, on certain soils and under certain climatic conditions which in themselves would be favorable is prevented by the impracticability of marketing the products with any profit under the prevailing conditions.

Q. (By Mr. PHILLIPS.) What section of the country is that most applicable to?—A. I would cite, in the case of Florida, the marketing of the bulky and tender products from the truck fields. These products have to be marketed under peculiar conditions. They have to be rushed to the Northern markets on the fast freight or passenger schedule. They have to be provided with proper refrigerating and ventilation cars, and they must be placed upon the market in the shortest possible time in order to be in fresh eatable condition, and to reach the market at the earliest possible date. Now, it is the common experience in Florida that the possibilities of marketing the crop with any profit to the farmer is a pretty close thing to figure on, and that it requires very nice and very close calculation in many cases to determine whether it is possible to send a crop to the Northern markets with any profit. I do not mean to say that there is discrimination, but I do want to show the commission that the possibilities of marketing the crop, the possibilities of transportation, have necessarily something and in many cases much to do with the possibilities of the development of any particular agricultural district, and that that is one of the important factors in the abandonment of many enterprises that have been started—in the abandonment of lands.

Another cause of this same kind which could be cited is in the marketing of the truck crops of southern Maryland. The development of the truck industry there a few years ago was very great, and the product had to be sent by river steamers to the railroad centers, or to the Northern market, and they were picked up by these steamers on their regular runs. The amount of product was large, the distance from the market was great, and the time that was consumed in getting the crop loaded and delivered in the Baltimore or Washington or Philadelphia markets became so great, and the transportation service was so irregular, that the industry on large areas has been given up for that one cause, namely, the inability to market the products in the proper way and in the quick time that is made necessary by our present transportation facilities.

Q. (By Mr. CLARKE.) You do not think that the difficulty of getting suitable farm labor for this truck farming was a potent factor in causing the abandonment of it?—A. Decidedly. I shall speak of the condition of labor in the South later on. This is an important contributing cause.

To come now to one of the most important problems—the social conditions and growth in manufactures, and the increase in wages. In treating this I shall take up specific cases, first, of the cause of the deterioration and abandonment of lands in New England, about which so much has lately been said. So far as I am aware, there is no evidence to show that the New England soils have any less plant food than they had when first cultivated. That is to say, that so far as the chemical analysis would show, they have all of the essential ingredients for crop production. I do not mean to say, however, that the soils are in as high a state of cultivation as they were, because I do not think that is universally the case; but the exhaustion of soils as it is usually considered has not contributed to any great extent to the present condition of the agricultural lands of New England in the 200 years in which they have been cultivated. It would be impossible, with the record we have of Eastern countries, to conceive that in 200 years these soils could be so impoverished by the actual withdrawal of plant food by the crops that have been marketed as to make them markedly deficient in plant food. We must remember that the country throughout the New England States has generally a rough, hilly, and frequently a stony soil, with rocks and boulders and gravel, left from the glacial period. The expense of clearing and cultivating these rough and rocky soils is considerable. With the development of the fertile lands in the West, with the ease of cultivation and the methods that can be employed, the cost of production has been reduced. The New England farmer can no longer afford to grow the staple farm products. When wheat was bringing \$1.25 and \$1.50 a bushel, as it was a few years ago, and when hay was correspondingly valuable and cattle a correspondingly important industry, the products from the New England farms were profitable. There is no question that the New England farmers made a comfortable living; but with wheat as low as it is at present, with cattle as cheaply raised as they are in the West, and with hay and grain as abundant, they have been unable to compete. The contributing cause of this condition has been the small areas which they could devote to any particular crop, and the labor and expense of cultivating and caring for their land. The development of transportation facilities, the lowering of freight rates in the rail and lake and canal transportation, has made it possible to bring products from the West at such a low price that it has been impossible on the rough and rocky New England soils to compete.

Another very important contributing cause has been in the increase in the number and size of factories. It is unquestionable that the social conditions of New England have changed in the past few years—that the growth of the factory system, that the increase in wages, that the lesser cost of the products of the mills, the increase in the number and variety of articles that are considered necessary for comfort and health, the general increase in the cost of living, the general feeling of discontent, and the unwillingness to remain in the quiet and laborious life of the farm have all had their influence.

It seems to me that of all the causes that have contributed to the abandonment of the lands in New England there is no other factor that has been more potent, more important, than this one, of the success of individuals in the commercial and industrial lines, and the apparent ease and comfort and luxury of their lives as compared with the laborious and simple life of the successful farmer.

Q. (By Mr. KENNEDY.) I read in the public press a short time since that the abandoned farms of New England were being taken up again at a very low price; that those who had abandoned them and gone to the West in many cases were returning and trying to get the old homesteads, and that if they could not do that they were buying abandoned farms in the neighborhood, and in one of the New England States, in Massachusetts or Connecticut, there was not now a single abandoned farm.—A. I think there is a reaction going on, but I should think that

statement rather overdrawn. Unquestionably, however, I think there will be a reaction, and that the lands will be taken up.

Q. (By Mr. PHILLIPS.) Have not a considerable portion of those lands been taken up by French Canadians in recent years?—A. Yes; they have. One other point I wish to convey to the commission is that lands in themselves are not worn out; they are in no worse condition. It is other conditions, and not the actual exhaustion of plant food, by which they are affected.

Q. (By Mr. CLARKE.) Is it not a fact that the products of agriculture in the manufacturing sections of New England are worth more to-day than they ever were before?—A. Do you mean of wheat and grain and fruit?

Q. I mean all crops grown by farmers, including, of course, truck farming.—A. Well, I should say not, so far as the general farming goes. Special industries are exceedingly important in the New England States, and I had aimed to speak of that fact in my suggestions for the amelioration of the conditions.

Q. Instead of manufacturing having the effect of depopulating the farms and of rendering agriculture unpopular, is it not true that manufacturing affords so good a market to the farmer near his farm that by changing his agriculture somewhat he finds it more profitable than ever before?—A. Have you not really given the key to the whole situation, namely, that they have not changed their method; they have persisted—farmers are a conservative class—in attempting to compete with the West, when they should have specialized and have met the changed conditions that have confronted them?

Q. My observation, as a New England man, reared upon a Vermont farm and an annual visitor to that State, and somewhat familiar with conditions in Massachusetts, where more manufacturing is carried on, is the reverse of that, and it is that they do conform to existing conditions and are making more money than they ever made before. Now, if I am wrong about that I hope that you or somebody else in the Department of Agriculture can enlighten the country on that subject. A few years ago a Professor Perry, of Williams College, made the statement that one-third of the farm lands from the summit of the Green Mountains in Vermont eastward to the Connecticut River had been abandoned. I contradicted it at the time from personal knowledge. That is one of the most favorable regions in this country. There is scarcely an abandoned farm to be found there, and agriculture near that region, while it has undergone some changes, is more profitable than ever before, and I would like to know why it is. As you say, the soils continue to be fertile and productive, and the markets have improved, and transportation facilities have improved; why is it, then, that the people will persist in claiming that there is a large abandonment of profitable agriculture in that region of the country? I undertake to say that it is not true, but that the exact reverse is true.

Q. (By Mr. PHILLIPS.) Is it or is it not the fact that the price of lands both in New England and the Central States, Pennsylvania, New York, and Ohio, are not nearly as valuable and would not bring as much per acre to-day as they would 25 or 30 years ago, or even before the war?—A. Generally, the land values have fallen, but in specific cases they have risen or have maintained their level. And in many cases in the New England States it is unquestionable that very important industries have been created there, notably the tobacco interests of the Connecticut Valley, which we have lately had under consideration, the area of which we have recently mapped; also the truck interests along the Sound, around Providence, around Boston, are very important, and the fruit interests of the lower Connecticut Valley, particularly the peaches, have all been exceedingly profitable, and I hope I did not convey the impression that I believed myself that there was any such general abandonment of lands as has been frequently stated in the press, because I think myself that there are many industries in the New England States now that are very important. It is certainly our most important tobacco section—the most important for wrapper tobacco—the finest we get in this country.

Q. Is it not a fact that throughout New England when a farm has been abandoned as a home it has been annexed to some neighboring farm and still carried on as a farm? Is not that almost universally the case?—A. I would not say universal, but it is generally the case; yes. There can be no question, however, that, particularly in the last 10 years, 12 years, there has been a period in New England in which agriculture has been at a low stage, and that there have been many abandoned tracts, and many people who have moved away. I have tried to show that these conditions are due to causes other than the poverty of the soil, which I do not believe in at all, and that there is no reason why they should not build up the industry of that country and make it as profitable as, and far more profitable by adjusting it to these new conditions, than it ever was.

Q. Now, I would like your estimate of the proportion, the relative importance of the causes which you have named which have contributed to this soil abandonment. Is it not, in your opinion, mainly due to the competition of the more fertile lands of the West—that is, the more easily tilled lands?—A. I should give that as the first cause, and I should give as the second cause, the increase in the factories, and the demoralizing effect of the factory life, and of the factory wages upon the farm people. There is a demoralization; it is more a panic than anything else; they have not the mature sense of perspective, the vision of what can be accomplished if they take new opportunities which have come to them. It is common through our Eastern States. It is a restless feeling that their old conditions have been changed, and a lack of that business planning and management that will enable them to fit their agriculture to new conditions.

Q. Do you think that the young men leave the farms in New England for the factories?—A. I think so.

Q. Have you any information on that subject?—A. I speak from my experience in New England. I lived in New England for many summers when I was a youth, and I have frequently visited there, as it is the home of my father. I spent 2 years at the Connecticut experiment station when these matters were under consideration, and have also done work since in the Connecticut Valley and in the truck areas of Boston and Providence.

Q. It may be true so far as the machine shops are concerned, and a few other skilled manufacturing industries. Is not the reverse true so far as the textile industries are concerned?—A. I should say that there is a general feeling among the farm boys in New England that they want the higher education. They want to get into and take up the professions. There is a great ambition on the part of the young men to go to an institute and to get into electrical works at the present time, because the young fellows that they may have been acquainted with are now getting high wages; and there is a desire among the young people of New England, so far as I have seen, to get into these commercial and industrial lines rather than remain on the farms, except where they are situated in communities in which special crops and special agricultural interests are being developed.

Q. Is it your opinion, then, that the system of education in New England is defective—that it tends to work against the best interests of agriculture?—A. That is a very difficult question to answer. It is a notable thing that few of the young men who go to the colleges for their so-called higher education attempt in any way to fit themselves for the farm, and a very striking case of that is found in the small number of students who have attended the agricultural courses at Yale University, which has had a permanent endowment for the purpose of agricultural education, and who have gone out from there as farmer boys. Harvard University maintains an agricultural school and a scientific or technical school, but there is by far a greater attendance at the technical school, as there is at the classical college, than there is at the agricultural courses. This is a question, of course, of the effect of education on farm life, which is widespread; it is found in all schools of the country. My own belief is that the education we are giving our boys is not calculated to make the best farmers, and that we are rather leading them away from the farm. I think there is a tendency the other way now, because we are showing that there are possibilities in agriculture that have never before been realized. We are showing them that there are possibilities of making money, for one thing—of earning salaries that are commensurate in every way with salaries paid to professional men. If we get a tobacco expert now we have to pay \$3,000 or \$4,000. Six thousand dollars is paid to some of the managers of tobacco estates in the South. The practical growers will willingly pay \$3,000 or \$4,000 to a man who can manage their estates and make them productive; and the same may be said in other lines of agriculture. In fruit and in dairy interests they think little now of paying \$4,000 to \$5,000 for experts in different lines—men who can make them successful. These possibilities now are opening up to young men, and they see opportunities for remunerative work. We have recently tried to get tobacco experts in the Department of Agriculture, and it has been necessary for us to pay \$4,000 to get a man who is qualified for the work. The Secretary has been desirous of having men trained, and I have presented the matter to several young men, and they have agreed to come at low salaries, \$40 a month—young men from colleges, and they are going to put themselves under the direction of this tobacco expert. They are going into the tobacco sheds and are going to learn how to handle the tobacco, and after they have acquired a practical knowledge they are going to have some training in our laboratories in the principles underlying the handling and manipulation of tobacco. The Secretary says, "Train young men for our own use." If we train them to make good tobacco experts they will go out from us at salaries of \$3,000, \$4,000, and \$5,000, just as we have lost men we have already trained. It is the training, it is the ability of these

men to produce products wanted now in this highly specialized industry of tobacco that counts.

The young men are seeing these opportunities, and we are able to get them now readily. They are readily coming to the Department because they acquire in our work an intimate knowledge of the operations on the farm, of the judging and classification of soils, of the treatment of alkali and seepage of waters and under-drainage, and of the production and management of tobacco, and we are having no difficulty in getting men who have been trained to some extent. Men are leaving positions in which they were getting \$1,000 or \$1,200 and coming to us for \$40 a month for the experience they will get and the value it will be to them. Some of our young men have had offers at \$2,500 or \$3,000 to go out and protect some of these Western lands from alkali, because they know how to handle the question. We have shown our ability to handle these questions, which are of so much importance to the people. There is one case which I wish to mention later of a sugar factory in California, that we found was situated on a delta plain. The owners have invested something like \$3,000,000 or \$4,000,000 in this plant, an immense sum, but their lands are underlain by alkali to such an extent that when they begin to irrigate, as they are planning to do now, there is no question in our minds that they will lose their crops and their lands also. Two factories have been shut up within the last 2 or 3 years from this same cause. They know that there is danger, and they offered one of our men a salary of \$3,000 just because he knew what the trouble was and could handle that matter for them.

A short while ago Japan took one of our tobacco experts from my own division and gave him \$6,000 to go over there to investigate the possibilities of raising and manipulating tobacco. They came again for another of our tobacco experts and offered him \$5,000 to go over and develop the interests on the island of Formosa. These things are having an effect on the people. They are seeing the possibilities in these special industries, and in my opinion the young men are turning more to the farm than they have ever done before, simply because there is something definite, there is a purpose, and they are willingly taking positions in the Department of Agriculture and the experiment stations, because they are getting into practical knowledge of these affairs. They are acquiring the practical methods and manipulations which give them control of these agricultural methods, and they are finding that they themselves can handle these industries now in a way in which they can make good money, or can get positions of trust and responsibility at salaries commensurate with what are being paid in commercial and industrial lines.

Q. (By Mr. CLARKE.) Are many of these branches of agricultural science capable of being taught in the public schools, say, of the grade of high schools and grammar schools?—A. I think so; and yet it is rather difficult to lay out a course or suggest lines of work and of teaching. But it seems to me, as you have asked me my opinion on this question of education, that we want more agricultural schools and we want, to say the least, no more agricultural colleges. That is, we want the schools right out on the farm lands where the boys work, where they are taught to care for products and for crops. When I want a tobacco expert I can not go to the agricultural colleges and get a young man who has any knowledge of tobacco. I must go to Florida or I must go to Pennsylvania, and I must pick up an otherwise uneducated man, and yet that man will command a salary of \$2,000, \$3,000, or \$4,000. He is not a college-bred man, but yet he is familiar with the manipulation and the details of that work. Now, if I should want to educate a young man in tobacco lines, to be a tobacco expert or to know how to raise tobacco in the Connecticut Valley, for example, I would take him and send him right to Florida, where they have the highest type of skill and industry in tobacco, so far as tobacco is concerned, of any place in this country. They have developed the industry along really scientific lines by their practical men.

Q. Now, most of the high schools of this country, even in the agricultural regions, have a curriculum chiefly devoted to preparation for entering classical colleges. Almost nothing is taught concerning practical farming in any line. Is it your opinion that the curriculum might be changed to the advantage of the farmer?—A. I think in certain cases it could be, and we would be extremely desirous of seeing in certain centers farming schools for the education of farming boys. If such a school were established in Lancaster County, Pa., under the splendid agricultural conditions prevailing there; if the boys could see the methods pursued there; if they could go out and actually learn how to handle stock, how to handle the soil, and how to handle the crops, they would acquire information in this individual locality that would be admirable in fitting them to take charge of estates and of farm lands of their own in other localities.

Q. Boys reared upon farms become familiar with practical methods; but what opportunity is offered to them in the neighboring schools to become familiar

with scientific agriculture? How much chemistry are they taught?—A. There is very little.

Q. What do they know about soiling crops and about the various plant foods and animal foods? Is any of that information taught in any of the high schools in this country that you know of?—A. Very little or none in any that I am familiar with, even in the agricultural districts.

Q. Then, when the system of education leaves the leading industry of a region to the work of ignorance and teaches the youth something else, are they not rather compelled to go out, and are not their ambitions led out into other pursuits?—A. Yes.

Q. (By Mr. PHILLIPS.) At present, it would be very difficult to have teachers qualified in these various rural districts to teach this. They would have to be educated for that purpose?—A. It seems to me, further, that when these schools are established they do not seem to be satisfied to remain schools; they so quickly aspire to the dignity of colleges, and from colleges to the dignity of universities. Abroad it is much more frequent to see real agricultural schools, a sort of primary school in agriculture, or high school in agriculture, where the school is situated in a farming district and the methods and thoughts are all upon farming lines. You take a young man and put him under those conditions and he is likely to be much more contented to follow in the pursuits of farming than if you put him into a university like Yale University where the farming course, the agricultural course, is looked down upon by all other students. Under such conditions the young men are not generally satisfied to take a course which is popularly supposed to be an easy one and one which does not maintain the rigorous training that the classical and mathematical lines are supposed to possess.

Q. Perhaps we have diverted you most too long. This is very interesting.—A. I wish I had prepared myself a little more on this line. I did not think of this coming into the discussion. It is a matter that I have often thought of, because I was professor of agriculture in South Carolina and always realized that I was not doing my duty, as it seemed to me, in the training of my men, partly because there is no course in agriculture for a professor to take up—he has to make one himself—and, secondly, the opportunities are not presented, it seems to me, to train people with the particular knowledge that is required in any line of agriculture. I think that in the New England States, perhaps even more than in the Southern States, that restless desire for material advancement and the higher education has been felt because of the more thickly settled condition and other natural conditions which have already been referred to. Another contributing cause to the tendency in the New England States has been the demoralizing effect of the summer boarders. It seems to me there is no question that, while their presence has been a benefit to the New England States in the main, it has had a demoralizing effect upon the agriculture of the region. Furthermore, the severe climate of New England has been against the development in some cases, and it has had some effect upon the development of the agricultural resources of the area.

It seems to me perfectly evident that the conditions which have contributed in any marked way to the depreciation of land values in New England have been, first, the development of the West and the lower prices for farm products through the development of the transportation systems, and the increase in the number of factories, in the restless desire of all of our people to a certain extent to leave the quiet and laborious life of the farm and enter the busy, hurried world of commercial and industrial activities. It is quite evident to me, however, that the future for the New England States, as for our Southern States, is in the line of specialization. They are close to the markets; they are peculiarly fitted, as they have already shown, for certain special industries; and the line of future development must be in that direction. They must give up all thought of competition with the general farm crops and must look forward to the building up of certain industries which their position, their locality, and their conditions specifically make possible to be carried on.

The one case of the Sumatra tobacco, that we succeeded in growing last year in the Connecticut Valley, that brought 71 cents a pound when the ordinary crop is grown for 20 cents a pound, was a result of soil-survey work, in which we thought that the conditions were favorable on a certain soil in the Connecticut Valley for the production of this tobacco under certain conditions which we brought about, and the result has been successful. So far as we know, there is no other area besides Florida and the Connecticut Valley, and only certain soils in the Connecticut Valley, where this industry can be pursued; and it is unquestionable in my mind that this industry can be built up, and that there is a possibility of producing \$6,000,000 worth of tobacco which we now import from the island of Sumatra every year.

I should also mention that the truck interests and the greenhouse interests around Boston are very great. They are enormous industries, and large amounts of money are invested in them and large profits maintained.

I come now to the cause of the deterioration and abandonment of lands in Maryland and Virginia.

The exhaustion of the soils, of which we have heard so much in Maryland, Virginia, and the Southern States, is due, unquestionably, to improper and injudicious methods of cultivation and cropping. This will be referred to more at length, under the head of fertilizers, when we come to speak of remedial measures. It is also due to the decrease in value of farm crops, due in turn to the cheaper production in the West and to the reduced cost of transportation, as has been referred to in the case of the New England States; also to the increase and the development of special industries in other localities—for example, in the production of the White Burley tobacco in Ohio, which yields more per acre, is grown at a less cost per pound, and can be sold at a cheaper price than the Maryland leaf, and has largely taken the place of the Maryland leaf in the foreign markets, particularly in the French and Belgian markets. Furthermore, the changes in the social conditions due to the civil war, and the mortgages which are still outstanding against the lands have been a contributing cause to the abandonment or to the deterioration of many of these areas. It has been found possible in many portions of Maryland, with the prevailing crops and methods of cultivation, to obtain a fair interest on the labor and expense of cultivation, but it has been impossible to obtain a living from the land if at the same time the interest on mortgages, which have been running since the war, has had to be met. And I know of once prosperous communities in southern Maryland where they could still be successful, where they could produce sufficient to maintain families without stint and with a fair degree of comfort, but where nearly all the farms are mortgaged as an inheritance of 30 years ago, and it is impossible to support the families and to pay off the mortgages at the same time. Areas now are being abandoned from that cause throughout Maryland and the South.

One of the most important causes of deterioration, however, and I think I should put this first of all, is the method and system of agriculture that prevails throughout these States. The Division of Soils made a careful soil survey with soil maps of two of the counties of southern Maryland this year—St. Mary County and Calvert County—and of Lancaster County, Pa.; and the study of the conditions which have prevailed and the methods, particularly, which have been used in these two areas has been a matter of considerable interest to me. In the first place, I would state that the soils of southern Maryland are in no way exhausted in the sense that that term is generally used—that is, a chemical analysis shows that they have sufficient plant food for innumerable crops and that there is apparently no lack of plant food in the soil. Unquestionably, the soil has been abused, the methods of cultivation and of cropping have been injudiciously selected, and the soils are not now as productive as they should be. There is one area in particular of a certain soil with a heavy subsoil in St. Mary County, probably about 40 per cent of the area of the county, that is, in my opinion, as valuable in its way, and in much the same way, as the limestone soil of Pennsylvania. This soil in St. Mary County sells for from \$1 to \$3 per acre in forest, as it usually is, or for about \$10 an acre where it is under cultivation, while the soils in Lancaster County sell now at from \$125 to \$250 an acre.

Q. (By Mr. PHILLIPS.) That is chiefly for tobacco, is it?—A. Yes; chiefly for tobacco. It is fit for general crops, but tobacco is grown in places. But on the soil in St. Mary County there have been several good farms that have been well kept up. The Maryland farmer grows on soils in good condition from 15 to 20 bushels of wheat; he grows clover; he grows tobacco, and he gets from 6 to 10 cents a pound for the tobacco. The Pennsylvania farmer grows from 25 to 35 bushels of wheat; he grows clover and grass, as in Maryland, under good treatment; and he grows tobacco, for which he gets from 6 to 10 cents a pound also. He gets the same price, but a larger yield. It is heavier tobacco. Now, from consideration of the crops that are obtained from this southern Maryland area, and of the staple crops and of the yields and values obtained from the soils of Lancaster County, Pa., it seems to me evident that the soils of southern Maryland ought to have a relatively higher value; and the reason why they have not is largely, in my opinion, because of the social conditions and the methods of farming. If you go into the home of a Lancaster County farmer and sit down to dinner with him, he has an abundance of food in great variety. Everything, the chances are, has been grown upon his own farm. The meat has been raised by himself, the vegetables have been grown in his garden or in his fields, the preserves, or whatever they may have for their dessert, have been made by their families from the products of their garden. Even the sugar, the chances are, has been pro-

duced on the place, and actually nothing but the tea, coffee, salt, and pepper have been purchased that goes to make up the family meal. The families as a rule are large. They have a good many children. The boys and girls are all brought up to work on the farm. It is the rarest thing that any of them leave the community or leave the farm. They stay there and they marry. It is a common thing for them to settle on a portion of the farm or on some neighboring farm. The farms are small, and labor is all done by the owner and his family. The girls are all brought up to look after the house. There is no expense for servants. They have their garden and their fruit. They put up their preserves and their apple butter, and such things for their winter use. We find that very few products are sold from Lancaster County; very few things are sent out of the county except tobacco and stock. And they not only feed up all their corn and hay that they grow to the stock, but they import it often from other States and from other countries, so that they can raise more stock and make more beef and mutton. Most of the products of the farm, including the wheat, which is ground up for flour in adjoining mills, are used on the farm or manufactured there into some sort of product that is sold or is used up in the district. There are manufactures and industries which require to be kept up in the large city of Lancaster and many smaller towns, in which there is a ready market for everything that is produced in the county; and the interesting thing is that this supply and demand is nearly equal, so that very little is sent out of the county and very little is brought in. The result is that it is a happy and contented and prosperous community. The lands have been handed down from generation to generation for ages and people seldom think of leaving the place. They are a contented and happy and prosperous people.

In Maryland the methods are altogether different. In the first place, the Maryland farm is seldom worked by the man who owns it. There is, for some reason, an unfortunate prejudice which prevails in many localities, at any rate in Maryland, for a man who actually goes into the field and works his land. He usually has an overseer, a man who is paid to look after and direct his interests instead of doing this himself. Frequently he has not even so much control over his interests, and lets his land out to a tenant farmer who farms it in his own way, by his own methods, and for a portion of the crop, and occasionally for a money consideration. The crops grown are the ordinary staple crops of general agriculture. They have corn, wheat, and tobacco. The competition from the West and the low prices of wheat and corn make them scarcely profitable. The competition with the Ohio tobacco and the general specialization which has taken place in the tobacco industry, and the necessity of producing something that is peculiarly adapted to a certain market or to a certain demand, has lowered the price of the Maryland tobacco. Now, after the Maryland farmer has raised these three things he has done, as he thinks, the best he can, and he has nothing further to consider for his development. The corn is fed mainly to his work stock, and it all goes to that and his own labor. The wheat is sold and sent off the farm in exchange for flour, which he buys at a considerable increase in cost over what it would have cost him if he could have had it ground in his own neighborhood. The tobacco, of course, is sold and goes out in exchange for productions of all kinds for himself and his family. He buys his meat, he buys his groceries, and he frequently buys the vegetables that he should have raised in his garden.

There is no comparison with the conditions in a prosperous community like Lancaster County and the improvident methods that prevail in some of our Maryland counties and Virginia communities. There is no comparison whatever in the economical methods that are employed; and it seems to me that one of the most important contributing causes to the abandonment and impoverishment of the lands in Maryland and Virginia and of many of the Southern States is due to this one fact, that they do not use the same thrifty methods that have marked the success in Lancaster County and in many other of the Northern States.

Mr. PHILLIPS. Without objection a recess will be taken until 2.30, when the professor will be with us again.

Whereupon, at 1.05 p. m., the commission took a recess until 2.30 p. m.

WASHINGTON, D. C., March 12, 1901.

The commission met at 2.30 p. m., pursuant to recess, Vice-Chairman Phillips presiding.

Prof. MILTON WHITNEY was still on the stand, and examination was resumed as follows:

Mr. PHILLIPS. You may proceed.

The WITNESS. At the time of the adjournment or recess I had compared the methods and system of agriculture prevailing in the southern counties of Mary-

land with the system prevailing in Lancaster County, Pa., and had drawn some suggestions as to the cause of the differences in the land values in the two localities. In following out our soil investigation and the mapping of lands, we find the same limestone soil which is so productive and valuable in Pennsylvania extending down to the Hagerstown Valley of Maryland and down through the Shenandoah Valley of Virginia. They have the same character of soil, essentially the same climatic conditions, and yet the soils of the valley of Virginia are selling to-day at from \$10 to \$20 an acre—rarely more than \$40 or \$50 an acre—while the farm prices in Lancaster County have been maintained about where they were—about as high as they ever have been—and I can not say that this is due to any cause connected with the soil, but conclude that it is due almost entirely to social conditions, to the respect agriculture has in the community, to the thrifty methods employed by the people, and the way in which the occupation is esteemed.

Undoubtedly, the system that has prevailed for so many years in the South was satisfactory under the conditions prevailing some years ago, but certainly, with the rapid and phenomenal advance and improvement in industrial lines and in the improvement of transportation facilities, the old methods are no longer applicable. The trouble with the South, it seems to me, is the lack of business method, the lack of appreciation of the changed conditions, and the necessity for business perception of opportunities that could be taken up and made productive.

In the States farther south than Maryland and Virginia there have been other causes which have operated in this same direction. In the first place, the kind of crop and the clean cultivation that has been given to the cotton crop has caused a tremendous oxidation and loss of the organic matter, and the soil is left relatively poor in these organic substances that are necessary for the normal weathering of the soil material and the preparation of the plant food into a form that is readily available to plants. It has also caused in many areas the erosion and washing of lands that has proved destructive to very considerable areas in the Southern States. There is one condition which has also prevailed against the competition with the South in certain lines of general agriculture—that is, the unfavorable climatic conditions for grain crops. The normal yield of grain in the South is about one-third of what it is in the Northern States. This is due to the fact, so far as we can see, that the greater humidity and larger rainfall are bringing about conditions favoring extensive leaf development rather than the production of grain. In the Northern States the cold, frosty nights are liable to occur about the time the plant has obtained its full development, and this condition favors the production of fruit, as is well known in all life functions. Where there is danger of the destruction of the plant it tends to reproduce itself in the formation of seed. In the Southern States, with the more equable climate, with the higher temperature, higher rainfall, and generally higher humidity, there is a persistent effort to the production of vegetable growth and a distinctly less chance of the production of grain and seeds. While this is natural, it is by no means necessary, for the largest yield of corn on record is from South Carolina, where there was an abundant growth—abundant vegetative growth—which was checked by methods of cultivation at the proper time—that is, the tendency to vegetative growth being checked, the plant produced seed in proportion to the vegetative growth, and the yield was phenomenal; and it has seemed to me at times as though by a change in the method of cultivation—by some mechanical checking of the growth—that the vegetative growth could be checked and the yield could be largely increased. However that may be, the fact remains that the climatic conditions in the South have never been favorable to a large yield of grain.

I have presented to the commission now the principal causes that operate in the exhaustion and abandonment of soils. These several lines, of course, operate in different proportions in different parts of the country. In nearly all localities one or more of the causes that I have mentioned have operated at the same time to produce the deterioration, if not the abandonment of soils.

I come now to the conditions of reclamation and certain recommendations that it seems desirable to make.

Q. (By Mr. PHILLIPS.) Before proceeding with that I should like to bring up a question which has been touched upon. You said in the early part of your testimony that in England the soils had not deteriorated; that the growers raised about the same amount on the land in the last 20 years as they had for 40 or 50 years, about 15 bushels. Is there anything in the climate favoring England in this respect? Would the climate in Virginia and Pennsylvania have the same power or force? Is it on account of the damp, or are the climatic conditions there different from ours?—A. Yes; the climatic conditions have a great deal to do with it.

Q. Then you would not, therefore, claim that 15 bushels could be raised on good wheat land in Pennsylvania, as is the case in England?—A. No; but what I

say is that under given climatic conditions and with a given soil, a soil even without fertilizer, there would be a certain grain yield that would be maintained for a good many years; indefinitely, so far as we know. It might be 5 bushels to the acre or it might be 10, or it might be 15. It happens to be that under the conditions in England in this one experiment, it was 12 bushels.

Q. I know of farms that have become quite poor on the hills because of the water. England being more level, perhaps the conditions would be more favorable?—A. In this experiment that I cite, yes; it was conducted on a level tract.

Q. Pardon the interruption and proceed.—A. The first method that I will speak of in the reclamation of lands, although in my opinion not the most important, is the subject of fertilization. The primary object of fertilization is the improvement or adaptation of soils to the cultivation of any desired crop or crops. As I have shown, all soils have a natural fertility which can probably be maintained under any condition of cultivation for an indefinite number of years. Very frequently this natural fertility is so low that it is unprofitable to raise a particular crop, as so little is obtained from the soil that it does not pay for the attention given to it. Frequently, also, on a very rich soil the aim is to force the crop, and we call it intensive cultivation—that is, we may have a soil which will produce a large crop, and yet we want to force it to produce all it can. It is like the fattening of stock. We can produce a fairly good animal on our ranges, but if we take an animal and feed it up with concentrated food mixed in the proper proportions for a good diet we can put fat and flesh on it, which will make it far more profitable than if we had depended upon the natural food of the locality. It is so with soils. We can unquestionably force the fertility far beyond the natural limit and far beyond the ordinary limits of crop production. This we see particularly in the truck crops, where the poor barren sands are highly fertilized and where large crops are grown from what would naturally be considered a poor soil. In this sense the effect of fertilization is a simple addition of plant food to the soil in such form that the crops can immediately use it. But fertilizers have another effect, that of increasing the decomposition of the soil particles themselves—that is, the mere addition of fertilizers of different kinds may increase the weathering power, and the soil itself will disintegrate and decompose under their influence faster than it would without their application.

The specific objects of fertilizing are to obtain an improvement in the texture of the soil—that is, frequently a wet refractory clay can be made more pliable, more easily handled; drainage is improved. Frequently also loose soil may be made more compact and more retentive of moisture. At times also the influence of the fertilizers is felt more in balancing up the ratio. We have in Maryland and Pennsylvania small areas of lands that are derived from the disintegration of serpentine rocks that carry a large proportion of magnesia; and it has been found that where the amount of magnesia is in excess of the amount of lime plants rarely do well and frequently are an entire failure. In such case the application of lime simply to reverse the ratio and make lime a predominating ingredient in the soil will restore the fertility of the land. Very frequently also, and probably more often even than we now suppose, soil is acid. It has been found that the soils of Rhode Island are very generally acid, and the addition of lime simply to neutralize this acidity will promote the fertility of the land in a very remarkable degree. This same cause of acidity of the soil is found now to be much more prevalent than we have heretofore supposed to be the case. The fertilizers that are commonly available are farm products—that is, stable manures and green manures, which are used to a very considerable extent and are both exceedingly important in the list of fertilizing materials. Then we have the commercial products, such as guano, ground bone, potash, and then the mineral fertilizers other than lime, and then lime, marls, and gypsum. It will hardly be necessary for me to go into the question of the fertilizer laws. As the commission knows, most of the Eastern States have rather stringent laws about the inspection and sale of fertilizers; and this subject has been taken up by the Department of Agriculture with the idea of having a more uniform system of laws, if possible, and with some idea of having national laws for the interstate commerce and trade. I am not at all sure how far this has gone, and I therefore do not feel competent to speak upon it.

Another series of fertilizing agents is found in the bacteria and other ferments. This newly discovered nitrogen, is really a pure culture of bacteria, which have by reason of their activities in the soil rendered available the plant food—that is, they increase the weathering of the rocks and also add to some extent (we do not know how much) nitrogen from the air, converting it into some form in which it can be used by the plants.

Still another method which I would call to your attention by which reclamation of these waste lands can be realized is in the rotation of crops. There is no question

whatever but that in general a rotation or a change in the crops grown on soils is of value in preventing undue waste and undue extraction of certain elements of plant food and the undue tendency for cultivation in a particular way, and unquestionably where intelligent rotation of crops can be inaugurated it is one of the most desirable things to do. There are instances, however, in which the same crop has been grown on the same land for many years without any apparent deleterious effect. On the eastern side of the Connecticut River, near Hartford, they have grown the broad leaf tobacco continuously for 25 years on the same land, and they claim that the quality of the tobacco as well as the yield is as fine as it was at the beginning, even better.

Q. Is that done without fertilizing?—A. No; that is with fertilizing.

Q. (By Mr. FARQUHAR.) Why is it that the tobacco soils of Virginia here are almost worthless to-day for raising anything?—A. The deterioration of the tobacco lands of Virginia is due more to the general methods of cultivation which have not looked forward to the maintenance of the fertility of the land or to the proper physical conditions. You will find it almost universally believed in Maryland and Virginia, that tobacco is a very exhausting crop and has ruined their soils. On the contrary, if you go to Ohio, or Kentucky, or Pennsylvania, or Connecticut, you will find that it is the one crop which they value as a renovator for their soil. This is, in my opinion, due to the fact that they take so much care of their tobacco lands. They cultivate them so carefully, so perfectly, and so thoroughly; they fertilize them so heavily in order to maintain a good yield and a good quality, that the land has actually improved in spite of the relatively large amount of plant food removed by the crop. I think unquestionably it is a matter of culture rather than of any other one factor. If the Virginia farmers took as good care of their land as they do in other localities, there would be no suggestion of deterioration of their soils. But they plant tobacco with little or no fertilizer, or manure, usually without much organic matter. They give the land a clean cultivation and leave it exposed for a considerable portion of the year; and the consequence is that it is not maintained in that vigorous condition in which these necessary changes go on as they should, and the soil is said to be worn out. It is not the loss of plant food; it is a change in the physical and chemical condition of the soil brought about by indifferent methods of cultivation.

One of the most important methods for the reclamation of abandoned and exhausted lands is in the specialization of crops. By this I do not mean the exclusive growing of one crop without regard to all other conditions, but I do mean the adaptation of the particular crop or crops that the land is best suited to, and specialization in that particular industry. I shall cite in support of this position the truck industry which has reclaimed vast areas of lands in the Atlantic States. Twenty-five or 30 years ago the sandy soils along the Atlantic coast were worth about \$1 or \$1.50 an acre. I remember myself well when they were worth no more than this. By the introduction of the truck crops—that is, the growing of vegetables for our early markets—those lands have risen in value until now they are the most valuable soils in those States, selling anywhere from \$50 to \$500 an acre according to their location with regard to the water, freedom from frost, and in regard to the markets and transportation facilities.

Q. (By Mr. PHILLIPS.) You do not mean in the primitive state, but that under a state of cultivation they are worth that amount?—A. Yes; I mean that the same land that was worth \$1 an acre is now worth \$100.

Q. By reason of cultivation, and not in the natural state?—A. In the natural state. Any soil that is suitably located for truck farming, especially near the water, and where there is a freedom from frost, and where the transportation facilities are adequate, is worth that in its natural state.

I should also state a similar fact as to the case of the pineapple industry in Florida. There is a narrow strip of sand along the coast in the southern part of the peninsula of Florida that was formerly comparatively worthless. It is simply beach sand thrown up by the tide in former times, and is in a ridge about 15 or 20 feet high. It is white, like glass sand, and to the northern farmer would be just as barren and unpromising as anything could be. By the introduction of pineapples these lands have been redeemed, and a very fine variety of pineapple can be grown upon them. They are worth now anywhere from \$200 to \$1,000 an acre, according as to whether they are set in pineapples or whether they are wild lands. Even the wild lands, covered with the native jungle, will sell now for from \$100 to \$200 an acre, when favorably located. I know of no more striking illustration of the possibility of specialization in the reclamation of waste and abandoned lands than this instance of the pineapple industry of Florida.

Q. Are they fertilized?—A. Fertilized very heavily. The sand is used simply as a medium apparently for the fertilizers that are put on. They would be of no value for general crop, but are of exceptional value for this one crop, because there

is no other soil which can compare with them in the possibilities of growing pine-apples of the superior quality that is grown on them.

Q. That strip is in the southern portion of the State, is it not; below Palm Beach?—A. Just above Palm Beach. It begins about there. It extends from Jensen down to Palm Beach.

I would also cite the case of the bright tobacco industry in the South. Many areas that were formerly of little value and considered very unproductive, have been developed by the introduction of that industry, and are now worth more than they were formerly, and are the most productive and valuable lands in that section. In this case, also, it is a special adaptation of a particular kind of crop to a particular soil. The bright tobacco can not be grown successfully on all soils. It is confined to certain soils with certain peculiarities, and they happen frequently to be conditions which are unfavorable for the general agricultural crops, fortunately.

I would cite another instance of the cultivation of tobacco in the Connecticut Valley. On the light sandy soils a fine grade of wrapper leaf is produced which can not be grown on the tobacco lands of Pennsylvania or of Maryland. It is confined to that one locality of the Connecticut Valley and the Housatonic Valley, and is a special industry that seems to be adapted to that place. The introduction in 1865 of the Sumatra tobacco from the island of Sumatra has had an effect upon the tobacco industry of the Connecticut Valley. The fine texture and fine veins and the working qualities of this Sumatra tobacco have been so appreciated by the cigar manufacturers that it has been imported in increasing amounts ever since, in spite of the revenue duty of \$1.85 per pound on all that is brought into this country. In other words, the cigar manufacturers prefer paying \$2.50 or \$3 a pound for Sumatra tobacco to paying 18 cents, or 20 cents for the Connecticut leaf, although, as far as quality goes, the Connecticut leaf is preferred by many. Now it has seemed to me that the industry in the Connecticut Valley was threatened. The trade wants this Sumatra type of tobacco, and have been giving but a low price for the Connecticut leaf. One dollar a pound is paid for the Sumatra and \$1.85 a pound is paid as duty upon it. We only take the best that they have, and there is more and more a feeling against the use of the domestic leaf.

Realizing this condition and the necessity of successfully competing with the Sumatra tobacco, the Department of Agriculture 2 or 3 years ago looked around for the possibility of raising a Sumatra tobacco in this country which would prevent the importation of such large quantities from that island, and we decided to try a particular soil in the Connecticut Valley.

Last year we procured some Sumatra seed and planted it under a shed. This shed was erected at the height of about 9 feet, and was covered with cheese cloth so as to partially protect the plants from the sun and maintain a very quiet and humid air. The tobacco was grown and cured by the methods used in Florida and in Sumatra and Cuba—a combination of the different methods—and it was pronounced by experts in New York and Philadelphia to be fully equal to the Sumatra leaf that is imported. We confidently expect to be able to establish an industry in the Connecticut Valley upon certain soils adapted to this very fine leaf, in which we hope to be able to successfully compete with the Sumatra tobacco, which we import to the extent of \$6,000,000 a year in addition to the duties.

Q. Could it be profitably produced by covering the ground with canvas as you describe?—A. Yes; the profits are good.

Q. Could it be produced without the covering?—A. No. That is necessary, in order to change the climatic conditions to get the particular growth that we want. Even with the expense of \$500 an acre, which we estimate for the first cost, the profits are likely to be large. We estimate this year \$1,400 worth of tobacco from our experimental crop of one-third of an acre.

Q. Have you sought any lands in the South where the climatic conditions would be somewhat similar to those of Sumatra, without the canvas?—A. Yes. Some Sumatra leaf is being grown in Florida and the growers are getting large yields. Their finest wrappers are bringing from \$2 to \$4 a pound.

Q. They raise it, then, without canvas?—A. No; with canvas there also. The climatic conditions during the growing season are not very different in Connecticut and in Florida. It is the same hot, tropical weather.

Q. (By Mr. CLARKE.) Is that cheese cloth strong enough to protect the leaves from hail?—A. There is no ill effect from hail, except possibly an exceptional storm. There is no injury from wind or from insects or worms of any kind. The protection is carried all the way down the sides. There is a gate with an opening for men and teams. It is entirely covered with canvas, and it is a perfect protection against all extraneous conditions.

Q. (By Mr. PHILLIPS.) It would be liable to destruction by storm, would it not?—A. In a very severe storm such as they had two or three years ago in Florida, where one of those gulf towns was destroyed by the floods that came up, they were destroyed to a considerable extent; but ours in the Connecticut Valley last year withstood the most severe storms. Any ordinary storm has no effect on it.

Q. (By Mr. CLARKE.) Can you give the expense of constructing and maintaining these canvas coverings?—A. The first cost is between \$200 and \$500 an acre. That seems rather a wide margin, but it depends on the cost of the lumber. In the South, where they have the sawmills right on the place and where lumber is cheap, it costs about \$200 an acre for the shed. In the North it will not exceed \$500 an acre, and the shed will last about 5 years. The cheesecloth will cost about \$100 an acre, and has to be renewed each year.

Q. (By Mr. PHILLIPS.) Is it taken down in the winter season?—A. The cheese cloth is hardly worth preserving.

Q. (By Mr. CLARKE.) Are those coverings for each row or are they broad enough to cover several rows?—A. The covering goes entirely over the field. It is 9 feet high, so that horse cultivation is carried on under the shed just as it would be in the open air. It may be a 10-acre field, or it may be a 30-acre field, but the entire field is covered.

Q. Like a great greenhouse, then?—A. It has the effect of a great greenhouse. The sunlight and the sun heat is very much reduced and modified, and the air is a stagnant and moist air, humid, because there is no wind to carry off the moisture or change the air. The conditions there are really tropical. The plants keep on growing, and in the Connecticut Valley they went right up to the top of the roof; that is, they were 9 feet high.

Q. (By Mr. KENNEDY.) What is the ordinary height of tobacco plants?—A. Ordinarily, about 4 feet.

Q. (By Mr. PHILLIPS.) This cheese cloth does not prevent the rain going through?—A. No. It does not prevent the rain, but it does prevent evaporation, and it conserves the moisture so that the crops do not suffer as much from drought as they do on the outside. It is also a protection against frost. Indeed, a covering of the kind described has been used very successfully in the cultivation of pineapples in Florida to protect them against frost. It seems to be a method that is coming into very extensive use in the protection of crops under intensive farming. In the production of truck crops, it is getting to be used extensively to protect them from frost and to maintain humid conditions and protect from drought on the sandy soils.

Q. In a very large per cent of these the flavor is due to the direct rays of the sun. For instance, strawberries would not be marketable raised under such conditions?—A. No; I should not think strawberries would. There is some sunlight under the cloth covering, but it is not so intense. It is the intense sun in the middle of the day that hurts some of our tender vegetables unless they have plenty of moisture. Covered, they have the sunlight, but it is diffused and not so intense as it is outside.

The commission is well aware of the important part celery has played in the reclamation of many areas of formerly wet, mucky lands in many parts of the country; also the importance of the fruit industry in the reclamation of what we considered worthless or abandoned lands.

The introduction of peach culture in Western Maryland has created an industry there on some of the soils which were formerly of little or no value, and where they are now worth anywhere up to \$1,000 an acre. The location and the character of the soil has made it possible to produce a late peach which does not come into competition with the peaches from the Eastern Shore and Southern Maryland, and which has a very fine color and a splendid flavor. These soils are of no value for general farm purposes, but they are particularly adapted to the production of peaches which ripen late, and which have a good flavor and a bright color.

The commission is also aware of the success of grapes and vineyard culture on gravelly soils, and it will hardly be necessary to dilate on the importance of this crop as a means of reclaiming such areas. The most valued soils along the Rhine are frequently so destitute of soil covering that the soil has to be maintained by stonework; and on these very gravelly soils the finest varieties of grapes have been produced. Over a large class of soils, particularly in rocky and stony areas, fruit trees and grapevines have been found a most important means of reclaiming otherwise worthless lands.

There is one consideration, of course, in the production of fruit which must always be considered, and that is the possibility of marketing. That problem has been solved to a considerable extent by the possibilities of marketing the fruit in a dried or canned condition, and the exportation of dried fruit is to-day a matter of the greatest importance, and one that is increasing in magnitude, especially on

the Pacific coast, where large and increasing quantities of fruit are being consigned to China and Japan.

Another important means for the reclamation of poor or abandoned lands is in the reforestation and the protection from fires and a more rational method of cutting the timber. This is a subject which is being investigated in the Department of Agriculture, where we have our Division of Forestry concerning itself with this one problem; and it is one of the important problems applicable to areas in which there seems at present to be no other means of improving the land.

The question of thrifty methods and efficiency of labor is one that is very hard to deal with. I can not understand how by education or by legislation or in any other way thrifty methods can be introduced into certain areas that are at present of little value simply because the methods are not good. I do not think that any kind of education would improve the farming conditions in southern Maryland and make them particularly attractive to the young man. It would be discouraging, no matter what kind of education he had, for him to go back and live under the conditions that prevail there at the present time. The social conditions are such that he can not work with his own hands, and he does not have the intelligent or efficient labor to organize and carry out his ideas. He is confronted from the start with conditions that are almost hopeless for the introduction of new methods and of new crops on a scale commensurate with the importance of the work and the facilities at his command.

Q. Is the negro population very numerous in southern Maryland?—A. It is quite large. It is the principal but not the only labor, and not nearly so large as it is farther south. In my opinion, the importance of reclaiming large areas of lands is indicated by the necessity of more thrifty methods and more businesslike plans than they have at the present time in the selection of industries and in the cultivation of crops.

Another very necessary means to the reclamation of lands is business methods and organization in the marketing of crops. The success of the truck industry in Norfolk is largely due to the splendid organization and to the means by which the truck farmers place their crops in certain markets, according as the demand may be greater in one or the other. That is an essential thing in truck farming, because the vegetables can not be held over, but must be marketed or sold as soon as they reach maturity, and they have to be sold for what they will bring. The organization of growers gets regular daily returns of the market conditions in different cities, and they are able to divide their crops and to send a certain portion to this market or to that, according as they think the conditions will stand. It seems to me that this organization and the introduction of these business methods is one of the most important factors in the reclamation of abandoned areas and the introduction of new crops.

The commission is, of course, quite well aware of the method of irrigation which has been so important in the reclamation of certain areas in the West. Unfortunately, about all of the available water has been already appropriated and is nearly all in use.

Q. (By Mr. KENNEDY.) Is that true? Governor Stenness, of Idaho, told me a week ago last Sunday that the possibilities of the Snake River for irrigation purposes were wonderful, saying they had not begun to use the water of the stream up to its full capacity.—A. That is so in certain cases. It is so in the case of the Yellowstone River, also. But nearly all of the water in California and in Washington and in certain portions of Arizona and in the Pecos Valley in New Mexico is now used to its fullest extent. There are other areas in Montana and in Idaho and in Wyoming where there is still some available water, but as a general statement it may be said that the available waters are already appropriated and in use, except, as I was going to say, such as may be added by the construction of reservoirs for the storage of waste waters.

Q. (By Mr. PHILLIPS.) There are very large possibilities in that regard, are there not?—A. Yes; it is estimated that about 74,000,000 acres can be irrigated by the construction of reservoirs.

Q. (By Representative BELL.) What are the possibilities of the irrigated soil?—A. They are very great for special crops, but they are not so very great for our general crops. For instance, it no longer pays to irrigate wheat. The principal crops are the fruit crops of all kinds, and alfalfa for stock feeding, and special industries of that kind. With these special industries the possibilities are enormous.

The average cost of placing land under irrigation, as shown by the last census, was \$12.12 per acre, and the annual cost thereafter of maintaining the water was \$1.07 per acre of the public lands. Newell estimates that 74,000,000 acres are capable of being irrigated. The cost of the opening of this area, taking the average of previous experiments, would be \$897,000,000. But as the methods of apply-

ing the water to the land heretofore have been the simplest possible, the cost per acre has been much less than the cost will be in the new areas that are to be taken up, where the water must be stored and carried over long distances. For the storage of water under the most favorable conditions in Arizona Mr. Lippincott estimates the cost at \$4.80 per acre foot, and as at least 5 acre feet of it must be stored for each acre in order to provide for 2 or 3 seasons of low water the cost would be about \$21.50 per acre. I would call your attention to the basis of this calculation. It assumes that all of the land that could be watered by the storage reservoir shall be actually taken up and put under water. If only half of that area is taken up, the cost would be twice as great per acre; if only a quarter, it would be four times as great, and so on. So this cost that is given in the estimates of the irrigation engineers is the cost provided all the land possible should be taken up and put under water, and the rate per acre was paid in to the canal company.

Q. What would be the value of this land after it was put under water?—A. It would be from \$60 to \$100 an acre.

Q. (By Mr. PHILLIPS.) Notwithstanding the cost of maintaining the water afterwards?—A. Yes.

Q. (By Mr. KENNEDY.) In what localities?—A. Through the arid regions. This example was in Arizona. Lands in Utah are worth from \$60 to \$100 an acre; and, set out in good varieties of fruit orchards, anywhere up to \$1,000 an acre. In southern California lands are worth generally from \$50 to \$100 an acre, but many of their orchards are worth from \$1,000 to \$2,000 an acre.

Q. (By Mr. PHILLIPS.) That would be when they were fruit bearing?—A. Fruit bearing, yes; in fine varieties of fruit. The difficulties in the way of the extension of irrigation by the construction of storage reservoirs are the alkali and the silt in the water. There is no question that the amount of alkali in the water is a very serious factor in many localities. In the Pecos Valley it has been found that the alkali increases in amount as they go down the valley to such an extent that in the lower part of the valley the water is entirely unfit for crops. In the storage reservoir in which water is stored above the town of Carlisbad the evaporation is so great that the salts become concentrated in the water, and at the end of a long dry season the water is too salty to be applied safely to the land. This region, by the way, has the highest evaporation of any place in the United States, approximately so. Considerable trouble has been experienced also and losses have been encountered by the storage of alkali waters in California, particularly in southern California.

Q. Is that water obtained in the hills and mountains or from the rivers? Do you not get pure water from the mountain streams?—A. Yes; and the water in Utah is very pure because there are short rivers that come right down from the snow-clad mountains and deliver pure water; but in the Pecos Valley the water travels 200 or 300 miles from the mountains and gathers up these salts as it goes along. The Pecos River is entirely taken up about 6 miles above the town of Carlisbad; and 6 miles below the reservoir the stream has about the same flow that it has above the reservoir. Frequently out in the Western lands the water is entirely used up before it gets down the whole course of the river, going out in seepage and flowing again into the river after it has been applied to the land. By the time it gets down to its mouth the water is pretty salty.

There is another difficulty in the storage of water in reservoirs that is particularly troublesome in some areas in the West: that is the amount of silt carried by the waters. In our work in Arizona where the waters are very heavily laden with silt, we found a soil that has been recognized as a distinct type, which is undoubtedly a sediment left by the irrigation of some prehistoric race. The old canal systems are there and the old irrigation works and the remains of the houses, indicating that irrigation was carried on in some prehistoric time, and the evidences show that this is simply a deposit of sediment or mud from the rivers. The amount of sediment is so great that the people now have great difficulty in maintaining their canals. They have already dug it out and piled it up as far as they can throw it, and it is a serious question now what they are going to do with the canals in certain areas of the Salt River Valley in order to keep them open. It is very generally believed that reservoirs will quickly fill up with the silt in such districts as that unless special precautions are taken to keep them open; and that is an engineering feature that has not yet been satisfactorily solved. In other localities there is no trouble with this silt, as the waters do not carry any great amount. Even if we get water that is free from silt and an absence of salt, there is the further danger of seepage waters and the accumulation of alkali in the soils, as I have already stated.

Q. This accumulation of alkali is only in arid countries? There is no alkali to speak of in the Appalachian Range, is there?—A. No; because the drainage is

so great. So much rainfall comes down that it is carried off. The alkali is the natural weathering of the rocks, resulting from their disintegration.

Q. Peculiar to arid regions?—A. Yes; although we have it here in the East occasionally. The mineral springs that we have are due to nothing more nor less than the decomposition of the rocks, and the same cause accounts for the alkali in the Western States. It is the weathering of the rocks being carried off by the water. In the West these decomposed rocks accumulate in the soil and stay there. Our iron springs and our alum springs and mineral springs generally are the products of the weathering of the rock being carried off by the water. But we get no such accumulations here as they get in the West, simply because we have 40 inches of rainfall here, 29 inches of which goes down through the ground and is carried off in the rivers. Out there we have a very small rainfall, only about 5 per cent of which ever goes off, and then usually over the surface of the ground.

In the consideration of irrigation as a means for the reclamation of lands, I would call the attention of the commission to the necessity of uniform State laws and the possibilities of national legislation. There are certain phases of this subject which will undoubtedly have to be taken up by the National Congress, particularly with interstate streams and where the streams form the boundaries of adjoining States. But as the Department of Agriculture has a distinct division for the study of irrigation and its laws and methods, it would hardly be advisable for me to go into it at any great length. My own connection with the matter, however, in our study of the soils and of the seepage waters and alkali has convinced me that it will be necessary to use more care in the application of water, not only conserving it for use elsewhere, but to protect from the injurious effects of overirrigation and the accumulation of seepage water and of alkali. I think it is safe to say that in nearly all the irrigated districts twice as much land could be irrigated with the water that is now used, with actual benefit to the soil, provided it was intelligently applied.

I would also refer again to the matter that I spoke of a while ago; that is, the necessity of legislation in the case of soils damaged by the accumulation of seepage water and of alkali from leaky ditches and from overirrigation on neighboring farms. It seems to me that a remedy of some kind must be worked out. It hardly seems fair or just that a person owning a piece of land which he has planted and cared for and upon which he uses the most careful and most intelligent means, should be allowed to be injured by a seepage from a canal or from the careless methods employed on a neighboring farm. It seems to me that either through State or national legislation recourse should be given for the recovery of damages in civil suits.

The next method to which I would call your attention for the reclamation of lands is the subject of drainage. There are many areas of swamp lands and still larger areas of cold, wet clays in the United States that are unproductive or have been abandoned from a small accumulation of water which needs to be removed by artificial means. It is claimed that one-fifth of the State of Michigan is swamp lands. The report of the Illinois board of agriculture for 1894 states that during 1893—that is, in 1 year—there was laid in the State of Illinois alone 26,985,000 feet of tile drains. Of this, 18,310,000 feet were laid in the northern part of the State, 8,607,000 feet in the central part, and the remainder in the southern part. In the north there were 28 feet of tile to each acre cultivated. In the central part there were 29 feet of tile for each acre cultivated, and in the southern part 1 foot of tile for each acre cultivated. In Douglas County there were 85 feet of tile for every acre of cultivated land, and in Livingston County 78 feet to each acre. In the eastern part of Livingston County is found the Vermilion Swamp. As late as 1880 lands could be purchased there for \$3 to \$5 per acre; the same lands, which have since been drained, are now valued at from \$60 to \$80 per acre for general farm purposes. As a result of this widespread system of drainage as practiced in Illinois and in Michigan, the swamp lands have become the most productive, the healthfulness of the vicinity has been much improved, and the public roads have been kept in much better repair. The drainage laws of Illinois, and in fact of most of the States where drainage is practiced to a considerable extent, are very complete and deal with all phases of the question, from the rights and liabilities of the drainage commissioners of the district down to the minute details which concern the individual. It seems to me that this question of drainage legislation is one of the important questions, at least for the Western country.

Q. What State has the best laws as to drainage?—A. My opinion is that Illinois has the most complete; Illinois, Michigan, Ohio, Wisconsin, Minnesota, and New York.

As a result of our soil investigations in the Salt Lake Valley last year, we found that it would be quite possible to reclaim the large tract of salt land west of Salt Lake City, and perhaps that this should be done by the people; but it was appar-

ent in the first place that if it were done it would have to be done by private enterprise, as the State was debarred by its own constitution from taking any part in internal improvements of that character, as is done in Minnesota and in some of the Central Western States. It was further found that, by reason of the lack of any drainage laws, it would be almost impossible to drain any considerable part of that area without getting the written consent of every individual land owner who would be in any way affected; and strange as it may seem, it was not found possible to get such consent in the attempts that have been made.

Another method for the protection and reclamation is by levees for protection from floods and from tide. The commission of course is aware of the important work of the commission having this matter in charge on the Mississippi River, and it is scarcely necessary for me to refer to it at this time. I have also spoken at some length in regard to the levees protecting the rice swamps of South Carolina and adjoining States.

A question that is assuming some proportions now in this country is the possibility of reclaiming the swamps of the Atlantic and Pacific coasts. Not only is it desirable to reclaim these lands for their agricultural value, which it is admitted would be great, but for the protection, the help, and the material welfare of the surrounding country. We have a very excellent illustration of the tremendous bearing this question has upon the healthfulness and prosperity of a community by reference to the conditions prevailing here in the city of Washington, where the swamps have rendered almost uninhabitable, at least to the wealthy and well-to-do people, certain portions of this city, and where there is no possible question that the cause could be removed, and an appreciation of property aggregating thousands and thousands of dollars could be effected simply by reclaiming the swamp lands.

Q. Have you any method of or any theory concerning the reclaiming of those lands? The tide comes up the Potomac. How can it be prevented from overflowing?—A. The same method would have to be used that is used in the rice lands of the South, where similar conditions prevail. There should be a levee with gates which will let the water out and drain the land, and will shut when the tide comes up and prevent any access from the outside. With that protection against the rise of the tide, accompanied by the necessary drainage in the soil itself to carry off the seepage waters which come from the surrounding country, the land could be reclaimed and put in a high state of cultivation.

This question has been asked in regard to the possibilities of reclaiming many of the marshes of Long Island and of New Jersey, particularly. It has been estimated that the reclamation of the marsh lands in New Jersey adjacent to Jersey City would cost something like \$3,000,000. The plans are under consideration now, and, in fact, large areas have already been undertaken in the reclamation of those lands. Also along the coast, particularly in connection with the residents on Long Island and along the Jersey coast, in Delaware and in Maryland, and in North Carolina and in Virginia, the disastrous effects of these swamps are keenly felt by the people who go there to spend the summer near the seashore. Not only are they unpleasant, but they are at times and in places distinctly dangerous because of the prevalence of mosquitoes, which convey malaria, and because of the presence of other fevers that are very fatal or injurious.

A plan has recently been proposed to the Department for the reclamation of a large area of swamp land on Long Island for the purpose of being able to treat the swamp for mosquitoes. They are not able without enormous expense now to control the mosquito pest and the consequent malaria that has come to the locality. They want to see if the land can be diked and subsequently drained so that they can entirely exterminate the mosquitoes from that locality. It is probable that the plan will be carried out.

It seems to me that such work as that is primarily for the individual and in the second place for the State. I hardly see that the National Government has any interest or control in the matter. It is certainly not like the development of harbor privileges or the improvement of rivers, for it applies only to the locality in which it is conducted.

Q. (By Mr. CLARKE.) Are you aware of the experiment in reclaiming marsh lands that was made in Marshfield, Mass?—A. Not particularly.

Q. There the dike had the effect to close the harbor, practically; not but that there was sufficient area of harbor below the dike, but the failure to accumulate a large body of water above that checked the passing out with the ebb of the tide, and resulted in the accumulation of sand bars in the lower harbor, so that the harbor was practically ruined, and there was a great clamor on the part of the fishermen, which finally came to be supplemented by that of cottagers who built along the shore of that small bay, until, finally, the legislature was induced to cut away

the diking and abandon the experiment of reclaiming the lands.—A. Oh; it was the outflow of this immense volume of water that filled up the channel?

Q. Yes; so I apprehend that whenever the experiment is entered upon along the shore anywhere to reclaim the marsh lands the question of harbor rights and the like will come in to affect the problem more or less.—A. There is no question that legislation will be necessary, and it is likely to be a complicated matter. It is one that would affect the State, however, and not the National Government, unless it interfered, of course, with the channels of the harbor; then it would be a national matter.

I think that I have covered in these remarks the principal causes of the exhaustion and the deterioration of soils, as I view the question, and I have spoken at some length in regard to measures which should be used for the reclamation of lands. If I have left anything unsaid that should have been said, or if I should have made anything clearer, I should be very glad to answer any questions that the commission may be pleased to ask.

Q. You said something about animalcules in the soils. Is that a comparatively recent discovery, or has it been long known to scientists that soil abounds in animal life?—A. It is comparatively recent, that is, within 30 or 40 years, that the bacteria have been recognized and their importance understood.

Q. I have seen a statement that you can take a small tract of soil which is very fertile, and accustomed to produce large crops, and strike it with a pole persistently until you kill all the animal life that there is in it, and that the next year it would not bear anything. Is that correct?—A. I do not think so; I do not think it would be possible to kill bacteria in that way.

Q. (By Mr. PHILLIPS.) You spoke of cultivating bacteria. What process is used?—A. Certain leguminous crops have tubercles on their roots, which are found to contain large numbers of these bacteria, and by inoculating with this suitable culture medium, they can be cultivated and pure cultures be made. Such cultures are for sale in Germany and, to a limited extent, in this country, and it is found that certain crops will not grow unless this bacteria is in the soil; therefore many of the leguminous crops, for example clover, will not grow unless there are certain forms of this bacteria in the soil, and by seeding this pure culture over the land, that is mixing with a little soil, and sowing on the land, the yield may be doubled, or increased even more than that.

Q. The small bulbs are used in producing cultures in the same way?—A. Yes; the tubercle is just mashed in the culture medium, so that the inside is exposed, and these bacteria get out and thrive on this culture medium.

Q. What is used for that culture medium?—A. I am not sure what is used; I am not acquainted with the method of making the pure culture.

Q. (By Mr. TOMPKINS.) That is similar to Conn's culture in giving flavor to butter?—A. To butter or cheese.

Q. Where is this culture made in this country?—A. Some important experiments have been made at the experiment station in Alabama.

Q. At Auburn?—A. At Auburn; yes. Some of the most important work has been done there.

Q. Under whose charge?—A. I do not recollect now.

Q. (By Mr. CLARKE.) Can you ordinarily determine by the examination of soil what is requisite to make it more productive?—A. No; you can not; and that is one of the most embarrassing questions that we have to answer. As I have shown in my testimony, the cause of the deterioration is quite often due to lack of good management, good judgment, and good practice on the part of the farmer, but we can not tell from a chemical or physical examination whether the soil is productive or not. We can often tell the kind of crop it is adapted to, whether it is a truck soil, or wheat soil, or a grass soil, but whether it is fertile in its condition the chemical analysis does not clearly indicate.

Q. Recently Mr. Hammond, of South Carolina, a very intelligent planter of long experience, testified before the commission that in his opinion the use of commercial fertilizers was an evil rather than a benefit, especially in his State, and particularly because it led many farmers to abandon making an application of the ordinary farm fertilizers, manures, etc. What is your opinion about that?—A. My opinion is that in the main that is correct; that the use of fertilizers tends to make the farmer more shiftless and less careful in saving, and in the cultivation of his land. Fertilizers have been introduced in comparatively recent years. There was never any trouble for lack of fertilizers in the Eastern countries. The lands there have been cultivated for hundreds and thousands of years, but it had been done by careful work. The farmers have saved everything that came off the place. They have saved all of the litter and put that back; all manure and put that back, and all excrements and waste of the farm

and put them back on the soil and worked it in; they have had small holdings and used intensive cultivation. With us, we have these large areas, entirely too large to manure with the ordinary waste from the farm, and we rely on these commercial fertilizers with no addition of organic matter, and often with clean cultivation. There is no question in my mind that much harm has been done by continuous and excessive use of commercial fertilizers without the intensive methods that should be employed when they are used.

Q. Would it not, in your opinion, be possible to reclaim very many of the so-called worn-out farms of Maryland and Virginia by gathering manure from the low places and subjecting it to the tread of live stock, and mingling with it the manure that ordinarily accumulates on a well-stocked farm, and applying that intelligently to the various soils of those farms?—A. It would be where the cost of the process would not be too great, but unless it was adjacent to the land it would not be feasible. The cheapest method in that case would be to grow cow-peas and other forms of green manure. There is no question if you adopt such methods as that, of being able to bring the land up. It is simply because farmers do not do what they know is the simplest and most efficient thing to do. There are lands that are kept up in good shape just by the methods that are used on the average farms, which are in very good condition, simply because they are attended to in those ways.

Q. Have the farmers of the West begun to practice fertilization a great deal more than formerly?—A. They are not using fertilizers to any great extent. I think the practice is increasing a very little, but very little fertilizer is used throughout the West at the present time.

Q. Is there not danger that their soils will become comparatively barren unless something is done to restore what is taken from them?—A. There will be if the owners persist in the cultivation of the same crop year after year, as is done now in Red River Valley and in some of our Central States; but by a rotation of crops or by introduction of more intensive methods when the soils begin to wear out their fertility can be maintained and improved. Now, they say very justly that while they are getting 12 or 15 bushels of wheat to the acre at the low cost at which it is produced, 20 cents, they don't care at all what becomes of their lands; they are going to last the lifetime of the present generation and they are not concerned with what becomes of them after that. I think very likely that that yield of 12 or 15 bushels that is obtained now in the Red River Valley can be obtained for a long series of years. The soils are almost identical with the fertile wheat lands of Russia that have produced wheat for a great many generations, but the time will come, I presume, when the yield will decrease below what they are getting now, and they will feel the need either of fertilizing the soil better or of changing their crops and introducing more intensive methods than they have at present.

Q. What is your advice on the subject?—A. I see no opportunity of changing the methods at the present time. It is a good deal like the arrangement made where you can rent range lands for 5 cents an acre per year, and where you can not afford to put much improvement on the lands. They are only worth \$1.25 an acre, and you certainly can not spend much money in maintaining the fertility of such lands. It seems to me it is an economic question; it is not an agricultural question. We simply can not afford to maintain the fertility of those lands with the expense attending that process until lands become more valuable than they are at the present time.

Q. It is cheaper, is it not, to maintain fertility than to restore it?—A. That, of course, is a relative matter; it is more expensive for us and it is less expensive for our grandchildren.

Q. Have you investigated the subject of flowing sewage upon the lands?—A. I have not, except quite incidentally. We have never made any investigation of that question at all.

Q. (By Mr. PHILLIPS.) What is the best green crop to raise to fertilize the land—plowing it down, for instance?—A. Clover is one of the best renovators of the soil where it can be grown, but the possibilities of growing it are limited and the most generally useful crop is the cowpea of the South.

Q. That came into use quite recently?—A. Yes; well, 25 years ago in an extensive way.

Q. Is it used to a considerable extent in the North and West?—A. It is being used to a considerable extent now in the North.

Q. It is supposed to have this bacteria, is it not?—A. Yes; it has these root tubercles.

Q. (By Representative BELL.) Have you ever visited Greeley in Colorado?—A. I was there once, 6 years ago.

Q. They have a rotation there on first wheat; then they follow with alfalfa, which they plow under; then follow with potatoes, and in turn follow the potatoes with wheat. They thus grow an enormous crop every year. I think they make over 40 bushels of wheat there to the acre following those crops.—A. And they get enormous yields of potatoes.

Q. Enormous. It is the best potato spot in the world. They haven't a rival in the United States. I think they ship the best potatoes to London.
(Testimony closed).

BOSTON, MASS., February 19, 1901.

TESTIMONY OF HON. J. W. STOCKWELL,

Secretary of the Massachusetts State board of agriculture.

The special subcommission met at the Home Market Club at 10.30 a. m., Mr. Clarke presiding. At that time Hon. J. W. Stockwell, of Sutton, Mass., secretary of the State board of agriculture of Massachusetts, was introduced as a witness and, being duly sworn, testified as follows:

Q. (By Mr. CLARKE.) Please give your name and post-office address.—A. J. W. Stockwell; State board of agriculture, rooms 134-136, Statehouse, Boston, Mass.

Q. Are you the secretary of the State board of agriculture?—A. I am.

Q. How long have you held that office?—A. Since July 1, 1899.

Q. (By Mr. A. L. HARRIS.) Previous to the time of being selected as secretary of the State board of agriculture what had been your occupation?—A. I am a farmer. I have always been a farmer, in connection with other business. I have been a member of the State board of agriculture for 6 years, by appointment of the governor, and have been connected with the Massachusetts State grange as a State lecturer for 6 years. From the time I was in the State senate, in 1879 and 1880, I have had more or less to do with matters of legislation in the interests of the farmers.

Q. Were you engaged in general farming or some special line?—A. General farming rather than special lines, except as a breeder of Devon stock.

Q. You have before you the plan of inquiry of the commission. You can take up the topics and answer them in your own way.—A. I will take each question and answer it as well as I can on the basis of the State of Massachusetts. On question 1, "Increase or decrease in number employed in agricultural labor in the several States during the past 50 years." I have found for Massachusetts: 1875, 74,500; 1885, 77,661; 1895, 37,556. This last, 1895, is on a different basis. It is exclusive of agricultural laborers, and therefore of no relative value. I think that the percentage of the previous decade will hold good, that there has been no lower number.

2. "Comparative condition of those so engaged." Better conditions in the farmers' homes all over the State, and, so far as these have influence, a higher plane of living. The progress of agriculture, the influence of the State board and its institutes, the work of the grange, the progress in all other lines are reflected in these advances. The laborers on our farms enjoy better conditions of life than formerly. It is our endeavor to keep the rural homes equal to those of the same class of citizens in our villages, with all conveniences and comforts found there. The surroundings of the home are more neat and more beautiful than they used to be. It is to this end that we protest against the undue burdens that take from the comfort of the farmer's home by taking from his ability to furnish these comforts because of reduced revenue or greater expenditure, whether caused by monopoly and higher prices or by undue and disproportionate taxation; and to this I shall refer later.

3. "Effect of improved machinery on labor." Its natural effect is to raise the quality, as more intelligence and skill are required for its profitable use. Yet this is offset somewhat by the different quality of labor seeking our shores. On this point I will refer you to a printed lecture before the board of agriculture, December 4, 1900, which I have not with me but which will appear soon in our report, on "Some lessons from the census." It was delivered by President Pritchett, of the school of technology, before our winter meeting of the board, and it is very instructive as showing that our early immigration was English, Irish, Scotch, and German, a valuable addition to our intelligent citizenship, while now the immigration is Polish, Italian, Finn, and other races not so high in the scale of intelligence. This we have to contend with, though these are more largely drawn into other pursuits and do not come to the farmer so directly.

4 and 5. "Causes of irregularity of employment," and "Transient labor in busy seasons." The wide-awake farmer will hire all the help he can with profit, and no more. When profits cease he will be the first to discharge help which he does not need.

Q. Where does your transient labor that you use on the farms in the busy season come from?—A. Mostly from our manufacturing villages, going about and asking for an opportunity because in busy times, like the haying season, they get better wages on the farm. In fact the farmer pays better wages than the manufacturer, and his desire to use help is regulated by his expectation of profitable returns from his work. As in any other line of business, the wide-awake farmer will adapt himself to the conditions of the season and the markets.

6. "Hours of labor in different agricultural pursuits." Ten hours is the legal day, and it is very carefully and very generally observed. The hours vary slightly in different cases, as on milk and vegetable farms, where there are persons paid in accordance with the length of day, they being hired with that understanding.

7. "Average number of days employed in the year." By the month help is hired for 8 or 12 months, either for the busy season of 8 months or for the entire season of 12 months. By the day it depends upon the character of the help and the necessity for hiring, and the ability of the worker. If a man is a good worker he usually finds work at all seasons. The farmer realizes the value of good help.

8. "Tendency of agricultural labor to seek other employment; causes and remedies." Farm life is secluded to a certain extent, and there is to-day a great desire to huddle in the larger centers; and while, as I said, 10 hours is a day, nevertheless it must be a longer day—not necessarily more hours, but the early feeding and the later care make it a longer day. For instance, from 6 to 7 o'clock, feeding and chores, 7 to 8 breakfast, and then 8 to 12 work, is only 5 hours, but still it is a different line of hours from those of a man who goes into a mill and begins and finishes his day's work with no reference to the care and feeding of stock. Then, another reason is that it is a "strenuous life," to use a present expression. It is not sitting on a stool and watching and guiding machinery, but strong, healthy labor. Too many prefer the stool, or, if life must be strenuous, wild-cats and wild oats are more attractive. Good, hard labor is not as attractive as it used to be, I fear.

9. "Wages and methods of payment. Daily, weekly, monthly, or yearly payments." Monthly, generally. Employee may draw on account and settle at the end of the season, and perhaps leave a little balance in the farmer's hands, so it shall accrue during the season; but I think the payments are generally made monthly. That is preferred by the employees; of course they can have it more often if they desire.

10. "Maximum wages; minimum; average, in different branches; in different States and sections." I am speaking only for my own State. It depends on the quality of help and the season of the year. By the month, with board, \$16 to \$25; without board, \$28 to \$35. Some few obtain higher. By the day, \$1.50 to \$1.75.

11. "Cash payment, store orders, payment in kind." Cash payment generally; nearly always cash payment. I do not know that there are any exceptions in Massachusetts to-day unless it is in the matter of corporations, and I think even there other methods are forbidden.

12. "Tenant houses and tenant-house allowances." House rent is always considered in making your price with an employee. If you have a tenement and he wants to live in it, he is supposed to pay you rent just as he would anyone else.

Q. In regard to the allowance of a house, usually, does that include the garden-truck patch, a cow pasture, or anything of that kind?—A. Yes; but, of course, the payment is conditioned upon it. The better the conditions granted the greater will be the payment.

Q. What is the character of the tenant houses?—A. For the farmers, generally good. So far as I know, in our section they are always good. Of course, a man has the choice of a tenement, and the farmer is glad to have good help, and so he is ready to do what he can for his help, that he may have good help.

Q. (By Mr. LITCHMAN.) The house he lives in is on the farm?—A. Not necessarily.

Q. In the village near the farm, or how?—A. With mine, my foreman now has his own farm, or house with a garden and small farm, and yet because he suits me he works for me, though I have a tenement right in the center of the village, a two-story house in very good condition.

Q. This is located in Sutton, your home?—A. At Sutton.

Q. Is the amount necessary to pay for the rent of the tenement considered in fixing the compensation between you?—A. Yes, certainly; if my house, with a garden, is worth \$4 per month, it is considered, in the amount paid per month, as a part of the price.

Q. Is it the custom for the help, in some instances, to live at the farm in the house, or adjoining the house, of the owner of the farm?—A. Very frequently. There are many farmers that desire to board their help. They prefer single men and board them, so as to have them right at the farm and right at hand. It is the general preference with a farmer to have his help right under his care, and they are well cared for, I think.

13. "Crop sharing, partnership, tenancy. Practicability and present status of these methods." 14. "Loans to tenants, liens on growing or prospected crops; extent of; effect of." I do not know anything about the thirteenth and fourteenth questions. I think there is very little crop sharing in Massachusetts, and I had not heard of such a case as would be called real crop sharing, except single fields, or in a small way. Sometimes a man makes an agreement with a farmer to raise a crop for him, takes it on shares, but it is so infrequent as to have but little effect on the status of farming operations.

15. "Immigration and education. Nationality and character of foreign immigrants." The lecture which you will have by Dr. Pritchett will give you a very good statement, but we were not able in our report to put in the illustrations by chart which he gave in his lecture of the classes of immigration. We could not afford the price and the State would not allow us to do it; but it shows very plainly that the early immigration was, as I have said, from the very first settlement, of rather a higher class, which has built up this country, and that the present immigration is from a different section and is of a different character.

Q. (By Mr. A. L. HARRIS.) Is there a disposition on the part of the immigrant to go to the farm?—A. The immigrant class comes over and takes the first labor at hand, and that is usually manufacturing or mere laborer's work. If our large corporations will bring over immigrants, going around the law, and these immigrants are able to do that kind of work for which they came, that is their first work, and they come here for a low price to do it; but as they get used to our prices and increase their price they leave the work for which they were brought here and drift into other lines—farming, for instance.

Q. When they do drift to the farms, do they make as good farmers as the older immigrants?—A. Some of them do make very good farmers. The Swedes, for instance, are a very good class of workers and citizens, and some of the Poles have done very well. There are also some that we very seldom see on the farms. The Italians are seldom on a farm, I think, in Massachusetts. They are very good workers, but they find work in other lines, and desire it. They are very much inclined to congregate together.

17. "Tendency to colonize—to preserve foreign customs and languages." I do not think, so far as my knowledge extends, that this tendency is general in Massachusetts. Foreigners desire to congregate rather than to colonize. The children attend our schools and learn our language and desire to associate with the children of our people. The French Canadians very soon after they come here become naturalized and take active part in town, county, and State affairs.

Q. Has the pupil a desire to learn the English language in preference to the native tongue?—A. I presume so. We do not have a sufficient number of immigrants coming here to furnish any opportunity for them to do otherwise than go into our schools, except in the parochial schools, and there we have a certain oversight. They must learn our language so as to become good citizens.

18. "Effect of such immigration upon American agriculture." The thrift of the New England agriculture is in the home market for our products. We have certain lines of agriculture which we can make profitable and certain others that we can not, and the home markets for our products are the sources on which we must rely for our profits. The labor of New England is the consumer. Whatever these people do, they eat, and they usually have large families, and the farmer and the market gardener are the gainers. It is well understood that the more people and the more industries and the more prosperous those industries the better it is for those who furnish the home market products. This diversifies our farming, draws it from the old lines into more profitable channels.

Q. (By Mr. LITCHMAN.) You find, then, the proximity of the farm to the factory valuable to the farmer?—A. Oh, very.

Q. By diversifying the product?—A. By changing the product almost entirely. The old lines of agriculture have passed away near these centers. It is the market garden and the improved methods that are now of profit to us, and because of this New England agriculture is more profitable to-day than it was a few years ago. This is certainly true of Massachusetts.

19. "Suggestions as to regulation of immigration." I said upon this that the cheapest labor in Europe, and in Asia to a lesser extent, is now brought to our shores for the benefit of our corporations representing the mining and railroading interests of the country. The influx is not as great as it was a few years ago, so

we are reaching after the cheap labor in the islands of the sea. It is a part of the commercialism of to-day. The cheaper the help that can do the work the more they are sought for by our great corporations. I am not speaking particularly of Massachusetts now, but rather of the spirit of the age.

20. "Colored labor, extent of." There is a very small percentage, and that is mostly in cities; only a small extent on farms.

21. "School age of children in the different States." The compulsory age in Massachusetts is 7 to 14 years, and the law is very generally enforced. We have the State board of education and our State police for the purpose of enforcing the school laws for compulsory education. I think they are doing a good work and are fairly successful.

Q. (By Mr. A. L. HARRIS.) Is your law well enforced?—A. Very well enforced, I think.

22. "Sufficiency of public-school facilities; per cent enrolled." I am not prepared to speak of the per cent enrolled, but the public-school facilities are generally sufficient. The quality in some of the hill towns, where the taxes are most oppressive, is not of the best. Appearing before a committee at the last session of our legislature with reference to assistance for the country towns in the cause of education, it was rather sad to hear the reports from some of the educators in the western part of the State, in the hill towns, as to the conditions there and the necessity for taking the farmer's daughter, educated in those schools and in that limited way, as teacher because taxation was so severe. The taxation for school purposes in the towns and cities of Massachusetts varies from \$1.05 per thousand in the richer centers to \$9.75 per thousand in the sparsely populated hill towns, and this notwithstanding the best possible distribution of the small State fund now available.

Q. Have you any provision for the farmer's boy or girl obtaining high school privileges at the public expense?—A. We have high school privileges in every town, and there is a law at the present time, I think, that furnishes transportation to the school. If there is no high school in town transportation is furnished to the neighboring high school. I have no exact knowledge of the law, but it is amply sufficient.

23. "Adaptation of public curriculum to the needs of the agricultural people." There has been no special adaptation that I know of until just now nature studies are being introduced. So general is the knowledge required of the farmer of to-day that the common schools can only supply the foundation, and this must be general. I do not know anyone that needs more a technical and thorough knowledge than the farmer, in order to understand his soils and his work. Each farm has different varieties of soil, and how best to apply the fertilizers to meet conditions of soil, and what fertilizers and crops will make the best return, requires careful study. It requires an education that can only have its foundation in the public schools.

Q. Is there any effort made on the part of the farmers' clubs or farmers' organizations to have object lessons peculiar to the farm introduced in the common school?—A. I do not know how largely. We are sending out nature studies, leaflets, and they are supplied to the schools in such number as they may desire when called for. I think within the last two or three years there has been a marked advance in the matter of interesting children in nature studies, with good results.

24. "Technical education." Technical education is very important, and the State agricultural colleges are doing a grand work in sending out those who are lecturers and teachers in agriculture by example as well as by institute work. Any force that gradually uplifts the people is never appreciated except by the careful observer. From the standpoint of 20 or even 10 years ago, there has been a great advance, partly at any rate, and I believe largely to be attributed to technical and experimental education.

There is one thing not included in our schools: Our education covers so many weeks in the year, and is so arranged that actual hard work does not enter into its curriculum, and good, honest hand labor is something the boy and girl do not know until they get beyond 15. After that they do not think it wise to take it up. So the idea of good, hard manual labor does not enter into life and is falling into disuse, I fear. Costly athletics take the old place of honest work, except at our agricultural college, and there "sports" must be encouraged or we lose students. So our boys are in it, and we want them to make a good record.

25. "Total capital employed in agricultural pursuits." The total capital employed in Massachusetts in 1895 was \$219,557,314. I have no later figures.

26. "Earnings of capital compared with 40 years ago." I have thought of this a good deal, but I am not able to make an answer that is satisfactory to myself. Perhaps it is equal; it should be more. To keep abreast of the times costs more

than it did a few years ago. The farmer can not afford to fall behind, nor can the country afford to have him.

Q. You might take a more recent period than 40 years.—A. It is unfortunate conditions that have depopulated our farming towns. Forty years ago the hill towns were engaged in various manufacturing enterprises. The land was well and regularly laid out in fine farms. Business of all kinds was prosperous. The farmer was making money, and, better than all, was bringing up children who were destined to spread abroad throughout the land, and whose influence, as I have said, is now felt throughout the Union. It was no sudden movement that reduced the population of these hill towns.

The general story of a great agricultural decline is, however, only half the story. The decline of manufacturing industries in the hill towns more than equals the decline of agricultural industries. The proportion of abandoned wagon shops, shoe shops, sawmills, and other small mechanical businesses, which were once the life of flourishing villages, has kept pace with, and indeed far outstripped, the abandonment of farms; and much of the so-called decadence of the hill towns is due to the changed methods of manufacturing industries, taking away the work that was scattered through these towns and concentrating it in the larger plant and the improved machinery of the stronger combination, and thus drawing the workmen to the larger towns and railroad centers.

I shall touch upon some of these unfortunate conditions later as I proceed.

28. "Taxation of agricultural property." Taxation is one of the world's unfortunate conditions toward agriculture. In speaking of this decline before the farmers' congress I showed how the decline, as reported in the State of New York, and as reported in the State of Connecticut, is regarded. In New York the result was summed up with the statement that farming had very seriously depreciated. I quote from that report: "Farming land had depreciated at an average of 48 per cent; that 30 per cent of the farmers are anxious to leave their homes and would drift into the city if they only knew how to get work there; that 86 per cent of the farmers report that their children as they grow up can not be influenced to remain on the farms; that tenant farming is on the increase; that 35 per cent of the New York farmers are losing money; 50 per cent dangerously near it; 14 per cent making a profit, and 20 per cent do not know whether they are or not." That is a report made to the New York Society for Improving the Condition of the Poor. These figures are significant, and they were compiled at a great deal of expense and with great care. I suppose you have that report before you. I then took the farms in Massachusetts to show something of the same thing. By studying the census returns we find the following data:

	1880	1890	Decrease.
Number of farms.....	38,406	34,374	4,032
Number of acres.....	3,359,079	2,998,282	360,797
Valuation.....	\$164,288,956	\$146,197,415	\$18,091,541

These are hard facts and not theories—facts that have had much to do with the welfare of the country, and will have more unless changed.

In speaking of taxation, I say it is one of the unfortunate conditions. The farm is seen and taxed. There is no escape from it. Probably from 1,500 to 2,000 millions of wealth in intangible form escapes taxation in Massachusetts. If that is a fact, it would lower the taxation of the farmer very greatly if it were remedied. Of course, the double burden falls back on the productive industries, and most heavily on the farmer. The farmer asks no exemption, only equal taxation, according to ability.

Under the same head, it should be stated that the school tax is not entirely for the benefit of the town, but of the State. The roads are not entirely for the benefit of the town, but of the traveling public; but the taxes are all on the town.

Add to these the removal of the industries, taking away population and wealth, and there is a heavy burden the farms can not support. The State lays these burdens without mercy, but touches them not with an adequate hand.

Third, it seems to me there should be national agreement or national control of corporations, or corporation laws if there can be. Massachusetts has the best corporation laws of any State. Honesty is the foundation stone, and honest returns are enforced. Our people, desiring a little water or a little fraud, and with an earnest desire to cheat the government in taxes, just step into the adjoining States and come back with a Maine, Delaware, or New Jersey charter; and Massachusetts business is carried on in our cities and towns outside the control of

the tax commissioner of the State. They receive all the advantages and protection of the laws of the State and contribute nothing.

Those are three of the ways in which taxation has laid very hardly on the farmers. And let me say, the decline in farm lands in Massachusetts is consequent in part upon the removal of industries to the large centers, as I have already said. In the old times, 20 or 40 years ago, every part of a town was alive with little industries, and on every water privilege was a mill or some little manufactory. The shoe business was done in the towns, each center being a manufactory, the farmers, or the young people in the farm homes, doing the work. This all brought to the town a certain amount of life, a certain home market, and a certain amount of money, and everything was prosperous in the town until that industry moved away to the larger center. In the natural course of events it took with it these young laborers. It took with it the support given to the church and the school, and in consequence the farmer had the whole burden to bear, adding very greatly to his taxes; and more than that was the discouraging fact that his sons and daughters went away, and he was left alone. That led to his going after them and the farm being abandoned. Really, I think the beginning of the decline of New England agriculture dates from the concentrating of the industries in the large centers and the withdrawing from the towns of the aid they naturally gave to the support of society in all its lines.

Q. How is your property valued for taxation in Massachusetts?—A. It is intended to be assessed for its exact value. In our farming communities I think the real estate is valued in some cases for more than it will bring at forced sale. At any rate, we find it so when auctions occur.

Q. No margin is left, then, on the part of the assessor, but he values it on account of its being visible and tangible.—A. Not intended to be. Their oath is to assess a true value.

Q. Is your assessor elected or appointed?—A. Elected by the people of the town.

Q. Is that method better than to appoint by some authority and remove him from the influence of the elector?—A. We think it would be far better if he were so removed, and if I were at the State House, I would be advocating the change now before the committee on taxation of the present legislature. Even one man, in one of our towns, having large wealth and being prominent, can insure the election of an assessor to his liking, or endanger the election of an assessor who does his duty. The rich influence the assessor in two ways, by threatening to leave the town and by putting the honest assessor out of office. In speaking of taxation with a gentleman well known throughout the nation, he said: "Mr. Stockwell, do all you can; the poor always have paid the taxes, and they always will." I do not want to believe this will be the everlasting condition of the foremost Christian nation, or its standard of justice, saying nothing of the finer qualities that are supposed to be included in that word "Christian."

Q. Who fixes the rate of taxation?—A. The town in town meeting; at the annual meeting the people fix it. That is not decided by any moneyed interests. Every voter has an equal right to a voice in the town expenditures.

Q. (By Mr. LITCHMAN.) Is not the rate of taxation fixed by the board of assessors?—A. The rate of taxation is, but the appropriations are made in town meeting, and the rate must cover the appropriation, so that it really goes back primarily to the town meeting. The town really fixes its rate in the annual town meeting by its appropriations. Of course, the State and county tax are included also in the assessment.

Q. (By Mr. CLARKE.) Is farm land in and near cities and towns that is really held for building lots appraised at its full value?—A. I do not know. I am talking to-day more of the country town. I think when you get near the cities and large centers it is a very difficult thing. For instance, the taxation committee of 1893 traveled over the State to find out the condition of the people. They came back recommending a change something like what has been suggested. We found in going through the western part of the State, about North Adams and Williamstown, the ordinary farmers dependent on their farm crops in the outer sections were really oppressed by taxation. The amount of wealth that had come in there demanded so much and so many improvements, while their returns for their crops remained the same, so that it was a burden to them. We went down to Pittsfield and met the farmers there, and to Lenox, where they are very proud of their town, and it is a perfect paradise of beauty. The burden, after all, has fallen upon the farmers in these towns because the town is obliged to do so much. They are proud of the town, of course. They do not want the wealth and beauty to go away, and yet they want some relief from the taxation that is driving them out of it because of the increased demands upon them in many ways.

Q. Is Lenox a great summer resort for wealthy New York people who own large estates there?—A. They own large estates that are given up to beauty. There are lawns of 50 to 100 acres that are marvels of beauty. Newport does not compare with it at all.

Q. Has not the real estate valuation of the town of Lenox increased in consequence of those improvements?—A. I think not as it should have done. I do not know why. It is this way: Here is a man that has a farm from which he is getting his livelihood. It is right adjoining another piece of land which is not by nature any better. The one you tax for \$1,000 an acre, and if you tax the other for \$50 an acre you are oppressing the owner, the farmer. Therefore, these acres on which thousands have been expended are not taxed on that basis. I am only giving you the facts as they came to us at that time.

Q. (By Mr. A. L. HARRIS.) Is your State government partly supported by direct taxes?—A. To a certain extent.

Q. What is the proportion between the amount assessed by the State and the amount assessed by the locality—that is, the county and town?—A. It depends on the town and the extravagance of the people, or the demands of the people rather. The State tax may be \$2,000, the county tax \$1,000, and the town tax \$12,000. I should think those proportions would be fair. I am simply giving you an off-hand guess at it, but from my own town and my acquaintance elsewhere I should think this a fair statement of the proportion.

Q. That \$12,000 is used for the benefit of the town, of course?—A. For schools, roads, the poor, very largely. These are the three appropriations drawing most heavily on the towns, the main items, and it seems to us that in all of them the State is somewhat interested.

Q. Have you any suggestions to make as a remedy for the conditions that you have described, further than the one you just suggested a moment ago in regard to the assessor?—A. I think if we could have a fair assessment of all property that it would so reduce the assessment on farming lands that there would be no necessity for other measures. I think it would have a great effect. I do not think the school should be a matter entirely, or nearly so, for town tax. I think the State should take a greater interest. Perhaps you know Massachusetts as a State gives in proportion the least of any State in the Union, excepting New Hampshire, for the benefit of schools. The towns give very largely. I am referring to the State as a State. The towns support the schools and the laws of the State obliges them to do so.

Q. Without that qualification your statement may seem strange to outsiders where the aid is from the State.—A. That should not be, for the amount contributed in the State of Massachusetts for schools is very liberal: the towns give beyond their ability for the schools. In fact, it is one of the things of which Massachusetts may be proud—the way in which the people of her towns will tax themselves and deny themselves that their children may be educated. One of the things that leads the farmer to give up the country home and go to the city is the education of his children. The following are the figures in regard to taxation for school purposes in Massachusetts:

Massachusetts school fund, 1900	\$4,370,548.14
Income, 1900, expended yearly	213,066.18

Half of this income goes to 250 towns and half to general educational expenses, or about \$100,000 annually to the country schools.

Amount of money raised by annual appropriation for the support of schools in the cities and towns of the State

Valuation per pupil:

Highest (Nahant)	42,921.00
Lowest (Gay Head)	728.06

Tax for support of public schools, per thousand:

Highest, 1899 (West Boylston)	11.09
Lowest, 1899 (Nahant)	1.18

Percentage of tax expended for support of public schools for 1899–1900:

Highest (Wilbraham)65
Lowest (Hull)08

Amount raised by taxation for support of public schools for 1899–1900:

Highest (Nahant), per pupil	50.77
Lowest (Middlefield), per pupil	5.12
Gay Head, per pupil	3.21

Q. Does the State of Massachusetts compel the towns and cities to provide free text-books for the pupils?—A. It does. It also compels us to have 40 weeks of schooling each year, and it compels us to have a proper corps of teachers, so far as may be.

Q. This provision for free text-books applies to all, including the high schools?—A. Yes. And there is a bill before the legislature now that the text-books shall become the property of the pupil; not only for his use in school, but his property.

Q. To take away when his school year ends?—A. Yes; and I am in favor of that. The old text-books which I studied are the ones I refer to now, although there are doubtless much better ones.

Q. Are colored pupils permitted to go to the white schools?—A. Certainly; there is no distinction.

Q. You raise a State school fund?—A. We have a school fund which has been funded for a long time, and the interest of which is distributed to the schools. Then we have a small fund or tax which is raised each year, and that has been added to the other amount.

Q. How is that distributed, according to school youth?—A. As far as maybe—of course there are exceptions—to the weaker schools and the towns where the taxation for schooling is most burdensome. It is intended to cover that point. Of course, in making any general law there must be exception, but the point is to benefit the weaker towns. We have some of us felt it should be increased, and have asked for a half-mill tax in favor of the country towns, and we carried that proposition through the legislature 3 years ago. It was vetoed by the governor. That has been the distribution as far as it goes. We simply proposed to add to it one-half mill, and our law of distribution was based on the average attendance in the schools. As you see, while Boston would get its proportionate share of this tax, it would not get all that it contributed, and this would hold good in the richer towns and those most favored as to tax rate. It would be distributed according to average attendance, and Boston would annually contribute about \$500,000 to benefit the poorer towns and the State at large. But we realize that Boston, on the other hand, is drawing every day not only the money of the State into its coffers, but the best manhood and womanhood of the State, and therefore she gets her return for this loss in a higher manhood and womanhood and a better citizenship.

Q. (By Mr. LITCHMAN.) The school fund is augmented by minor taxes added to the school fund?—A. Yes; the dog tax is added to the fund; and in our town there is an old parish gift which comes in to augment the fund, given by some one years ago to be annually distributed.

Q. Are there any statistics that would show the total amount per capita contributed for the schools of Massachusetts, combining the amount contributed by the State and by the town?—A. The grand total for support of schools and buildings is \$13,826,243.41; the local taxation burden is \$13,550,395.78; the whole number of children attending the schools is 474,891; the average membership is 399,423; the average taxation cost of support for each child in the average membership is \$26.06; the average cost of support and buildings for each child in the average membership is \$33.92.

30. "Decline in prices of agricultural products."—A. I do not know that there has been any decline in late years. There is an improvement at present and the outlook is good at the present time.

31. "Decline in money value of agricultural lands."—A. That is treated quite considerably in a little pamphlet which I will leave with you.

Q. (By Mr. A. L. HARRIS.) Do you desire to submit the entire pamphlet?—A. I will quote as follows: "As a farming nation the United States is equalled by none in the amount of her agricultural productions. The farmer has touched nothing but to improve it. The grain is finer, the fruit more luscious, the flower more beautiful than ever before. Under his skillful care he has improved the old, he has created the new, in constantly ascending lines. Each year he is adding to the wealth of the country more, far more, than all other industries combined. The total value of the agricultural production for 1898 was \$4,000,000,000, and the relative value, as seen in the per cent of our exports, has averaged for the last 50 years nearly 80 per cent. Our agricultural export is the measure of our prosperity as a nation. On it rests the great commercial, manufacturing, and transportation interests of the country. It is the golden grain that heaps the nation's treasury with gold. We, therefore, have the right to fair and honorable recognition in all lines of advance. It must be admitted that the farmer is the wealth producer of the nation. It must be admitted that there has been a decline in his relative importance, as also in farm values. In 1850 the farmers owned one-half the wealth of the country; in 1890, one-fourth.

"And the first point is: What is the condition of agriculture in the New England States? Is it prosperous? On this point I shall not deal in theory, but give you facts and figures. The Connecticut labor commissioner made a careful examination of the accounts of 693 farms in 1888, averaging 110 acres each, with the following result:

Value of farms, including buildings	\$3,214,275
Value of farms mortgaged	1,008,350
Amount of mortgages	351,109
Per cent of interest paid	5.66
Value of live stock, utensils, etc	596,467
Total capital employed	3,810,742
Total receipts, including products consumed	707,153

Expense account:

Interest	\$19,673
Insurance and taxes	37,526
Help and their board	157,940
Products consumed in family	126,962
Other expenses	348,889

Total

690,990

Net profits, \$16,163.

"For the condition of agriculture in the fertile farming sections of the country outside of New England, New York gives the latest and most authentic data:

"The New York Society for Improving the Condition of the Poor recently instituted an exhaustive inquiry, at a large cost, into the causes of the depression of the farming interests in New York State. Mr. Kjeigaard, an intelligent Pennsylvania farmer, was employed to travel through such agricultural districts as he could reach during the summer months, in order to gather accurate information by personal inquiry. At the same time Mr. George T. Powell, of Ghent, Columbia County, undertook to pursue the same line of investigation by correspondence. The result is summed up in the statement that farming land had depreciated in value at an average of some 48 per cent; that 30 per cent of the farmers are anxious to leave their farms, and would drift into the city if they only knew how to get work there; that 86 per cent of the farmers report that their children as they grow up can not be influenced to remain on the farms; that tenant farming is on the increase; that 35 per cent of the New York farmers are losing money, 50 per cent dangerously near it, 14 per cent making a profit, and 20 per cent don't know whether they are or not.

"For the condition of the agricultural industry in the Great West, there is hardly a town in New England that has not many reminders of the hard times you have experienced, that have rested upon your farms as a chilling frost, and upon the farm mortgage companies of New England as a nightmare.

"Massachusetts has not been exempt; she can also bring her lesson. By studying the census returns we find the following data:

	1880.	1890.	Decrease.
Number of farms	38,406	34,374	4,032
Number of acres	3,359,079	2,998,282	360,797
Valuation	\$164,288,356	\$146,197,415	\$18,091,941

"These are hard facts and not theories—facts that have had much to do with the welfare of the country, and will have more unless changed, for when the strength of the hills wanes, when the fertile plain is barren, there is sorrow throughout the land, for it lays its benumbing hand on every industry, it stalks through every mart, it carries its chill into the homes of the nation.

"Therefore the prosperity of agriculture is a question for Congress to consider very carefully. It is a question for the statesmen to study—it is the foundation stone of national wealth."

32. "Decline in the productive condition of soil."—A. That is also treated; here is what I say: "Too many of us farmers are mercenaries, not from choice, but driven to it from necessity. The need of the present dollar to support our family, to educate our children, to meet the tax collector is imminent with us. It taxes all our energies to the utmost. The future of the farm must be forgotten, because of the necessity of the present hour. The joy that should spring up to brighten

life, the satisfaction of work well done, the improvement of our farms, the added beauty, the enriched soil are pushed out of sight by the necessity of present needs—demands that must of necessity take from us the joy of life and trail our ideal in the dust; and where is the joy of work, the glory of life, with ideals covered by the hard necessities of unremunerative labor?"

It is a fact that we have been obliged to take from the farm somewhat to meet present necessities, but I think that is past. I think the records of the last 2 years, under the conditions of drought which Massachusetts has suffered, give a wonderful illustration in the prosperity of our farmers of what can be done by intelligent culture and of the strength of our soils. You know we have counties that, in the value of their agricultural products, rank very high. My own county, Worcester, I think, has been third in the value of its products in the whole United States, and Middlesex County was seventh under the last census.

Q. Have you any abandoned farms in Massachusetts?—A. We have partially abandoned farms, but I should say that the State has been doing something toward the repopulation of them with success. We asked an appropriation of the legislature last year to send out invitations for the farmers to send in their list for a new edition of the catalogue. It was partially a failure, and we were very glad to report it so. It shows the improved condition of Massachusetts to-day; there is not a large number of abandoned farms.

Q. Are many of them being reclaimed?—A. They are, yes; and they are being sought for. The conditions of 5 or 10 years ago, it seems to me, are passing away and the outlook is brighter.

Q. Can you speak for any other State except Massachusetts on that important question?—A. It may be New England. It is so thoroughly illustrated by the fate of this publication which we have put out and the returns that came in in comparison with the earlier editions. That of itself seems to demonstrate very plainly that agriculture is improving in Massachusetts to-day.

Q. Are these farms being reclaimed by native Americans or by foreign immigrants?—A. The foreign immigrants, as we would call them, are not coming to them; but the immigrant of years ago who has become a part of our citizenship, is taking them up. On page 33 of this pamphlet, I say: "Inquiries have developed the fact that 159 of the 269 purchasers were residents of Massachusetts, 14 of New York, 10 of Connecticut, 5 of New Hampshire, and the rest scattering or unknown. So far as we can judge 151 were Americans, 14 Irish, 8 Germans, 7 French, 4 Scotch, and the rest unknown. Massachusetts was largely her own purchaser." This was in October, 1899. I say: "Since August 20 last, by actual count, 73 requests for catalogues have been received by mail, and many individual calls have been made at the office. Twenty-nine of these requests were from this State, 17 from New York, 5 each from Connecticut and Pennsylvania, 3 each from New Jersey and Vermont, 2 from Nova Scotia, and 1 each from New Hampshire, Canada, North Carolina, Michigan, Ohio, Texas, Illinois, and Tennessee." It really looks as though those who had gone out from Massachusetts in the years past to the far West were making inquiries as to the conditions in Massachusetts to-day, desiring to return, and frequently they express themselves so to us in writing to our office.

36. "Organizations of agriculturists; causes inducing; objects sought; results secured; rules governing. There are very many organizations, beginning with the board of agriculture, which is followed by the agricultural societies represented on the board, and then by horticultural societies, farmers' clubs, and Pomona and subordinate granges. There are in the State 34 agricultural societies represented on the board of agriculture, 9 horticultural societies, 16 farmers' and mechanics' clubs and associations, 24 farmers' clubs, 16 Pomona and 158 subordinate granges as well as the State grange, and 18 agricultural organizations of a miscellaneous nature. In our annual report is a complete list of them with their officers and location.

I think the improvement in agriculture has very largely come through these organizations. They meet together and discuss methods of farming until the old methods have disappeared and we are adopting better ones. Our institute lecturers comprise as fine a class of our college professors and practical agriculturists as can be found in the New England States. I am sorry that I have not with me a copy of our list of institute speakers and their subjects which is sent to every agricultural society; and their institute committee, or the member of the board of agriculture representing that society, selects the speaker best suited to their needs and conditions. They then send to us asking that such a speaker on such a subject be furnished them. We at once make arrangements and he is sent to them. We take up subjects on every line, not simply on fertilizers, and soils, and crops, but improved conditions in the house and farm, household conditions,

etc. We have one or two ladies among our lecturers and I hope we will have more.

Q. Do you have assistants from the locality—local talent?—A. Always. We furnish one institute speaker who is paid for by the State—his expenses and so much per lecture; anyone on this list. The people usually meet in the morning and have a topic discussed by local agriculturists, or they may select a local lecturer, if they please, and pay him. Then follows the speaker we furnish them in the afternoon. We desire the local people to take part in the discussion at every institute, as only in that way do we get the most interest and the best results.

Q. Who makes up the programme?—A. Aside from the lecture it is made up by the agricultural society, according to the needs of the towns. It induces a local interest which gives us a large attendance. Last winter was an exceptional one on account of storms, yet our institute attendance averaged 91, in spite of storms and other incidents that came in to lower the percentage in certain localities. This winter, I think, we shall go beyond that average. Never before have we had such a demand for lecturers. We are carried beyond our means, and the appropriation of the State is supplying them. Another pleasant feature is that the report of the board of agriculture, coming out a year ago, has been entirely distributed, so that we are now obliged to send to the local agricultural societies to see if they have any remaining not distributed, and asking them in that case to let us have them to fill present calls. We find that we are receiving but very few from this source. By and by some will come back to us, because each member of the legislature has so many copies, and some of the legislators in the cities do not care for them, and the 1st of April they will be turned over to us to supply the deficiency. It was something never known before, that the visible supply of the report of the board of agriculture was exhausted within the first year after its issue. Our annual edition is 15,000 volumes.

Q. Do you hold more than 1 institute in a county in a year?—A. Yes; we have, as I have said, 34 agricultural societies. Each 1 of these societies, in order to receive the \$600 bounty from the State is obliged to hold 3 institutes. Add to that number those we furnish to the granges in sections where there is no agricultural society covering the territory, and you will see that every section of the State is supplied with institute speakers, and as we have only 14 counties in the State we usually have 8 institutes, at least, to a county. That is, on an average, the meetings being distributed by area rather than by counties, and the larger counties getting more of them than the smaller ones. We furnish the granges and farmers' clubs with speakers so far as we can, but the call is greater than we can supply at the present time under the appropriation for carrying on this work, and we are obliged to disappoint many of them.

Q. Nothing has been said, I believe, about your experiment station. We would like to have the work that your experiment station is doing for the farmer explained.—A. I am not prepared to speak on that work as I would desire. I wish you could have President Goodell, of the agricultural college, to tell you of the work there, because they are doing a very fine work. All the experiment stations are doing fine work in the New England States.

Q. I do not care about going into the particulars, but I would like you to give us your judgment as to the advisability of continuing the agricultural experiment stations.—A. I think they have done a very, very great deal for agriculture in New England. It was our experiment station which first led us to see the way in which the farmers were being cheated in fertilizers, and under the lead of Dr. Goessmann we secured the law on that subject, which was the first of its kind, and which has been followed by nearly every State in the Union. Of course the experiment station was started as an experiment. It had to strike out lines for itself. It was a new thing. Everyone was calling for experiments in his particular line. It could not take up all the lines, but, choosing those that seemed to its management most pressing, they have worked along those lines until they have obtained exceedingly good results. Before the establishment of these experiment stations experiments by private individuals were often widely advertised as demonstrating some particular truth, and were afterwards found to be simply the result of 3 or 4 years of continued peculiar conditions, and the experiments were valueless for that reason. Our experiment stations are not working in that way; they are taking no chances, but are making such conditions that the experiment when tested and proved is beyond cavil, and the result is assured. Thus our experiment station is at work, as it has been, in the testing of fertilizers, the germinating power of seeds, the application of fertilizers to plant growth, the relative value and productiveness of grasses and forage crops, insecticides and spraying and diseases of trees and plants, the sterilizing of soils to promote plant growth, stock feeding and determining relative quality, productiveness and value of grasses, fruits, and vegetables for markets. These are some of the ques-

tions there demonstrated. Having been educated by the institutes and by the necessities of the case, our farmers are buying the elements of plant food very carefully. They are not wasting money on fertilizers, but are buying the proper ingredients needed by the soil and crop they desire to produce. All this has been brought about by the experiment station, the institute, the meetings of the granges, and our farmers' clubs working together as a band of brothers.

Q. Is your institute connected with the agricultural college?—A. There is no connection, but all the professors are on the list of institute speakers.

Q. I had in mind your experiment station. Is your experiment station connected with the agricultural and mechanical college?—A. It is, and yet it is not. They are working in harmony.

Q. Have you any other organizations except those you speak of?—A. We have the grange, of which I have not particularly spoken. It is doing an excellent work and working in perfect harmony with our board. It has done a great deal to uplift the home and to add to the attractiveness of farm life. As I say, I was State lecturer for 6 years, and was all over the State and met the farmers in their homes and in their meetings. There has been a wonderful improvement, quite largely through the influence of the grange. It has added beauty to the farmer's home, as well as intelligence and attractiveness to the home life, because it incites pride in the surroundings and content on the whole.

Q. Have you an organization of farmers' clubs?—A. We have farmers' clubs, but no organization of them. The grange has very largely taken the place of them. Some still remain. We meet them just as we do the grange, and supply them institutes where we can. Organizations of agriculturists in the State are as follows:

Agricultural societies	34
Horticultural societies	16
Farmers' and mechanics' associations and clubs	47
Pomona granges	15
Subordinate granges	159
Lectures given under the auspices of the board of agriculture	135
Average attendance at these lectures	91

The objects sought are educational and social. The lecturers for our institutes are the best talent we can obtain, securing practical men on each subject from the colleges and experiment station forces, or our most successful and progressive agriculturists on their best considered specialties.

Q. What have you to say in regard to the diversification of agriculture in Massachusetts?—A. I should say it is very diversified, but still in the line of the home market. The market garden, truck farming, and selling truck direct from producer to consumer in our larger villages as well as the large cities lead to a very diversified line of farming. The old lines are followed largely in some parts of the State, as in the Berkshire Hills, where they have no such market. The prosperous farmer is the one that has some specialty—not entirely working on a specialty, but has some one thing in which he is trying to meet present demands and the present market. We are not, as farmers, working for the foreign market. We are glad if it is good because it helps our own market by raising our prices; but the productions are largely for the home market.

Q. Have you much dairy farming?—A. Yes; milk and creameries. The milk supply for our cities is a large item in our farming life.

Q. Is that profitable?—A. Yes, to a certain extent it is profitable. The milk farming is of course for the large cities. I think it is profitable in all sections except in those which supply the Boston market; and I suppose it must also be profitable there or the farmers would not continue it, although matters in this market are not satisfactory. But around our smaller cities milk farming is profitable, and the making of butter among our country towns is quite so, because they have their special lines and special trade, and they receive remunerative prices—prices higher than the market because they are making a good article of uniform character and quality.

40. "Effect of improved agricultural machinery." That is an important factor with us. Of course it does away with a great deal of labor and enables us to produce larger crops at a smaller cost, so it gives us a margin of profit which we could not have but for the improved machinery. We could not to-day go back to the old methods and supply the New England market.

Q. Have you much fruit farming in your State?—A. Yes, we have fruit farming. Apples are raised to a large extent and are profitable, I think. Our apples are of a good quality and they find a foreign market. That is one of the things we ship very largely.

Q. (By Mr. LITCHMAN.) Can you name the varieties of apples?—A. The main apple for shipping purposes is the Baldwin, but we have the Ben Davis, the Gravenstein, the Greening, the Roxbury Russet. The Sutton Beauty is another variety, originating in my town, that is now taking the lead for quality and market properties for the home market or for shipping. The list includes all our best varieties of apples.

Q. The Baldwin is a very hardy fruit, is it not?—A. It has been so. The foreign market demands a red apple, and the Baldwin is red; and while its quality is not up to some varieties it is a good shipping apple. It is attractive and they appreciate it. It has been the apple of New England.

Q. In how high a latitude can it be cultivated?—A. It is raised in Canada.

Q. How high up?—A. I can not say. Canadian apples stand high in the foreign market. The northern apple keeps better than the southern. I suppose our apples keep better than those grown in Pennsylvania. We are raising peaches again in Massachusetts. How successful the crop may be I do not know; but there is quite an experiment in that line and profitable so far, I think.

Q. Peaches used to be generally cultivated in Massachusetts, did they not?—A. Yes.

Q. Have you any reason for their going out?—A. Conditions of soil, lack of certain elements, insect enemies, and other reasons hard to understand. Even now we think if a peach tree lives its 7 years and we get 2 or 3 crops it is profitable, and we are ready to throw it away. As a boy, I used to pick peaches up under the trees as we now pick up apples.

Q. (By A. L. HARRIS.) What is the character of your roads and highways?—A. I think, in comparison with other States, good.

Q. Is the interest in their improvement increasing?—A. Well, we have the highway commission, and we have the law under which they furnish a road to a town free, or very largely free, as an incentive to the town to have good roads. In our country towns there is so good a piece of road that the country can hardly imitate it, but it is having a good effect and is increasing the number of good roads. We realize that in Massachusetts, as I suppose in all other States, the roads are an index of the character of the people; that the civilization of the people is shown by the roads. We think our roads and roadsides are growing increasingly comfortable and attractive to the traveler, and the roadside increasingly beautiful. Not only our board of agriculture takes an interest in this, but we have a forestry association which is looking to this point also, and in all these points we work in harmony.

Q. Does your State aid in the building of roads?—A. It builds roads. As I indicated, it has not done much so far in continuous lines, but a mile here and a mile there, but the plan is to eventually bring these lines into continuous communication so they will be of great value to the traveling public.

Q. (By Mr. CLARKE.) What have been the appropriations of the State for State roads since the policy of building State roads was entered upon?—A. \$3,021,867.76, including cost of bridges and culverts.

Q. (By Mr. LITCHMAN.) Will that policy eventually result in State roads from the eastern to the western boundary of the State?—A. That is the plan as now being carried out.

Q. (By Mr. A. L. HARRIS.) I have seen in the paper something about the great milk combine.—A. Oh! in Boston; I think one of the milk producers could give you light on that subject. Mr. Ward, of the Milk Producers' Union, would, I doubt not, be very glad to come before you.

Q. You are not conversant with it?—A. I am not a milk producer.

Q. Such a thing as the combine exists?—A. Oh, yes, indeed; and it needs a remedy.

Q. Can you say whether such a thing is looked upon as a benefit to the producers or not?—A. The action of the producers at their last meeting would not indicate that it is. Nevertheless, they can not get along without some combination to dispose of their milk and they must go outside of the producers and the railroads.

Q. Is it generally supposed to be satisfactory?—A. It is not satisfactory. It has caused a great deal of dissatisfaction, and I do not know how it will result. There is an undetermined factor called "surplus" that causes a great deal of dissatisfaction and friction. It has caused the present strike, if you call it that, of the Milk Producers' Union, and both parties are, I think, anxious for a settlement.

But, returning to my statement, when it comes to the Federal and State laws touching agricultural industry, when we speak of taxation and its effect upon the farmer, we need ourselves to take into account that the increased cost above what is actually necessary in any line is unjust, and, to that extent, a tax; and when we consider the question of trusts, as they are now, I conceive them to be an evil.

while they might be a great benefit. But it would seem to me, with our great combinations and giant monopolies, national legislation should step in and say that they are not infant industries to be protected, and leave them outside and give the consumer the benefit of the world's market, at any rate.

Q. Have you a remedy to suggest?—A. In every case of a large combination or trust the world's market should be opened to this country. Protection is a misnomer and a fraud under these circumstances. Infant industries and giant monopolies are not synonymous. To-day the people are more than the industry. The man is better than the product, and it is the man that needs protection.

Q. (By Mr. CLARKE.) Representatives of 6 independent tin-plate plants in this country, those entirely outside of the trust, have testified that if tin plate were put on the free list that action would ruin their industries and would not essentially harm the trust; therefore it would destroy competition in America, and, in their opinion, would result in an international combine, so that prices would be higher to the consumer than now. Can you conceive that it might work that way?—A. Yes; the Standard Oil Company is international, I believe, and protected; but I do not think that is an answer to the question, because you take very many other giant monopolies and if there were some way by which the consumer obtained a fair equivalent, instead of an immense preponderance to the monopolies, it would be a great benefit. There are exceptions to every rule. In the case of the tin plate suggested, while the country is helping by its protective tariff, to a limited extent, these 6 plants, it is also putting immense profits into the hands of this trust octopus by which it can, at an opportune moment, destroy the weak industries named, or bring them into perfect accord with the trust; or, perhaps, they are allowed to live for the influence they have in sustaining this very tariff. One thing seems to me sure, this immense revenue to the rich by oppression of the poor can not continue in this country. The man is more than the product; the people more than the trusts. The enormous aggregations of capital and the unequal division of wealth are the menace to our institutions to-day. Besides, it seems to me suicidal. These taxes and exorbitant prices may enrich the few, but they are taking bread from the laborer and clothing from his family by curtailing his power to buy, and thereby the mills are rendered idle and the product unsold. The farmer is the loser. As I have before said, a prosperous, intelligent, and contented people are the wealth of a country and the home market of its products. We farmers realize this when we take a load of truck to a manufacturing village. The intelligent laborer, standing for his right, is the safest trust in this country to-day.

Q. Have you any way to suggest of controlling the trusts?—A. No; not at all. Only with a great many of these combinations I should throw open as far as may be the markets of the world, and reach others by taxation and severe laws against combinations endeavoring to control trade.

Q. Would not that destroy domestic competition with them?—A. I think not. The trusts have destroyed that already.

Q. Is it not the small concerns that need the protection rather than the large?—A. There are very few small concerns in such an industry as the oil industry for instance. The combination has killed them out. The book *Wealth Against Commonwealth* gives the method and the results.

Q. Are you not aware that there is a very large oil company in the country with millions of capital involved which competes with the Standard Oil Company?—A. It is trying to do so, but it will eventually be dissolved, or else it will work into perfect harmony with the Standard Oil Company, as the so-called competing sugar refining companies are with the American Sugar Refining Company.

Q. Is it not the rule with our industries that when one becomes very profitable capital rushes in and competes with it?—A. Yes; if it sees safety and profit in the contest rather than in consolidation or combination.

Q. Do you not think that if the protective policy is maintained capital will still be induced to compete with any concern which is formed by the combination of others?—A. The results of the sugar contest between the American Sugar Company and the Spreckels interests, and the coffee war between Havemeyer and the Arbuckles are not encouraging symptoms in regard to such matters, and the fate of the smaller producers in their contest with the Standard Oil Company, as set forth in *Wealth Against Commonwealth*, are not likely to encourage small capital in entering on contests with large combinations. In the battle of the giants the people have gained nothing. In the case of the telephone it so happens that I was in the legislature at the time the first charter was given out. I was chairman of the committee, and was therefore somewhat familiar with those who were engaged in it. Some 20 years later I went to the telephone office to inquire as to the probability of its continuing to be a profitable investment—not that I had a dollar in

it, but for another party. They informed me that they were covering the ground so perfectly or were endeavoring to do so that there should be no opportunity for another company or another corporation, thereby holding their grip upon the situation, which was wise in them. It was good business policy, but it would seem to me that after the Government had protected them, given them all the benefit which accrued to them from the patents, that it should not continue to protect the monopoly so that it should receive more than a fair profit. The rest should be the people's.

Q. How does the Government protect the monopoly?—A. By the charter granted by the State, under which the stock to the amount of about \$50 millions is exempted from taxation, while the company protects its monopoly by covering the ground so that nobody else can get a foothold.

Q. Is it not a fact that there are competing companies?—A. It is very hard work for them to get a foothold.

Q. Why?—A. Because the ground is so well covered now that competing companies can not offer sufficient inducements so that cities will allow their streets to be taken up with a double line of appliances.

Q. Is it not a fact that a competing company has been laying wires in Boston within the last year?—A. Yes; they attempted to get the same right in Worcester, but I think the conditions were so hard that they had to give it up. I did not wish to speak upon this matter, because it is outside of my line, but I think it the duty of the State or nation to cease to protect any corporations which are receiving an undue proportion of the profit of that protection and are not sharing it with the people.

Q. There are people who claim that when an industry is able to export part of its product it ceases to need protection and that the tariff is inoperative. If that is so, would the repeal of the tariff do any harm to that corporation?—A. My impression is that in certain lines there are industries that are exporting their products and selling them at a less price than at home. In such cases the tariff should be taken off, and if exemption from taxation has been obtained it should be revoked.

Q. Are you not aware that that is the practice of all exporting countries, irrespective of their tariff conditions?—A. Perhaps so, but does that make it right, or politic even?

Q. When remedies are recommended we wish to find out whether they are remedies or not?—A. I believe that is for you to judge.

Q. If you have any information on that point, as to the practical working of it, we would like to receive it.—A. In the first place, I would reach them by taxation. These corporations that will bring a return of 12, 20, and 40 per cent ought to be taxed "according to ability." That is our good phrase in Massachusetts, and it is perfectly legitimate to let their returns be open and known to the Government that protects them and gives them their opportunity.

Q. Would you reach them by local taxation under State laws or by Federal taxation under the internal-revenue system?—A. I do not know how you would reach them. That is for the lawmakers to decide. I will do all I can to see that Massachusetts shall reach them.

Q. You mean to say that so far as it can be done within constitutional limits you would do it by State or by national laws?—A. Yes; and if you break over and throw aside the Constitution for any purpose, it should be for this rather than for any other. There is no greater crime in Massachusetts than the double taxation of the poor and the exemption of the rich—indirect taxes levied by tariff duties and trust monopolies and direct taxes caused by the exemption of 15 millions of wealth in this State. No truer words were ever spoken than those used in the declaration of ex-President Harrison in his address on "The obligations of wealth," when he said: "Equality is the golden thread that runs through all the fabric of our civil institutions. We must inaugurate and at once a system that will equalize tax burdens. Mr. Lincoln's startling declaration that this country could not continue to exist half slave and half free may be paraphrased to-day by saying that this country can not continue to exist half taxed and half free. If we admit the disgraceful conclusion that the state of public and private morals is such in our country that the wealthy may not be brought under the law and compelled to yield it reverence and obedience, have we not confessed the failure of republican institutions?"

President McKinley has said: "Equality in taxation should be had. Real estate and other tangible property now pay the large share of the taxes, while other varieties of property, which are not tangible, either wholly escape or bear a disproportionate share. One class of property should not be exempt at the expense of another."

Q. Is there any sheep husbandry in Massachusetts?—A. Very little at present.
 Q. Why are there not more sheep in the western part of the State?—A. There are more there than elsewhere, and I hope that sheep raising is coming back to Massachusetts. We, as a board, are doing what we may now to encourage the return of the sheep to the State, but the industry has not been a profitable one. In my boyhood days sheep were on every farm and were considered a necessary part of the farmer's outfit.

Q. Is the absence of an effective dog law in the State a reason for the farmers not going into sheep husbandry more?—A. It is, very largely. I do not know if we had the sheep we used to have but that the dogs might get used to them and not worry and destroy them, but at present there is no effectual barrier against dogs by our laws. Going into sheep husbandry includes wire fencing and the necessary protection from dogs by careful work and constant watchfulness.

Q. Is it not a fact that every time farmers appear before the general court and ask for an effective dog law it is strongly opposed by the owners of dogs in cities and towns?—A. Certainly it is. Some of the hardest fought hearings that we have and the most largely attended and most violent, if I may use that expression, are when the farmers appear there and ask that their sheep shall be protected. Any slight suggestion that we make with reference to the owner having the dog on his own premises or caring for him personally, so as to get rid of tramp dogs, is badly received. The dog in Massachusetts is supreme. Even the society with the long name never considers the sheep as against the dog.

Q. Is it your opinion that if sheep could be adequately protected from dogs in Massachusetts the industry would grow here and be a source of revenue amounting to millions of dollars a year to the farmers?—A. I think it would. It would be a great help if we could have the sheep industry. But I have been in the country towns and I have seen too much of the injury to flocks of sheep from dogs to advocate sheep husbandry very strongly under present conditions. The State protects the farmer to a certain extent by paying him for a sheep that is destroyed; but that is no protection, because when one sheep is destroyed the whole flock is demoralized, and the owner never knows the amount of damage to the flock within perhaps a year after. The after effect of fright upon sheep is something wonderful. I went to one farmer's house where his sheep had been mutilated by dogs and I saw them in different conditions. It was enough to make anyone sick. Sheep were trailing their entrails upon the ground and still alive when I got there. They were otherwise mutilated as dogs do mutilate sheep. I paid the farmer, or asked that he be paid liberally, and the award went to the county commissioners and was paid. Six months later he asked me if I would come to his place. I went over there and saw his flock of sheep, and he had not been half remunerated for the loss. The number of sheep that had produced no young and the quality of the young showed the after effect of the fright on the flock. One peculiar instance was a lamb that had very nearly the appearance and the bark of a dog, caused by the shock of that fright. And there was no remedy whatever; the farmer had to suffer the loss. There are no sheep upon that farm now. They continued the business years after, but the dogs so frequently worried them that he let it pass and gave up the husbandry.

Q. Is there a considerable tobacco industry in Massachusetts?—A. Yes; in the Connecticut Valley and to a limited extent in the Housatonic Valley.

Q. Is it in a thriving condition at the present time?—A. It has been for the last 3 years.

Q. Was it depressed from 1894 to 1897?—A. I can not tell you the exact years of this depression, but it was very much depressed, so that there was no sale for it, and the farmers were in bad lines because of having their crops on hand and the cost of production, which was great.

Q. What was the cause of the depression?—A. No sales, because of fear of tariff changes.

Q. Are you able to state the cause of the present prosperity?—A. In both cases it was the favorable season and remunerative price, of course; but you mean the ulterior or previous cause.

Q. I mean the cause that affected the price.—A. I can not go into that. It was not the actual tariff, as the changes have been slight under the McKinley, Wilson, and Dingley tariff acts.

Q. (By Mr. LITCHMAN.) You intimated your opinion as being in favor of action by the nation to reach these monopolies. Do you mean by that the removal of the tariff?—A. It seems to me that the idea of the tariff was for the advantage of infant industries. That was the original idea, and it is the right idea, it seems to me. And when the infant industry becomes a giant monopoly, holding the whole nation in its grasp, it is time that it should receive no help in so holding it, at any rate. The people should be protected, not the industry.

Q. Those industries, to get into the markets of the world, must necessarily compete with manufacturers and countries where there is no tariff?—A. Certainly.

Q. Will not competition, then, come purely on the price paid for labor in the respective countries?—A. I do not think so. Labor will protect itself.

Q. It has been testified repeatedly before this commission that the labor in this country is compensated from 50—I think in one extreme instance to 500 per cent higher than similar labor in foreign countries. Now, in this country if the doors were thrown open to labor receiving only 50 per cent of the wages of the labor of this country, would it not compel the scaling down of the wages of the labor of this country?—A. Labor depends upon several conditions. Where you find labor lower in the old country you find it because of the conditions by which it is surrounded, to a certain extent. For instance, the house is cheaper; everything that labor lives upon is cheaper. They have a lower scale of living, to be sure; but it seems to me that we have no fear of that when our corporations send abroad and compete with this labor on its own shores at less prices and hold us to the high prices.

Q. That is the assertion, but as yet no evidence of that fact has been brought before this commission. But assuming that that is the case, may it not be a similar condition of affairs to that under which, as testimony before this commission shows, foreign manufacturers have dumped the surplus products of their mills and factories on the United States at a price less than the same goods were sold at the same time in foreign countries, like causes producing like effects? It has also been testified before this commission that it is more profitable for a factory to run its production at the full limit and extent of machinery employed, even if a portion of the product should be sold in foreign markets at a little less price. In the general average of production, do you think that may be a fact?—A. I think it probably is a fact, and that is what I object to—that the farmer or consumer in this country is at the wrong end of the average.

Q. And may explain why, under certain circumstances, products have been sold at a less price in foreign markets?—A. That would be, in part; but if it were not for the percentage which they are getting over and above the actual value of money they would not continue to manufacture and extend their manufacturing here, holding these prices so high.

Q. It has been testified repeatedly also that during the last 3 or 4 years—during the present period of so-called prosperity—that the price of the finished article has been constantly decreasing, while the price of labor has been constantly advancing.—A. But you have machinery which is making that possible and still giving better returns. It is conditions which are making that possible and still giving better returns to the investor.

Q. But how can you escape the competition of foreign-made goods, if there is open access to this market, except by a reduction of the wages paid to labor in this country?—A. By a reduction in the returns to the manufacturer himself or to the trust or combination that is receiving it unduly.

Q. Is it not true that the higher the type of the product the greater the skill of the labor employed in it, as a rule?—A. In certain lines. The intelligence of machinery is to-day the most wonderful thing in the world.

Q. How can you prevent such a monopoly from operating when there are no duties on the product to be repealed?—A. I am only suggesting one simple case of the giant monopolies, and I say that if there is any way in which they can be reached, I think taxation according to their ability would certainly have an effect upon them. This would not lower the price to the consumer, but it would lessen the burden of taxation.

Q. I understood your intimation to be that you would take off the tariff on those industries?—A. Certainly, where the tariff would affect them, but in every case I would make taxation according to ability. For instance, right here in our State of Massachusetts, and I suppose it is so in other States, there are in the cities our rich men who are paying taxes on half that they possess, and perhaps less. They are building beautiful halls and libraries and things of that kind, and their names go down to posterity as being benefactors to their cities and their race. Instead of that, they have cheated their cities and towns out of taxes, and put upon others the taxes which they themselves should have paid.

Q. What is your opinion of the income tax?—A. I think it is a just tax.

Q. Do you not think it would be a good thing to have an income tax?—A. I do not think it is sufficient. I think we should have the taxes upon property. If a man will lie, that is the end of it; but we certainly should do what we can to bring about equal taxation, and honest returns should be enforced. It is the Government's right and the State's duty to enforce the law, and there is no hardship in its enforcement. The hardship is in the cheat, and the danger in the lack of moral honesty and the sentiment that the country will go to the dogs if idle capital pays

its equal share, forgetting that stocks and bonds or idle capital is of small advantage to any State compared with its productive industries, the true wealth of State or nation.

Q. That is the remedy that you would suggest as a matter of State legislation?—A. State legislation.

Q. There is an income tax in Massachusetts, is there not?—A. Yes; for over \$2,000.

Q. I understand your idea is that you would force each man to declare his property under oath?—A. Yes; the Government has a right to do that.

Q. Have you in Massachusetts a law that has substantially that provision now, but which gives the assessors power to assess according to their will and opinion if that declaration is not made?—A. We have, but our assessors are under the control of the towns, and that law has been set aside. It is legal advice rather than law, because there are no penalties attached. Doomage under our present law is a cheap expedient for the tax dodger, and multitudes avail themselves of it here in Boston, and in our other cities and towns, and some few build libraries, art schools, etc., posing as public benefactors on the money stolen from the State's dues, while the great majority simply cheat the State and glory in their work.

Q. You would, then, have the law so fixed that there would be no possible evasion of the sworn declaration by every taxpayer?—A. Yes.

Q. (By Mr. A. L. HARRIS.) You spoke a moment ago of the farmer being prosperous at the present time in Massachusetts. Has that condition obtained for many years past?—A. It has not. It is coming to us now.

Q. How long was it that the agriculturist was in a bad condition financially?—A. Four or 5 years, I think. The improvement is marked at the present time; there is a brighter outlook.

Q. How do you account for the change?—A. The prices and conditions are better. The farmer's improvement is different from what it was. His opportunities are different from what they were; prices are better; he has turned his attention from the old lines to the new, and he has got into the new lines, so that he is receiving the benefit.

Q. Do you think of any law, either Federal or State, that has had any effect upon the present prosperity of the farmer?—A. I do not think that any have had. I think these were natural conditions. Massachusetts and the adjoining States were at the lowest point; land was so cheap that it was being bought for investment. People saw that it was a condition that could not continue, under the circumstances, and there has been in very many of our towns land bought simply for investment. I met a gentleman in Boston Saturday afternoon walking on the street who had bought land in Vermont lately at an auction sale simply for investment. So people realized that it was at the lowest point, and therefore they are looking for brighter times. Then we see, in connection with our abandoned farm work, that there is more desire to retain the farms. Practically, there are no abandoned farms in Massachusetts to-day.

Q. Does the farmer get any advantage from protective legislation—not directly, but indirectly?—A. I would not care to answer that question. That is a subject that I have not studied, but I should say that protective legislation is rather to the injury of the farmer, increasing the prices of what he has to buy and of labor. This more than offsets the advantages he receives from a better home market. He has no part in protective legislation to-day under present conditions to which I have alluded. Overproduction of wheat and corn in the West, and lack of a European market, the ranches on the plains, and the beef combine left New England no profit on the farm in the old lines of farm work. Now the progressive farmer is working on new lines, which are more profitable and with a brighter outlook.

Q. Does the farmer reap any advantage from the general prosperity of the country?—A. Oh, certainly. He is reaping it now to quite an extent.

Q. Can you account for the present prosperity of the country?—A. I do not think it is entirely due to the protective tariff; neither do I think the present prosperity, so called, is entirely healthful. The Government is the large factor, the large purchaser; and the farmer, if unduly taxed, must pay an undue price for the seeming prosperity, which must be transient, and the people must pay for what the people's Government has bought. We forget the settlement day, which must come as a natural sequence. War is a tax always and ever, and is only to be justified by dire necessity in this age of the world.

Q. Has the protective tariff had any effect?—A. I have no doubt it has to a certain extent on the present condition of the country. The farmers of New England gain somewhat from the protection given from the agricultural products imported from Canada and the Provinces, particularly hay and potatoes, and also from the tobacco tariff to which I have referred. There are several advantages, but, taken

all in all, to-day under present conditions it is a serious question with me whether there must not be a change. The farmers have been, and are now generally for the protective tariff for the benefit of the people, but not to build up trusts and combinations of capital that are unjust and oppressive, whether it be to lower the price of the raw material or increase the price of the finished product by absolute control. You understand, I do not oppose the protective tariff for the benefit of the people only when such effect is nullified by the power of combination. How this is to be remedied I do not know, but I am convinced that it must be remedied, for this is going to continue to be a government of the people, for the people, and by the people.

Q. Is not the indirect effect very important to the farmer?—A. Certainly; the farmers are generally for the protective tariff to encourage industries, but not to build up giant monopolies that are oppressive.

Q. That is as far as you go, but would you be able to draw the line or stop at that point?—A. I think so.

Q. Have you a pure-food law in Massachusetts?—A. Yes; we have pure-food laws in Massachusetts, and a State board of health with money to enforce the laws. We have a dairy bureau and an oleomargarine law to punish fraud in food products which has stood the test of the highest courts, and is being largely copied in other States.

Q. Your laws are satisfactory, so far as you know?—A. I think so, and are working well.

Q. Have you any suggestions as to additional legislation upon either oleomargarine or pure food?—A. We have done what we could to encourage the Grout bill in the Congress of the United States, feeling that oleomargarine is a fraud upon the dairy interests of the country that should be abated, and that the manufacturer of oleo should take some other color at any rate by which to distinguish this product so that it might be sold upon its own merits, simply acting against it as a fraud.

Q. Can you give the commission any information as to Federal legislation upon the subject of pure food?—A. I can not at this moment.

Q. Do you think it is important?—A. I do. We have, as I say, urged the Grout bill, which is now before the Senate.

Q. I have in my mind something after the Brosius bill. The pure-food bill and the oleomargarine bill are different.—A. The Brosius bill we are in favor of.

Q. Would you lodge the execution of the law in the Agricultural Department at Washington?—A. Anywhere that it would be most effective.

Q. I wish you would state whether your laws to prevent the spread of infectious diseases among animals and plants are sufficient?—A. We do not think so.

Q. Have you any suggestions to make for their amendment?—A. The board of agriculture had thrown upon it a few years ago the work of suppressing the gipsy moth, which is a pest which was brought here from a foreign country by a professor in Medford, producing a caterpillar which eats every green thing, multiplying in large numbers. When it became thoroughly unbearable there they came to the legislature of Massachusetts, and later a commission was appointed. That commission not working satisfactorily, it was thrown upon the board of agriculture, and the board had the care of it and spent a million dollars towards its extermination. Last year the legislature seemed to have gotten tired of the work, and no appropriation was made. I presume none will be this year, and the moths will therefore be allowed to spread. It seems to me that when that covers our country it will be the greatest pest ever introduced or brought here. I do not see any stopping of its ravages unless we find some aid from nature or from parasites. Our climate seems to agree with it. It does more damage by far than in its old haunts in the Old World.

Q. To what extent was your effort successful?—A. It was such that there was an investigating committee last winter with reference to the subject, and the investigating committee at the close of the investigation said that there was not now a single large colony extant. We felt we had it under control and that in a few years more we would have entirely wiped it out of the State and thus out of the country.

Q. Have you made any effort to have the Federal Government take up the subject?—A. There has been an effort made by Congressman Thayer, and there was a committee appointed who appeared before the General Government at Washington 4 years ago, I think; and now that Massachusetts has given up the work it must be national, of course; in order to stop it.

Q. Can you recommend some legislation along that line by the Federal Government, not only to include the gipsy moth, but also other insects?—A. The gipsy moth is a peculiarly dangerous insect, and also an insect which can, if attacked at once, be exterminated. The female moth never flies. It never moves far from

the place where it emerges. It remains right there, or near there, lays 600 eggs upon an average, and then drops to the ground dead. It therefore does not spread rapidly, but only as the caterpillars crawl, seeking food. We have the brown-tail moth here, and it is doing a great deal of damage, but in that case the female flies over the country and we can not control it. The expenditure of money would simply lessen its ravages, but it can not be exterminated. The gypsy moth can be exterminated now before it has made greater headway. Therefore it is peculiarly a matter that the National or the State government should take hold of. The State government has done so, and the National Government ought to take hold, and the work ought to be continued. But I have no hope now that it will do so until after the moth has spread or been carried so broadly over Essex and Middlesex counties that it can not be exterminated. But it must be suppressed, and the State will, I believe, spend four times more money in the next 15 years in suppression than it would have cost to accomplish extermination, and then at the end of 15 years the cost to individuals, the State, and the nation will have only begun. Yet the leaders in State legislation believed it a fad and a scare, though every reputable entomologist in the nation, including Professor Howard, of the United States Department of Agriculture, urged forward the work.

Q. (By Mr. LITCHMAN.) How much has the State expended? Do you recall?—A. \$1,100,000.

Q. (By Mr. CLARKE.) The brown-tail moth is also a recent importation, is it not?—A. Yes.

Q. How large an area is infested by that moth now?—A. To speak generally, quite considerable of the eastern part of Massachusetts.

Q. And that has occurred within what time?—A. Largely within 6 years. There is a very strong effort being made now by Cambridge and the cities and towns around here to get rid of that for the coming year by destroying the nests.

Q. Do you think that it has got beyond control now?—A. I think it has got beyond extermination. It began in a very small territory. Then was the proper time for extermination; but the next year the circle was much larger. In spite of anything that the board could do we found it constantly spreading, and with the female flying as far as it could, its extermination soon became impossible. The nest is easily seen and can be destroyed in the early spring; after that spraying is all that can be done, and that is hardly effective. But the gypsy moth should be exterminated for the benefit of the whole country. It has been the fear, I think, with the National Government that if it took hold to exterminate one insect pest there are so many of them which it would be called upon to exterminate or suppress that it would be impracticable, and therefore they were afraid to take hold of the one which was a necessity, for fear it would lead to other expenditures which would not be wise because they could not be controlled.

Q. (By Mr. LITCHMAN.) There has been no other insect found that would prey upon and destroy the gypsy moth as yet?—A. Not yet; there are many birds and there are some insects that do prey upon the gypsy moth, but not to any extent. We have tried to discover insect parasites, but have found none which did any appreciable amount of good. I understand Secretary Wilson has imported from Europe two insects or parasites, and the result of bringing them may be like that of the scientist over in Medford. He brought the gypsy moth here to improve on the silkworm, if possible. Professor Shaler, of Harvard, told him the danger and Mr. Trouvelot attempted to destroy them, realizing the danger; but unfortunately some had escaped him, and a few years later the people of Medford were at the statehouse saying that their houses and walks were covered with caterpillars and life was unbearable because of them. It was an accident for which they are very sorry.

Q. (By Mr. CLARKE.) Did not the fight of the State against the gypsy moth succeed in circumscribing it about 75 per cent?—A. Yes; more than that. As I said, the investigating committee were obliged to say in their report that there was not a single large colony extant to-day. We had so nearly exterminated the moth and had it so well under control that watching and care for a few years longer was all that was necessary, and we were looking forward to its entire eradication with perfect certainty.

Q. Is any bill pending in the present general court for a new appropriation to continue the work?—A. I think not. The report of the State board of agriculture upon the matter is before the general court, and I think that one senator has a bill before the general court with reference to doing away with the law which places the pest under care of the board of agriculture.

Q. (By Mr. A. L. HARRIS.) Is your law to prevent the spread of disease among domestic animals sufficient?—A. It is certainly holding disease in check. We have our cattle commission, and the appropriation under its control is holding contagious diseases in check and preventing their influx into Massachusetts.

The natural increase of disease I do not think is fully covered by the law, for the appropriation is not sufficient to wipe out tuberculosis.

Q. Who executes that law?—A. The cattle commission, a commission of 8 members.

Q. Is it authorized to destroy infected herds?—A. No, it is not. It is authorized to destroy certain infected cattle in a herd, but it does not go to the extent that it used to in cleaning out disease.

Q. Any compensation provided for?—A. Yes; there is a slight compensation.

Q. Would you recommend any Federal legislation on the line of more careful protection against disease in domestic animals?—A. I would recommend any legislation by which, so far as may be, disease can be kept out of the country. Forty years ago, perhaps, when pleuro-pneumonia was brought here by cattle from Europe, the board took right hold of it. The legislature saw the necessity, appropriated money, and killed every animal infected or exposed, and we stamped it out at once. It never spread beyond our borders, but was entirely stamped out in 2 years. It was very effective work and was done by the State of Massachusetts, largely through the persistence of the State board of agriculture. I think every effort should be made that no such disease should be brought into the State. This was stamped out because it was taken at the very beginning.

Q. Would a stringent law well executed to prevent disease among domestic animals have any effect upon the price of meat products in Europe or abroad?—A. I do not know how it would effect the price, but you know there has been danger that some of the markets of Europe would be closed to us because of the fear of diseased meat. I think that is unquestionably so.

Q. That complaint could only be lodged with the Federal Government, I suppose?—A. With the Federal Government.

Q. Do you know whether the present law is defective in any way in that respect?—A. I do not.

Q. Do you know whether or not our meat products have a better standing in Europe now than they had a few years ago?—A. Yes; there has been that gain.

Q. Do the farmers of Massachusetts favor free rural mail delivery?—A. They do, generally.

Q. What are some of the advantages that they think would be afforded them by that?—A. In my own town, Sutton, I live within a short distance of the post-office. I can see a great advantage peculiarly in the free delivery of the mail at my own door. It is a pecuniary advantage; it is the bringing of country life into communication quicker, easier, and more directly with the outside world. It leaves more contentment on the farm and it is better. I said in my paper before the Farmers' Congress on this question: "It seems strange that free mail delivery in rural communities is so long delayed. Not an Italian in the city but is served by the Government at least three times each day, while the native citizens in our country town, who helps to pay for this service, must at his personal cost and inconvenience get his mail as best he can. While in the business portion of this city there are 9 mail deliveries daily, the business man in the country town receives not even one. Were our Government so poor as to require this sacrifice on the part of the rural citizen we would not ask her aid. The city is to-day almost burdened by excess of service while the town is neglected. As the electric cars are speeding their way over the hills and through the valleys of New England, why should they not be utilized for carrying the daily mails to the country home? Free mail delivery is the imperative demand of the times. It is the duty of the Government to constantly broaden this service, from town to town, from village to village, from farm to farm, till this public economy becomes the law of the land."

Q. Is there any feeling among the farmers of Massachusetts in favor of postal savings banks?—A. I think there is.

Q. What advantage does the farmer expect to gain by the postal savings bank system?—A. I think they are not so interested in those banks as formerly. There is a slight interest, but I do not think it amounts to any demand in reference to it. Our banking facilities in every line are almost perfection in Massachusetts.

Mr. CLARKE. Do you think of any further statement you would like to make?—A. Only one favor I ask. Will you quote "the brighter outlook" with which I closed the address to which we have referred: "To-day the agriculture of New England is improving. Of Massachusetts I know what I affirm. In my present position I have seen new light. Wealth sees the coming change and invests for future profit. The farmer is not discouraged or downhearted to-day, but looks forward to the coming prosperity, and goes forth to meet it. He believes the undue burdens now resting on his labor are to be removed, and as never before he realizes his strength. The farmer is getting to believe in himself and to have greater faith in his brother. He realizes the dignity of his calling, its importance

to the State, its right to favor. He sees that through cooperation and united effort much can be accomplished to improve his condition and advance his position.

"Competition with the West in the great grain staples for a while led to loss and hardship, even as the West has since suffered by the competition of Russia and India; but to-day New England has found other channels of industry more profitable and better adapted to her soil, her markets, and her people. We see the fruits of summer grown in January in our own greenhouses, more profitably than in their proper season. We see our own dependent population supplied with every luxury by New England enterprise on New England soil. We see the farmer taking his old stand as a leader in all good enterprises. We see his sons, educated and strong, taking their rightful place and exerting their old-time influence, the strength of the hills, the backbone of the cities. We see the electric car speeding its way from town to town and from village to village, carrying the child to the larger and better schools and giving free mail delivery to the homes of the country as to the city. We see equal taxation resting "like the atmosphere" on rich and poor alike—every man according to his ability. We see the trusts that hold the farmers in their iron grasp destroyed or made to subserve righteous ends for the benefit of all. We see the bright day when arbitration shall settle the differences of nations, as law now settles the disputes of individuals, and war's costly tribute shall cease. We see the home in which all the comforts are found and all graces abound, its approach lines of beauty, its crown and blessing, the love and contentment that dwell therein. We see wealth of character and honesty of purpose and life honored more than gold, and honest industry more prized than the indolence of wealth. Money valued for the good it can do, 'the man the gold for a' that.' We see all this, not a mirage or a far-distant view, but growing nearer and nearer, and never hastening so rapidly to its accomplishment as to-day.

"Glance back 20 years and note the wonderful unfolding of electric power, and imagine, if you can, its undiscovered possibilities. Bottle the air we breathe into a mighty power, chill it to a wonderful agency, and realize that this is only a single vista in the glorious agencies pressing forward for the benefit and blessing of man. Let us go forth to meet the future with a firm purpose to do our duty as men, a strong faith in the fruition it is to bring to us, and a happy heart and God's blessing shall go with us."

(Testimony closed.)

WASHINGTON, D. C., March 15, 1901.

TESTIMONY OF HON. O. B. STEVENS,

Commissioner of Agriculture of the State of Georgia.

The commission met at 11 a. m., Mr. Clarke presiding. At that time Hon. O. B. Stevens, of Griffin, Ga., commissioner of agriculture of the State of Georgia, was introduced as a witness and, being duly sworn, testified as follows:

Q. (By Mr. CLARKE.) Will you please give your name, post-office address, and your official position?—A. O. B. Stevens, Griffin, Ga.: commissioner of agriculture for the State of Georgia.

Q. The commission will be pleased to hear you upon the general subject of agriculture in your State, and will be glad to have you proceed in your own way.—A. I have made a memorandum in reply to all the questions which you propound that apply to our State, and it would be better reading matter, in my judgment, just to let me reply to those questions without reference to number, for the reason that one of the questions would likely run into a preceding one. I did not make these answers as full as I wanted to make them, but simply about what I wanted to say so as to fill in as we go along. There are a great many of these questions that I have simply answered in a very rough way that I would like to add something to.

(Reading:)

"First question. The progress of Georgia on all lines of industry has been very marked during the last decade, and especially gratifying is the advancement of the State in the 2 years just passed. This is particularly true of agricultural conditions. Within the last 50 years the increase of the total population of Georgia has been 144 per cent. Considering the increase in population of the 5 largest cities—Atlanta, Savannah, Augusta, Macon, and Columbus—the increase of the urban population is 427 per cent. This percentage would be considerably increased by the addition of the population of 1 city, Athens, having 10,000

inhabitants; 1, Brunswick, having 9,000, and 11 with more than 4,000 and less than 9,000 inhabitants each, of which there is no accurate record available for 1850."

Therefore we can not compare with that year. But while we have no record, still these towns and cities have grown up since and have a very large population. So if you add these 11 other towns the increase in the urban population will be very much larger than I have given it.

(Reading:)

"This shows a considerably higher increase of the urban than of the rural population of Georgia during the past 50 years, but it is at the same time an evidence of a gratifying growth in the diversity of industrial pursuits, which argues greatly increased prosperity.

"Second and third questions. There is a larger percentage of attractive homes among our agricultural population now than at any previous time in our history. Almost every kind of improved machinery has been introduced, and within the last 2 years especially the increase in their use has been particularly marked. Of course the management of this improved machinery requires a more intelligent class of laborers than formerly. With the introduction of mowers, reapers, shredders, the best plows, and all the other modern agricultural implements, the improvement in methods of cultivation has been as great as in other sections of the Union.

"During the busy season the farmers often find trouble to secure all the necessary labor. They then send into the cities and towns and hire hands, who at that time find that they can make more working on the farm than working at odd jobs at home.

"Sixth question. The hours of labor in the field are usually from sunup to sundown, with 2 hours in the middle of the day for dinner and rest."

I state here that that is the rule, from sunup to sundown, because the ordinary laborer understands that. You gentlemen will readily understand that they do not all have timepieces, and therefore would not be able to tell when 12 o'clock came, or 6 o'clock, or any other time, but they all understand when the sun rises and when it sets, and those are the hours usually fixed.

(Reading:)

"Seventh question. Counting all the days lost by the average negro farm laborer for taking a rest, or going on excursions, picnics, etc., the average number of working days for farm hands is between 180 and 200. That may appear a little surprising to you gentlemen, but nevertheless it is true.

"Eighth question. There is a tendency among agricultural laborers to seek other employment. The young white man goes to the city to see the world, and imagines that he can there make a larger fortune in a shorter time than by engaging in the work of tilling his paternal acres.

"Sometimes the young negro goes to town induced by the promise of a little higher daily wages, not stopping to consider the fact that the increase in cash does not come near making up for items furnished him on the farm free of cost, for which he must pay out his cash in the towns. This is why so many of them become loafers, vagrants, and criminals. The remedy is: Better churches and better schools, more attractive homes and tenant houses, improved roads, and better mail facilities."

That is to say, that the more you enlighten these people, the better they do for themselves, and I know of no better way of enlightening them than that which I have suggested.

Q. (By Mr. CLARKE.) One of our witnesses suggested that if they could be brought together in little villages in the farming neighborhoods, farm life would be much more attractive to them; what do you think of that?—A. I doubt that very materially. I do not see what advantage that could be. There may be a different state of facts in his State from what there is in ours; but in the rural districts the population is very largely negroes, and there is no part of our State, except in the mountainous country where we have no negroes scarcely, in which there is not within a radius of 3 miles a sufficient number of children between the ages of 6 and 18 to form schools and churches. That fact has benefited them a great deal. I doubt whether it is better to collect them altogether. They do not do so well in our State where there are so many of them together. They do better where they are separated.

(Reading:)

"Ninth question. The best method of paying wages is by the month. Some very successful farmers adopt the plan of paying half the monthly cash wages on the first Saturday of every month, putting the rest aside until the 24th day of December."

That is to say, the first Saturday in every month the farmer pays his hired man one-half of his monthly wages, and the other half is usually set aside to be paid him on the 24th day of December. That is usually provided for in the contract.

Q. (By Mr. FARQUHAR.) Why is the 24th of December chosen?—A. That is the day before Christmas, you know, and we usually try to save up money so that they can have something for the Christmas holidays.

(Reading:)

Then the laborer, much to his delight, finds that he has money for the Christmas holidays, which would have been squandered long ago, under the plan of paying him in full each month. A few farmers pay weekly, others monthly, while a majority pay a portion of the monthly wages in either cash or trade at the stores.

"Tenth, eleventh, and twelfth questions. To every farm hand is furnished a home, a garden, fuel, water, and ordinary rations. In money the maximum pay is \$15 a month, the minimum \$3 a month. Some skilled laborers understanding well the use of improved farm machinery receive from \$1 to \$1.50 per day.

"The above methods of payment are the prevailing ones, and give the most satisfactory results.

"According to the census of 1890 the farms in Georgia cultivated by the owners were about 46½ per cent of the whole; those rented for a money value, 17½ per cent, and those rented for a share of the products, 36½ per cent.

"Thirteenth and fourteenth questions. Where the tenant system prevails the average tenant is furnished with a home, water, fuel, pasturage for his stock, a share of the fruit on the place, a garden, an outhouse for stock, and storage for crops. The sharing of the crop is usually on this plan: One-fourth of the cotton, one-third of the corn, and one-half of the small grain goes to the landlord; the balance to the tenant, the landlord furnishing the land and seed and his share of the fertilizers. These conditions vary with individuals."

Q. (By Mr. TOMPKINS.) What is his share of the fertilizers, how much?—A. Where he uses it on cotton he pays for one-fourth of it, and where he uses it on corn he pays one-third. He pays the same pro rata share that he draws for the crop.

Q. His share is then proportioned to what he gets for the crop?—A. Yes; and on grain, where they use it, they usually divide the grain profits equally—that is, wheat, oats, barley, etc.—and they divide the expense of the fertilizer.

(Reading:)

"We think the tenant system as a whole has a tendency to reduce the average production per acre of most of the crops, because a great deal is left to the management of the unintelligent negro farm hand, the landlord being interested to only the extent of his rent. Loans or advances to the tenants by the landlord are general. The landlord must furnish supplies and mules with which to make the crop. If the landlord prefers he has his factor or merchant to furnish these supplies to his tenants to be paid for when the crop is marketed, the merchants frequently taking liens on the crops of their tenants to the extent of their advances. The effect of this is that frequently the tenant pays a large and exorbitant rate of interest on the supplies or advances which he receives on time."

Q. (By Mr. FARQUHAR.) Do you care to say anything more than you have said about this crop lien matter and its disastrous operations as far as tenant farmers are concerned?—A. That system has always been the rule in our section. It is not only the rule among the colored tenants, but it is the rule with the whites.

Q. Is that system on the increase or not?—A. No, I think not.

Q. Is public opinion against it? Is not there a general feeling in Georgia that it is not entirely fair?—A. Yes; the public opinion is against renting at all. We doubt the propriety of it for the reason that the crop to a great extent and the land also are neglected. You rent your land to a man and he goes in to get what he can out of it for the least expense possible without paying any attention whatever to building up the land or saving it. For instance, you lay out your farm nicely; terrace it and fertilize it up, and rotate your crops and improve your land. The tenant and renter has no interest in your landed estate whatever. He therefore goes in to get the best crops he possibly can out of the land with the least expense, and as fast as the land gets to where it is not remunerative to him he abandons it and leaves it and goes to some other man. And for that reason we do not feel like the tenant system is what we desire; it is not the best for our country.

Q. And would you say it was bad economy both for the owner of the land and the tenant?—A. For both; yes.

Q. Is this land that is rented in this way owned by native Georgians, people that live near by?—A. Oh, yes.

Q. And they sit by and see the deterioration of this land under this cropping system and do not intervene as a matter of economy to themselves?—A. Well, yes.

land to-day? That will be true of the next generation.—A. I am glad you brought that up, because it is a very important question. I maintain it is almost impossible for a young man to-day to purchase a home at the present price of land and go in debt for the price and also for implements, horses, and cattle that he must use in order to work the farm; that if he does so, it is almost impossible for him within his natural life to become a free man; that is, get out of debt and own a farm. But when I say the farmer's boy may acquire a home, I mean the farmer's land will be divided up among his family.

Q. (By Mr. PHILLIPS.) How is it in cases where the father only owns 100 or 200 acres and has 5 or 6 children? Will that land divided among them make a competency for each?—A. That question I can answer in this way: That the family in its efforts and by the labor of its members on the homestead owned by the father are enabled to buy lands adjoining them or from their neighbors. That is the cause to a great extent of the increase in value of our land, that causing it to average a bigger price.

Q. (By Senator KYLE.) The question occurs to me whether or not it is going to be the same in Minnesota and the Dakotas as it was in Illinois and Ohio probably a generation ago. Lands in that country 25 years ago were worth what they are in Minnesota to-day probably. They are of higher value to-day. A young man was able by frugality, industry, and with good health to gain a living and acquire a home of his own, maybe not more than 80 or 100 acres; and he had to meet the problems in those days as they meet them now. A young man frequently began with nothing. He would work for other farmers for \$20 or \$25 a month, and through frugality and economy acquire a little sum with which to buy implements and teams, and by and by he would rent a farm which he would operate for 3 or 4 years and ultimately buy a piece of land of his own. Can that method be pursued now by a young man starting with nothing in Minnesota?—A. In my opinion it can not generally. There may be some exceptions to the rule, as you are aware of, from the statement that I have made, and it is beyond successful contradiction, because I have figured at the lowest price at which the work could be performed. When renting a farm we usually give half to the tenant, the owner of the land furnishing the seed and usually paying half the actual money paid for the thrashing. The price of grain given shows that he raises grain at a loss, allowing a reasonable remuneration for his time, and I fail to see, with land at \$20 an acre (which is around our country about the average price), and allowing interest at 7 per cent, where a young man is going to get a foothold raising wheat. I maintain that it is almost impossible for him to pay for his land during his natural lifetime.

Now, I venture to say that, even getting the homesteads as we have done, fully 50 per cent or more of them are already mortgaged. If that is the case, and I know it can not be successfully contradicted, then under those circumstances how is the young man that starts in with nothing—buying everything on time—raising wheat; how is he going to be able to pay for that land during his lifetime? There are, however, instances where it can be done. In those days in the older States wheat was higher. In my younger days I have sold wheat as high as \$1.37, and I might have sold it as high as \$1.50 if I had taken advantage of the market at the time. Contrast that figure with the price at 50 and 55 cents and you will find there is a vast difference in the opportunity presented to a young man now and what it was then. In the early days, also, we used the cradle. The cradle cost only a trifle. Now we use the self-binder, and it costs us from \$125 to \$135; and that, of course, we buy on time and with interest at 7 per cent. Expenditures soon count up. I remember the first self-binder I purchased. I bought it for \$300 and paid \$15 freight, making \$315 for the self-binder. That price, with 7 per cent interest added, was a good deal of money before it was paid for.

Q. (By Mr. LITCHMAN.) Have you contrasted the cost of living and other things at the time when wheat sold for \$1.37 with the price now in comparison?—A. With the exception of the few rags of clothes which we wear, we raise our own things on the farm and do not look upon our living as costing anything; of course, we raise it.

Q. The difference in the selling price of wheat is largely, even almost exclusively, taken from the farmer?—A. Yes.

Q. This difficulty that you complain of concerning the farmer's son; does not that apply equally in other parts of the country with other industries?—A. I am only speaking as a farmer and from a farmer's standpoint.

Q. The point I wished to develop was whether the general trend of affairs that operated with the farmer and the farmer's son does not also operate in other lines of industry.—A. That I am unable to answer.

Q. (By Senator KYLE.) What about the comparative prices paid for farm help

between now and 25 or 30 years ago?—A. When I used the McCormick reaper I used to pay as high as \$3 a day for laborers to bind grain. Now we pay from \$2 to \$2.50 during harvest time, which is a short period, so that we paid a little more in the earlier days.

Q. What is the average price of the wages of farm hands in your country?—A. We get along during a good deal of the time without farm help; that is, we do what is known as the chores ourselves; invariably during the winter time. If we have more stock than we are able to take care of, we usually hire a man by the year, and the usual price given a man by the year is from \$175 to \$200. When we hire men during the harvest time by the day, we pay from \$2 to \$2.50 for the actual days they work. You city people might call our day a day and a half, but we call it a day. If we hire men by the month for the busy season, say 2 or 3 months, we usually pay them \$20 or \$30 per month and board.

Q. (By Mr. PHILLIPS.) In the price per year is the board included?—A. Yes; when we hire a man on the farm the board is usually included, because we raise what he eats and we call it nothing.

Q. (By Senator KYLE.) So the average wage is from \$16 to \$20 per month by the year?—A. Yes.

Q. What was it 25 or 30 years ago?—A. It varied a little. I worked for less money 40 years ago.

Q. Forty years, yes; but how was it 25 or 30 years ago?—A. The wages are pretty near the same. They have not varied much for the yearly laborer on the farm.

Q. Is the young man getting \$200 a year with his board able to save anything?—A. He has to get his clothes from that and his shoes and washing, etc., and other incidental expenses, so that at the expiration of the year he possibly has a trifle; it may be \$100, if he is careful.

Q. (By Mr. A. L. HARRIS.) Can a farm hand do more now with improved machinery than he could 20 years ago with the machinery then in use?—A. Yes; I am glad you mentioned that. Yes; we can perform as much work to-day on the farm with improved machinery—with 1 man and a team—I might almost say as much in 1 day as we could then in 5. I am pretty positive we could accomplish as good results from 1 man driving a self-binder with 3 or 4 horses to the binder in 1 day as that man could do with his cradle in 5. That is when we used to cradle the grain and swing it in that way [indicating].

Q. Has that change reduced the cost of production?—A. It has reduced the cost of production to some extent; but, what is strange to say, in those cradling days it appeared to be as easy for the farmer to pay his lawful debts then as it is now, and if you put that question to 100 farmers, I venture to say that 99 of them would say, "much easier." Then the hours of labor naturally would decrease from the use of machinery, but it is right the reverse: it appears that our hours are as long, and if anything longer than they were in those days. Now, how can I account for that? It is impossible for me to account for it, but the facts are there, notwithstanding; there is something wrong that ought to be made right. If we do as much work in 1 day as we did in 5, the natural question would be, why do you work so long hours now?

Q. Does the farmer at the present time enjoy more luxuries than he did 25 or 30 years ago?—A. As far as that is concerned I think the tendency is to live a little better; but we do not live as well as we ought to, because we can not afford to do so.

Here witness read the following paper:

Transportation.

Owing to the advanced ground which we have taken on this all-important subject and the reversal of our policy of the past on this subject, we will not be surprised to have severe criticism leveled at our attitude by our critics and persons who have not reasoned out this great problem to an intelligent and logical conclusion.

Before declaring our position definitely it must be borne in mind that we approach this question as farmers and deal with it only in so far as it affects the products and industry of agriculture. The general belief prevailing among the citizens of this country, and perhaps throughout the world, is that any reduction in freight rates on our grain crops will go to the producer to the extent of such reduction on freight to the markets of the world.

We believe we can reasonably show that this proposition, as far as it applies to the product of wheat, is entirely erroneous. My remarks will be therefore

land to-day? That will be true of the next generation.—A. I am glad you brought that up, because it is a very important question. I maintain it is almost impossible for a young man to-day to purchase a home at the present price of land and go in debt for the price and also for implements, horses, and cattle that he must use in order to work the farm; that if he does so, it is almost impossible for him within his natural life to become a free man; that is, get out of debt and own a farm. But when I say the farmer's boy may acquire a home, I mean the farmer's land will be divided up among his family.

Q. (By Mr. PHILLIPS.) How is it in cases where the father only owns 100 or 200 acres and has 5 or 6 children? Will that land divided among them make a competency for each?—A. That question I can answer in this way: That the family in its efforts and by the labor of its members on the homestead owned by the father are enabled to buy lands adjoining them or from their neighbors. That is the cause to a great extent of the increase in value of our land, that causing it to average a bigger price.

Q. (By Senator KYLE.) The question occurs to me whether or not it is going to be the same in Minnesota and the Dakotas as it was in Illinois and Ohio probably a generation ago. Lands in that country 25 years ago were worth what they are in Minnesota to-day probably. They are of higher value to-day. A young man was able by frugality, industry, and with good health to gain a living and acquire a home of his own, maybe not more than 80 or 100 acres; and he had to meet the problems in those days as they meet them now. A young man frequently began with nothing. He would work for other farmers for \$20 or \$25 a month, and through frugality and economy acquire a little sum with which to buy implements and teams, and by and by he would rent a farm which he would operate for 3 or 4 years and ultimately buy a piece of land of his own. Can that method be pursued now by a young man starting with nothing in Minnesota?—A. In my opinion it can not generally. There may be some exceptions to the rule, as you are aware of, from the statement that I have made, and it is beyond successful contradiction, because I have figured at the lowest price at which the work could be performed. When renting a farm we usually give half to the tenant, the owner of the land furnishing the seed and usually paying half the actual money paid for the thrashing. The price of grain given shows that he raises grain at a loss, allowing a reasonable remuneration for his time, and I fail to see, with land at \$20 an acre (which is around our country about the average price), and allowing interest at 7 per cent, where a young man is going to get a foothold raising wheat. I maintain that it is almost impossible for him to pay for his land during his natural lifetime.

Now, I venture to say that, even getting the homesteads as we have done, fully 50 per cent or more of them are already mortgaged. If that is the case, and I know it can not be successfully contradicted, then under those circumstances how is the young man that starts in with nothing—buying everything on time—raising wheat; how is he going to be able to pay for that land during his lifetime? There are, however, instances where it can be done. In those days in the older States wheat was higher. In my younger days I have sold wheat as high as \$1.37, and I might have sold it as high as \$1.50 if I had taken advantage of the market at the time. Contrast that figure with the price at 50 and 55 cents and you will find there is a vast difference in the opportunity presented to a young man now and what it was then. In the early days, also, we used the cradle. The cradle cost only a trifle. Now we use the self-binder, and it costs us from \$125 to \$135; and that, of course, we buy on time and with interest at 7 per cent. Expenditures soon count up. I remember the first self-binder I purchased. I bought it for \$300 and paid \$15 freight, making \$315 for the self-binder. That price, with 7 per cent interest added, was a good deal of money before it was paid for.

Q. (By Mr. LITCHMAN.) Have you contrasted the cost of living and other things at the time when wheat sold for \$1.37 with the price now in comparison?—A. With the exception of the few rags of clothes which we wear, we raise our own things on the farm and do not look upon our living as costing anything; of course, we raise it.

Q. The difference in the selling price of wheat is largely, even almost exclusively, taken from the farmer?—A. Yes.

Q. This difficulty that you complain of concerning the farmer's son; does not that apply equally in other parts of the country with other industries?—A. I am only speaking as a farmer and from a farmer's standpoint.

Q. The point I wished to develop was whether the general trend of affairs that operated with the farmer and the farmer's son does not also operate in other lines of industry.—A. That I am unable to answer.

Q. (By Senator KYLE.) What about the comparative prices paid for farm help

Q. (By Senator KYLE.) Are there any questions upon the subject upon which he has just touched?—A. I am here to answer them, gentlemen. This seems to be a very hard question. It seems to be the prevailing opinion, not only of the American farmer, but of the world's farmers, that the lower you can bring wheat to market the better the price should be and the more the farmer ought to get; but we have only that one market. As soon as you get us another market then the results will be different.

Q. (By Mr. LITCHMAN.) How has the combination between the Great Northern and the Northern Pacific affected you?—A. I am not prepared to answer that question, because I confess I am ignorant. I do not know of any combination between them.

Q. I am speaking now of the combination announced by the newspapers.—A. O. yes; I am unable to answer that.

Q. (By Mr. FARQUHAR.) You are prepared to say that if 10 cents is eliminated from the transportation charge on your through bill of lading from the Minneapolis terminal to Liverpool the farmer gets no benefit out of that 10 cents elimination?—A. Yes; I am prepared to say, from experience, that the buyer—the consumer—is the man who gets the benefit, for the reason that we come in competition with the other wheat growers of the world, and they are at that market selling their wheat, and the price that is made in Liverpool is cabled all over the universe in a few hours. That is the established market of the world.

Q. When you sell your grain there at home, do you sell it under the quotations of the Minneapolis or Chicago market?—A. The quotations of the Minneapolis market, generally.

Q. Is the Minneapolis sale under the Chicago or New York market?—A. Sometimes the market of Minneapolis is lower than the Chicago and sometimes it is a little higher than the Chicago quotation.

Q. Your grain passes through several hands before it reaches the Liverpool market, does it not?—A. Usually; yes.

Q. And the main cost is transportation; now, suppose you make a reduction of 8 or 10 cents on the transportation, as you have spoken of in your paper, and in the commission on your through shipment from Minneapolis clear to Liverpool 6 or 7 cents commission fees is eliminated, do you pretend to say it is logical or practical or businesslike to say that it does not change your market at home and that you don't get a better price than you otherwise would for all that saving which occurs?—A. If we had another market; but we have only the one market, and the various other wheat countries of the world bring all of the wheat of the world to that market, and the consumer or the buyer in that market of Liverpool makes the price of the wheat sold. The man that sent the wheat to the Liverpool market in the first instance, might have a larger margin than he ought to have and he might by reason of that margin make his bid lower than the other people of the world that were there to sell their wheat, and he would possibly get the order; but the instant he did that the other competitors would drop in order to get the order themselves, and it would be optional after the other sellers in the world came down on a level with the price asked by the American seller, it would be optional then with the buyer at Liverpool to place his order either with the American, who first made the price lower, or with his competitors that came down to the level of his price. Hence, we maintain that if the entire freight charge was wiped out and wheat was landed in Liverpool without cost it would not add one penny to the price received by the farmer, for the reason that the seller in the Liverpool market would then offer wheat lower, and the moment he offered it lower the wheat there from the other countries to be sold would come down to his price.

Q. (By Mr. A. L. HARRIS.) You mean if freight was reduced all over the world?—A. If it was reduced all over the world, it would be different. If freight was reduced all over the world or reduced in any other country, the same as our freights here would be reduced, those two countries would have for an instant the advantage of the other countries and would receive that benefit, but the other countries would come down on their level even if they had to sell their product below cost, because there is a surplus, and it must be marketed.

Q. (By Mr. FARQUHAR.) You think if there was a reduction of 10 cents in the through bill to Liverpool on the whole wheat crop of the Northwest it would make no difference in the Liverpool market?—A. Yes; I think it would reduce the price on the wheat of the world.

Q. Do you think there are any American or English or French or German sellers in the Liverpool market that are selling and endeavoring to bear the market in Liverpool? Do you think there are any sellers from America that intend to sell at the cheapest figure they can to get rid of the grain?—A. If they have the wheat to sell, of course they want to get the biggest price they possibly can.

Q. Is it a cash product? They have paid for it and it is there on hand?—A. It is a cash product, and they have it on hand and they want to get the biggest price; but the competition is strong and there is only the one buyer.

Q. Does the one buyer supply the demand that buys in Liverpool?—A. Yes.

Q. It is the sellers of Europe that buy in Liverpool?—A. Undoubtedly; and Liverpool, being the principal market of the world, is equivalent only to one market, because it rules the price of the world's market.

Q. (By Mr. LITCHMAN.) Is it not the surplus of the product of the farmer which is sold in the Liverpool market?—A. The surplus; and I want you to understand that the surplus, though small—usually from 100,000,000 to 125,000,000 bushels in the United States—sets the price upon every bushel of wheat that is raised in the United States of America. Now, if we could wipe away that surplus and have no surplus, by procuring a market somewhere else, we would not be at the mercy of the Liverpool market as we are. That 125,000,000 surplus that we have sets the price of every bushel of wheat sold in the markets.

Q. (By Mr. FARQUHAR.) The opinions you are giving this morning here that a moderate reduction of the through bills of lading in Liverpool, that even the abolition of the entire freight rate, would work no advantage to the producer, but would naturally be a benefit to the consumer. Is that the opinion you state?—A. That is the opinion of the Grain Growers' Association. It is the logical opinion that they have formed upon this question. That is their opinion. It is not the public opinion, because, proclaiming this view as I proclaim it here before you to-day (if I made that statement four or five years ago), I would be laughed and mocked at and pointed to with the finger of scorn; but when we have logically figured out the question and followed it out to a determination we find that the consumer gets the benefit of the reduction. Take the reverse, now. For instance, if the railroads made a reduction on a carload of fuel to our Northwestern country, we would be consuming that and would get the benefit just as the consumer of wheat gets the benefit of the reduction on that article.

Q. (By Mr. PHILLIPS.) If the railroads made that reduction of 10 cents, could they not and would they not pay you that 10 cents?—A. It would not affect the local market much, for the reason that the wheat would go direct to Liverpool, where it would come into competition with other wheat, just as I spoke of in case of the reduction of a car of coal from Duluth to Graceville. If I should consume a portion of that car, I would get the benefit, not the miner that produces the coal.

Q. Do you mean that if you were allowed 10 cents more on the wheat that is shipped abroad that would affect the markets of the world and they could not afford to pay you 10 cents more or 10 cents less; that that would not affect the whole market of the world?—A. It would affect the whole market of the world, for the reason that our exporter or importer, our buyer or seller, those selling wheat to Liverpool, would give the purchaser a slight advantage over his competitors, and if he wanted to sell his cargo he would then be enabled to underbid the wheat sellers of other countries.

Q. Not if he paid you 10 cents more a bushel?—A. No; he would not be able to do it, but being, as he is, obliged to compete with the other sellers in the one market—

Q. (By Senator KYLE.) Your idea is that in case the exporter to Liverpool gets a reduction of 10 cents a bushel on what he has shipped to New York that he will use that reduction as a leverage on the foreign buyer?—A. Yes.

Q. Instead of paying it to you?—A. Yes. Not exactly that; but he is enabled to sell wheat a little lower than his competitors, and the moment he reduces the price the competitors also fall.

Q. (By Mr. FARQUHAR.) Your market, you say, is based on Minneapolis quotations. How do you know whether your wheat goes to foreign export or domestic manufacture?—A. We have no way of knowing exactly unless we ship direct to New York. That is the only way we could know, because it goes through different hands; but we do know that Liverpool makes the market for us.

Q. Suppose we leave that foreign question out. How do you know that out of the entire consumption of America here, with the small export trade, the prices in America do not make the prices for American wheat?—A. The price in America?

Q. Yes; the whole consumption price and the price that you get. How do you know that you get the foreign price at all?—A. For the reason that we raise more wheat in America than we are able to consume. Therefore the surplus must go somewhere.

Q. But the question is, Why is not the great mass of consumption in this country a factor that makes the price of American flour and wheat? Why do you bring in a foreign market?—A. For the reason that our Chicago board and our Minne-

apolis board and the Duluth board watch the cable news, and that the market is made there by them and that they are governed by them.

Q. Undoubtedly for export trade that is true, but what do they depend upon for domestic trade?—A. That export trade sets the price upon the wheat that is sold at home.

Q. You could not tell that a single bushel of wheat raised in 40 years has been ground in St. Paul or Minneapolis?—A. No.

Q. (By Mr. LITCHMAN.) Who pays the freight on wheat?—A. The farmer.

Q. How do you figure that out, then? Show that, please.—A. How do I figure out that the farmer pays the freight?

Q. Yes.—A. Why, the very reason that much less is taken ought to be enough to start in on.

Q. But you said when the 10 cents reduction on freight is made the farmer does not get it?—A. I say the farmer does not get it, for the reason that it goes to the benefit of the consumer, just as I illustrated it.

Q. Now, I will not speak as a matter of theory, but as a matter of fact. You stated that your average for 10 years was 59½ cents a bushel. That is 59½ cents at the farm, is it not?—A. Yes.

Q. Well, whatever is paid for freight is added to that?—A. Yes.

Q. Is that not paid by the buyer in Minneapolis?—A. It is paid by the buyer, most undoubtedly, in that sense, but it comes out of the wheat; the wheat is that much less.

Q. What I wanted to get at is to trace it from the farmer to the consumer. Now, then, to the price of the wheat on the farm is added the price of the freight in making the price at Minneapolis, is it not?—A. That is, you mean that, considering the transportation of the wheat from the farm to Minneapolis, the price is that much less when it gets to Minneapolis?

Q. No. What I mean is, if the price of wheat at the farm is 59½ cents and the price at Minneapolis is 70 cents a bushel, the supposition is that that difference of 10½ cents is the cost of transportation?—A. Yes.

Q. Now, then, the price at Minneapolis is fixed by two factors, is it not: the consumption in the home market and the consumption in the foreign market?—A. No. We think and believe that the home consumption has nothing whatever to do with setting the price upon the wheat, for the reason that the export wheat that is shipped abroad makes the price.

Q. Now, then, can you give the proportion? You have estimated about one hundred and fifty millions of bushels is exported?—A. From a hundred millions to one hundred and fifty millions.

Q. Can you give the total production of wheat in the United States?—A. I am not prepared to give that in figures at the present time, but approximately about six hundred millions.

Q. Then one-fifth or one-fourth goes into the export trade?—A. Yes.

Q. This amount that is exported, then, is the surplus product of America, is it not?—A. Yes.

Q. Your theory is that the selling of that one-fifth or one-fourth fixes the price for the entire production?—A. For every bushel we raise.

Q. That the law of supply and demand operates to fix the price to the farmer by the amount of the crop?—A. Yes.

Q. And the larger the surplus the lower the price to the farmer?—A. That is it exactly. That is my position.

Q. Your idea is that if the crop was only sufficient to supply the American market a higher price would be obtained for the wheat?—A. Yes.

Q. (By Mr. PHILLIPS.) Is it not a fact that in any article of export in package the freight takes nearly all the profit of those that are engaged in it: that the profit is frequently about all taken by the cost of shipping abroad?—A. You speak of flour or wheat?

Q. Flour, or anything. Is it not a fact that those that are engaged in exporting find that there are times that the freight rates go up so high, both on land and on sea—and especially on ocean freights—that there is nothing in it?—A. The exporter's profits on wheat are very small; it is a very small margin.

Q. (By Mr. LITCHMAN.) Supposing there was no market for this 150,000,000 of surplus, would it not have a very material effect upon the price obtained on the home product?—A. It would have a very material effect in reducing the price at home, because the law of supply and demand governs the price.

Q. (By Mr. A. L. HARRIS.) Suppose there are only 10,000,000 bushels to export. Does the export still have a tendency to fix prices?—A. Yes; no matter how small the export is. As long as there is a surplus left, it has a tendency to set the price upon every bushel of wheat we raise in America.

Q. (By Senator KYLE.) I take it from your testimony that you are in favor of

opening up a market in the Orient?—A. I am in favor of getting another market anywhere, so we will have competition. Is there anything under the canopy of heaven more degrading than a man's not being able to set a price upon the staff of life which he has raised? On every other product of every country in the universe, including our own, a man is able to set a price. If I go into a store for a dozen eggs I have to ask the merchant, "What are you charging for eggs to-day?" If I go to an elevator with my load of wheat I have to go the man standing behind the scale and say, "Please tell me what you are paying for wheat to-day." He replies, 50 cents or 55 cents. I drive out, not satisfied to sell, and I go to another elevator, and the man there repeats the same price. Nay, I can go north, east, south, or west 10, 20, or 30 miles, and the price is just the same. I have no more to say as to the price than the man in the moon. There is something wrong.

Q. (By Mr. LITCHMAN.) You are coming to that question of elevators, are you not?—A. Yes.

Q. (By Senator KYLE.) I think also you are in favor of the reconstruction of the merchant marine?—A. I am, because I think it is very wrong for us to be depending upon foreign bottoms to transport the product of our own labor abroad.

Q. Are you in favor of subsidizing certain American ships?—A. I am in favor of that; notwithstanding that the bulk of the tax comes from ourselves, we are still in favor of it.

Q. You speak the sentiment of the majority of the farmers in the Northwest?—A. I do. In several conventions we have had we have gone over this matter.

Q. (By Mr. PHILLIPS.) Do you think the farmers of the Northwest would be in favor of a subsidy given to the richest people in the world, and be taxed for it themselves?—A. No.

Q. Do you think they favor giving a subsidy when they are shipping their own commodities at a very large profit, as some of them are? The largest beneficiaries of the subsidy have one of the largest fleets on the ocean, and they are making a very large profit now on shipping their own commodity. Would you be in favor of subsidizing them?—A. I would be in favor of anything that would increase the American ships and open another market for our surplus crop. I would be in favor of that. I am not in favor of subsidizing to the extent of nine millions that is proposed by the pending bill, to be given only to the ships engaged in foreign trade. I am not in favor of giving any portion whatever of that to ships that would not carry freight. I would be in favor of giving only to the ship that carried the freight—that did the work.

Q. (By Mr. LITCHMAN.) And if that happened to be owned by a very wealthy corporation, provided it did the work, you are perfectly willing to give a subsidy?—A. Yes; certainly.

Q. (By Mr. PHILLIPS.) Would you be in favor of the Government's giving a large subsidy to large corporations without having anything to say in fixing the price at which they should ship, leaving that wholly to their own discretion?—A. No; under no circumstances. If they should receive the subsidy, there should be some form by which the Government should control them, so that they could not combine to raise freights.

Q. Has there ever been any law proposed to regulate freights or touch these people—to regulate freights, or to give reasonable freights?—A. I think the Sherman law would effect that, but from the copy of the bill I have seen the Sherman bill has been ignored. We, as farmers, are in favor of subsidizing American ships for the actual amount of what they carry, and no more.

Q. (By Mr. A. L. HARRIS.) You would be willing to leave the rates to competition?—A. Corporations seem to overcome competition to a great extent by uniting their forces one with the other, and therefore I think that the Government should have some control by which it could regulate freight charges.

Q. (By Mr. FARQUHAR.) You would be in favor of a bill of that kind providing the Sherman Act should be applied to that—an exact provision in the bill to that effect?—A. I am willing to be placed on record as being in favor of any bill that will open the oriental market for us and build up our American shipping, and for the actual work that is done—for the actual freight that is carried.

Q. (By Mr. CONGER.) What is the feeling of the farmers of the Northwest on this subsidy bill now pending before the Senate? Do they like it?—A. As it stands now the farmers will oppose it.

Q. What changes would they desire to have made in it?—A. The farmers desire to limit the time to 10 years of giving the subsidy, for the reason that if it should prove to be a failure and of no benefit to the farmers, 10 years is too long. If it proved to be a benefit to the farmers, then there would be nothing at the expiration of the 10 years' contract to prevent Congress extending it then to 20 years or 30 years, if it proved a benefit to the farmers, who produce 75 per cent of the freights that would be carried.

Q. (By Mr. PHILLIPS.) You alluded to Mr. Hill, of the Great Northern, lecturing before you. Is he or is he not opposed to this ship-subsidy bill?—A. Some time ago it appeared that Mr. Hill, from his speech, was in favor of the subsidy bill, but he has been before many of our large State conventions and he has heard the discussion there himself, and has also spoken, and it appears that he agrees to some extent with the farmers that this bill is not in its present state beneficial to the farmers. We find clauses that give the benefit of this subsidy bill to what is known as fast boats—10, 20, and 31 knot ships—which apparently would not be able to carry much bulky freight, if they are able to carry any at all. They would compete with the work of the farmer, which is pretty hard on the farmer. If we hire a man we propose to make him pay for everything he gets. We do not propose to give our money away to those who do not earn it.

Q. (By Senator KYLE.) Does Mr. Hill think there is discrimination against Pacific shipping?—A. We take this view of it, that we have already the European market, to our detriment to some extent, for the reason that they want to get the price of our feed lower than we want to sell it to them, and hence we maintain that subsidizing ships upon the Atlantic would be of very little benefit to us, because we have already got that market. If we get, on the other hand, ships on the Pacific coast going to the oriental markets, we believe that there we will get the benefit, and there is where we farmers—

Q. (Interrupting.) The farmers are generally in favor, then, of any benefit given to the Pacific steamships?—A. They are, and of giving it only to ships carrying freight.

Q. (By Mr. FARQUHAR.) Have you a paper on that subject?—A. I have a paper that says a little something on that. I will get to it by and by.

The witness then read the following paper by himself on elevator combinations:

"Elevator combinations.

"The existence of a general elevator combination throughout the wheat-producing belt exists to a considerable extent, to the detriment of the producing classes, for the reason that as a result of these combinations they are enabled to set the price which is paid at the local stations throughout the territory where they operate. These prices reach from 1 cent per bushel to as high as 11 cents per bushel below the price which a farmer could get for his grain if he loaded up a carload and shipped it to a terminal market.

"This system of combination exists at nearly every station throughout the wheat belt of the country where there is no farmers' or independent elevator. Often where we start one of these elevators on the cooperative plan the most intense opposition is shown by the line elevators, which bid up the price often to 1, 2, and 3 cents higher than they can get for wheat in the terminal markets, pocketing this loss and making the advantageous rates which they establish at other points make it up. If they keep up this practice long enough they in time will make the farmers' house an unprofitable enterprise, so that the farmers' or independent house will be glad to sell out and stop further continuance of an unprofitable business. And when the independent house is once out of the way the line companies exact further and greater tribute from their helpless victims, who must pay it without any redress. The line elevators will soon make up the loss which this active and hostile competition brought on them when they have a clear field to operate in.

"They are further enabled to carry on this warfare through the aid which they receive from the railroad companies of the districts where they operate. This aid is given in many ways—in the prompt and active supply of cars in the busy season; in the refusal of many roads to grant sites to farmers' elevators; in giving rebates to the line elevators on freight, which are often given by the officers of the railroads who are participants in the division of profits of the line elevator companies. Owing to the peculiar nature of these transactions, it is most difficult to reach and secure such evidence as would make a case against them and prove that which is commonly known and understood—that these conditions exist on many of the roads in the country.

"Another element which enters into this condition that gives these line elevators a great advantage is their terminal elevator facilities, which enable them to take their customer's grain for storage and charge him for it, while at the same time mixing it with an inferior grade of grain, and, when delivery comes, delivering the degraded grain to the customer, who must accept it, because the rules of the board of trade will allow the elevator to deliver such grain as long as it passes what is known as 'contract grade,' which is commonly known as 'skin grade,' or the lowest possible grade of that number or grade, while it is generally known that

the value of the highest and best grade to the lowest point of the same grade is often a difference of from 1 to 2 cents per bushel. The profit to the mixer is often greater per bushel for mixing than the profit of the farmer who spent a year's toil to produce the grain.

"The same elevators, becoming traffickers in the products of their customers, are enabled to sell futures to such an enormous extent that they can sell millions of bushels of 'wind' and charge the regular fixed charges of storage and commission on stuff that never existed, and this is done in such vast volumes that the sales of 'wind' in one day will amount to fully 600,000,000 bushels, or as much as the entire crop of this nation in one year. This amount is sold for 300 days of the year, and it is one of the greatest influences in destroying the value of farm products.

"Legislation along these lines that would prevent any combination to prevent restraint of commerce and trade would be a great boon to the farming community."

Q. (By Mr. CONGER.) When a cooperative elevator has been established, and the line elevator men bid higher for the grain, who receives the benefit?—A. Your question, as I understand it, is that when an elevator bids up the price of grain higher than the farmer's elevator could pay, who will receive the benefit?

Q. Yes, temporarily?—A. I am happy to announce that we honest grangers for once come in for benefit at that time.

Q. A little while ago you said that the price of grain at your station is about 10 cents lower than it is at St. Paul.—A. At St. Paul and Minneapolis, usually.

Q. Now, suppose the freight rate were cut in two, so that the total of charges for freight, commission, elevator charges, etc., between your local point and St. Paul were 5 cents instead of 10, would not the farmers temporarily get that benefit?—A. For probably a very short time they might temporarily be benefited, but as that wheat goes to its destination, which is Liverpool, then it comes into competition with the product of the wheat growers of the world, and then, in order to get an order, the American seller would offer part of his profit or margin that he held to get the order. The very instant that he did that the other competitors would come down. For a temporary and short duration we might possibly receive some benefit, but it would be so small that it would be impossible for us to see. Now, for instance, this 14 per cent that the Great Northern Railroad gave us in the way of freight reduction went into existence on the 16th day of July, 1898. We watched; I went myself in person and watched more particularly after that the price of wheat to see if the change in freight made any difference. To my astonishment I found that there was not any whatever.

Q. What did you make comparisons with?—A. I made comparisons upon the price paid for wheat the day before the reduction went into existence, and also made comparisons for a week later and a week earlier.

Q. Did you make comparisons with the prices in Liverpool; that is, did you compare the difference between the prices on your farm or at your station and the Liverpool price to see whether that difference had decreased or whether it had remained the same?—A. Yes. I had made inquiries as far as I could learn through the public press as to the foreign market and away from my own station. I did look into that, and found there was no difference whatever. Of course the reduction was small; 14 per cent on freights would probably not amount to quite 2 cents a bushel.

Q. Do the farmers generally in your section believe that a reduction of freight rates would not benefit them?—A. We do. Those that are connected with our organization do. We discuss this question thoroughly and ask questions the same as you people are asking me now; we ask questions of one another. Even when we are in Scandinavian settlements, where they do not speak the English language so very extensively and know more about their own language than about our language, they ask us to go away, and then they form themselves into a committee of the whole and discuss the question in their own language thoroughly, and then, coming to order again, they ask questions of us. So I know that others believe the same as I believe, and would make the same statement to you as far as their language would permit them. But generally outside of our organization they have not come to this conclusion, but still believe that a reduction of freight goes to the farmer instead of going to the consumer.

Q. What is the attitude of the railroad men of your section—what is the attitude of Mr. Hill, for instance? Does he contend before your organizations that freight rates would make no difference in the price of grain to the producer?—A. At the time he made that reduction he firmly believed that that reduction went into the pockets of the farmer, every cent of it, but he changed his views, and believes with us now that the farmer does not get the benefit of a reduction on wheat.

Q. (By Senator KYLE.) Has he offered to carry your coal into you for a less price?—A. I am very sorry to say he has not.

Q. (By Mr. A. L. HARRIS.) Have you a law in Minnesota regulating the warehouses?—A. I think we have a law regulating warehouses, but, like many other laws on our statute books, I am sorry to say it is a dead letter.

Q. Does your law draw distinction between a public warehouse and private warehouse?—A. I am not positive about that. I think the law regards all warehouses that receive grain from the public—now, I won't make this statement from a positive standpoint—but I am under the impression it looks upon them as public warehouses.

Q. Does your law permit the keeper of public warehouses to buy grain?—A. Yes; the law permits that.

Q. Does the local buyer mix grain?—A. No; that is done at the terminal elevators. That is where they do the mixing. The virgin soil produces virgin wheat, and our hard No. 1 wheat is worth more in the markets of the world, as it comes in its virginity from the soil, but the buyer in the foreign markets does not receive it, for the reason that the elevator men mix it at their terminal points, and there is a difference between the first part of the grain, which would grow full and which would be known as No. 1, and the part that barely touches No. 1. There is quite a little difference between the two, and they take this grain and reduce this higher level to the lower grade in order that they can let it out of their elevator as simply a skin grade—simply to pass the grade.

Q. Do you think the man who manages the terminal elevator should be permitted to buy grain?—A. The man that manages the terminal elevator, I think, should not be permitted to buy grain, and we will ask for legislation to that effect. I have another paper that covers that point.

The witness here read the following paper:

"Conclusions.

"In conclusion I would suggest the following remedies to relieve this condition, which, in brief, would be to extend our foreign markets into the oriental countries, where two-thirds of the inhabitants of the globe dwell and who are not our customers, nor do they to any great extent consume our raw or manufactured products. This is a first and necessary effort we must make to secure these markets. As a further aid in carrying out this first proposition I would suggest the following attendant conditions that would be necessary to make the first proposition possible and apply the other remedies to bring about conditions that would make the great industry of this nation prosperous:

"We must see that our merchant marine and commerce are restored by the building of American ships to carry our products to these new-found markets, and hold this trade when once secured. As it is at present, we have nothing worthy of an American commerce, and are dependent on foreign nations to take our products to these markets in their ships, which may often be in competition with the products of their own countries, which naturally would place this nation at a great disadvantage in reaching out into this new territory and securing our share of this trade and holding it when once secured.

"We therefore favor subsidizing American built and operated ships, and of making two classes of compensation—one for the fast ship and one for the slow or freight ship. Pay the slow ship for the actual freight she carries to foreign markets; pay double for the outward trip, but nothing for the return trip. Make the experiment for 10 years. If this aid produces new American built and operated ships, we can extend and increase the compensation to a satisfactory point to keep them up.

"Another measure that we propose is to create a trade commission of 9 members, of which agriculture shall have 3 members and labor at least 1, the balance to represent the transportation, manufacturing, and financial interests, to visit those countries and devise ways and means by which we can increase and secure their trade, etc.

"For the interior development of the interests of agriculture I would suggest the following:

"To enact legislation that will place terminal elevators under the control of the Government by appointing an inspector to have charge of these public warehouses and prevent the mixing of grain, and to prevent public warehousemen from engaging in the business of trafficking in grain or using the commodities of their customers to trade in the open markets; also to prevent their keeping the better qualities of their customers' grain and delivering the poorest grades on contract, which are generally so poor that no one desires to take a delivery.

"We desire a rigid execution of the law preventing railroads from granting

rebates to especially favored shippers, which system is used to strangle competition at local and terminal points to the detriment of the producing classes.

"We desire the abolition of what is known as trading in futures, as one of the greatest evils which have an influence in destroying the value of farm products.

"We also desire legislation that will abolish bucket shops and their peculiar and disastrous form of gambling as a destroyer of values.

"We desire the abolition of the forecast crop reports by the Department of Agriculture as one of the most disastrous elements in destroying the value of farm products by the official nature and extravagance of these reports, which very often are based on erroneous data. These reports can not be reliable or accurate until the thrashing machine has done the work and told the story.

"We approve increasing the annual appropriation for the Department of Agriculture to at least \$10,000,000 to enable it to keep pace with the importance of the greatest industry of the country and the dignity of the nation.

"We are unalterably opposed to the opening of the Nicaragua Canal and the paying out of immense sums by this nation to benefit our European competitors.

"We desire that an official inquiry of the cost of raising a bushel of grain, pound of cotton, or pound of meat be taken up by the General Government, under direction of the Department of Agriculture, as the first proposition that will be necessary in furnishing accurate and reliable data upon which to propose remedies and enact laws that will give prosperity to the industry of agriculture."

Q. (By Mr. CONGER.) Your people are opposed to the Nicaraguan Canal?—
A. Yes; I have a paper here giving our reasons for it.

The witness read as follows:

Nicaragua Canal.

"The position which I take and the action which the Allied National Agricultural Associations of America have taken on this apparently popular measure, must sound like treason when compared to the almost unanimous and popular approval given to the scheme by the daily press of the nation.

"But I am not here to say pleasant things, but to disturb the harmony of misguided approbation to one of the most far-reaching and disastrous schemes that was ever seriously proposed, and which will have a tremendous and disastrous consequence to the prosperity of this nation if consummated. And when we see what swift and tremendous strides it is making toward consummation, it is not surprising to learn the awakening among the people to denounce and oppose it, when it is found that unless the most earnest and active efforts are made by the people to rise in popular demonstration against the scheme it will become a reality.

"It is with shame and mortification as an American citizen that I view the situation and position of the United States, in which it permits itself to become the cat's paw of England or any other nation which is jealous of our increasing importance as a world power. I see the awakening of those jealous nations to a realization of the immense opportunities and natural advantages which we possess in reaching out and securing an extension of our export trade which will compel those countries that are now our only customers to pay higher prices for our food and textile products, which they must have. These new found markets will place this nation in active competition against European nations to displace their manufactured products and become permanent customers of the peoples of the world, especially in the Orient.

"Owing to our naturally favored condition as to situation and nearness to the oriental countries by several weeks' voyage (at least to Japan and northern China, etc.), it seems almost incredible that our statesmen and national officers could be brought to the pitiable condition they present to the world in this game of diplomacy. It is a mad scramble for advantage to secure the trade of 1,000,000,000 people and we are in the most favored position to secure it through ordinary business enterprise. Apparently they overlook our advantage and become so infatuated with the siren song of royal favor and approbation that they forget that they do not owe their allegiance to foreign courts and countries instead of the nation and people who elected them to look after their interests.

"What does this scheme mean to the farmers and citizens of this nation? By building this canal we at once place competing countries in a position to make a short cut across our bows and invade a commercial field which belongs to us now by every possible right of advantage.

"It reminds me of a number of rich neighbors living near each other and with teeming fields laden with all the fruits of a fertile soil and a bountiful Providence, who, in order to protect these fields from the ravages of roving herds of cattle that would soon invade and destroy them, found it necessary to fence and guard well from such invasions. Under these conditions a number of the smaller neighbors were

jealous of the rapidly growing wealth and prosperity of one of their number who had a field twice as large and more fertile than theirs. They conspired together to ruin him by going to him and inviting him to banquet at their homes, giving him such distinctions and effusive compliments and attentions that they finally turned his head, causing him to actually believe that those cunning chaps were in reality his best friends. When they got him to the point where he believed he was the great factor in the development of the community they proposed to him that the best way to advance the prosperity of the community was for him to remove the fence, build a gate in lieu thereof, and then leave the gate open so that their live stock could enter and enjoy the privileges of dividing up the products of his field. For the privilege of becoming closer neighbors and better friends they would continue to extend the same courtesies and attentions which he had enjoyed up to the present. Aye, even they would let him once in a while come within the charmed circle of royal favor. What would you think of a man that would actually do such a thing? There are only two conclusions to come to—he would be either drunk or crazy.

"What application has this illustration to the subject in question? Why, it has the most direct and important bearing on the case. Here we have the entire Pacific Ocean trade—a vast field to the west, teeming with millions of inhabitants in Asia and South America, which is fenced in by the Western Continent from our competitors, who are not situated as advantageously as we are, whose ships of commerce are roaming the wide domain of the world to secure an existence. They see that with the few ships we have at present there is a vast field for the development of our commerce, and, fearing that development will drive them from their once exclusive field, they seek to accomplish through the channels of diplomacy and cunning what they can not achieve by open and legitimate business methods.

"The Secretary of State proposes that we, the American people, should actually assess ourselves \$300,000,000 as a starter to build this canal, with the probability that it will reach \$500,000,000. If the experience with like enterprises in the past is any guide we may consider ourselves safe if we get off with the last named amount.

"Who do they intend shall pay for this tremendous undertaking? Why, of course the farmers of the country, as they pay fully 75 per cent of all the taxes. We will find ourselves occupying the position that the scholar did when he cut the switch to whip himself. But we will have done it at the cost to our own resources of several hundred million dollars, and when done will allow every nation on the earth to reach out for the export trade which we can now enjoy. And the very intensity of the competition in this condition would enable our customers to set such low prices on the products of the farm that it would destroy the possibility of ever making the industry of agriculture prosperous in any part of the world.

"If the canal must be built and will be built, with or without us, let those nations who will be benefited by it build it. In that event, whatever advantage can be secured to us as a result of opening the canal we can secure and enjoy without the necessity of paying for it. We must further remark that the locality of the proposed canal and the whole Central American territory is subject to earthquakes, which, if a disturbance should occur, would destroy in a moment what required years to build and the expenditure of hundreds of millions of dollars. Therefore, under those circumstances, I would most earnestly recommend that we should drop this entire canal matter as an American enterprise, as it would be a great damage to the interests of this nation besides leaving an immense debt on the people of the country for the benefit of other nations who are our competitors."

Q. (By Mr. LITCHMAN.) You spoke in a former paper of combinations among these elevator companies, and the injury thereby coming to the farmer. Have you had any personal experience of this nature yourself?—A. No; my own personal experience is limited on this subject, but it has been taught and discussed in our societies, and while it is hard and impossible for us to condemn those people, it was commonly known that it has existed. Now, the fact of the matter is, it is almost impossible to get such evidence as would convict those fellows, for the evidence against them is such that we can not very well get at it.

Q. Then these statements made by you are the result of conference with the organizations of farmers to which you belong?—A. Yes.

Q. More than of your personal experience?—A. Yes.

Q. (By Mr. PHILLIPS.) Are the railroads or their officers interested in these elevators to any great extent?—A. I think they are not to a very large extent; there are some of them interested, but I think they are not as a general thing interested.

Q. When the price of freight was reduced to which you referred some time ago,

you say also that the spot price of grain followed it down. Now, was it or was it not the knowledge of the shippers that caused them to offer that much less for the grain? Why should you not have had that difference?—A. I believe the shippers at that time, with the small difference that there was at our place, understood that they received a temporary benefit for that small reduction at the time.

Q. It would be very easy, for instance, when the railroads put down the price, for the knowing ones, if they were at all interested, to bid that much less for your grain, and they receive the benefit, the same as if the road had made no reduction?—A. Yes.

Q. Instead of the farmers getting it, would it not?—A. I know the farmers did not get it.

Q. They did not get it?—A. They did not get it.

Q. Somebody must have got it?—A. Somebody must have got it.

Q. That was the purchaser, no doubt?—A. Yes; the purchaser, no doubt.

Q. (By Senator KYLE.) You made some statements quite serious in nature in the paper, the third before the last. I think, in regard to combinations between elevator systems fixing the card price, etc., a uniform card price for the territory in the northwest and rebates to favored shippers, etc. Do you know of these matters of your own knowledge, or is it just a matter of common rumor among the people in that country?—A. I know to my own knowledge of one instance in Browns Valley where a party had received a rebate, but the check was sent to him in the form as labor, whereas he simply got it as a rebate. In other words, the check was for labor rendered when he had done no labor.

Q. What year was that?—A. That was the year before last.

Q. It was since the adoption of the interstate commerce law. How was it paid—in a check or in cash?—A. He got a check for it. He informed me that the party running the elevator had run the elevator for the combine, one of those old line elevators, and he said that he had got the check as a rebate; that is, running an independent elevator of his own, he got a rebate, and it was given him, he says, as a check for labor rendered; whereas, he said, he performed no labor for that, and understood it was simply for a rebate.

Q. (By Mr. A. L. HARRIS.) Is your association erecting any elevators?—A. Yes.

Q. Are they called farmers' elevators?—A. Farmers' elevators.

Q. How many have you along the line of your road?—A. We have quite a few now in my own neighborhood. We have one in Browns Valley; we have in Beardsley one; we have in Chokio one; we have in Graceville one; we have in Ortonville one; and there are a couple more elevators near there.

Q. In round numbers about how many have you?—A. In that vicinity in round numbers we have 10. But they are scattered all through; I do not know exactly the number—probably not over 150.

Q. Are they built on private grounds or on the grounds of the railroad?—A. Usually on the ground of the railroad.

Q. Do the railroads give you opportunities for building?—A. Yes; in some places they do. In some places they refuse.

Q. (By Mr. LITCHMAN.) Does not your law compel them to give you these privileges?—A. I think there is something on the statute books to that effect, but, as I have said, they have many laws on the statute books that are dead letters.

Q. (By Mr. A. L. HARRIS.) After you have your elevator in operation does the railroad give you every facility for shipping your grain that it gives to your competitors?—A. Yes. I take great pleasure in stating that so far they have been generous and kind to us in giving us facilities, such as giving us cars—I think as many as we were entitled to. Sometimes there is a car famine, when all are unable to get cars. Then, of course, while some of our people may think for that instant, not taking this famine business into account, that they may probably not be so favorable to us as they are to the old lines, I have been unable to find anything but kindness and generosity from those people. The fact of the matter is to some extent many of them seem to be in favor of encouraging us.

Q. Are your elevators located on one road only?—A. Oh, no; on several.

Q. Could you name the roads?—A. We have some elevators on the Milwaukee, some on the Great Northern, and some on the Northern Pacific; on several roads we have them.

Q. When you ship your grain to the terminal elevator, how are you treated?—A. We ship our grain from our elevators, so far, to commission men in St. Paul or Minneapolis.

Q. Do you have any trouble?—A. No; not very much. We have been favored enough so far. We have no very reasonable cause to complain.

Q. Do you get the same freight rates that your competitors get?—A. That we are unable to say.

Q. Have you sufficient facts in mind to form a conclusion in regard to it?—A. I think in some instances we do not have.

Q. Do you suppose that difference would make a profit to your competitors?—A. Yes; most undoubtedly.

Q. Do you have the same rules at your elevator that your competitors have in regard to the length of time allowed to load cars and the kind of cars you receive?—A. I think generally about the same.

Q. (By Senator KYLE.) Do you have the same rules in regard to the grading of the grain?—A. I think so.

Q. The buyers at these local elevators, your own system, determine the grades?—A. Yes.

Q. And the price to be paid?—A. Yes.

Q. These elevators are located in Minnesota and North and South Dakota?—A. Yes.

Q. Do they receive the card price each day?—A. They usually receive it oftener—three or four times a day.

Q. Where do they get the card price from?—A. They get it by wire from the commission men and dealers.

Q. Where is the terminal point?—A. We ship principally to Minneapolis and Duluth from our elevators.

Q. And the commission men or commission houses to which you sell are governed in the price to be paid by the general custom throughout the city; is that it?—A. Yes.

Q. In other words, the price paid by the elevators in Minneapolis and St. Paul is the price that is paid down?—A. Yes; I think that is about it.

Q. (By Mr. A. L. HARRIS.) Does your commission man have any trouble in regard to extra switching charges?—A. He of course goes through the same regulation as the rest. He does not have any complaint to make.

Q. Does your competitor ship to the terminal elevator?—A. Yes; as a rule.

Q. You ship now to the commission man?—A. Yes; our competitors have local elevators competing with ours at our local points, and also have terminal elevators. That is the place where they get the biggest advantage.

Q. Do they give your commission man any trouble in handling your grain when it is received at the terminal point?—A. No; we do not have any complaint.

Q. Suppose the future is a bona fide sale of grain. Have you any objection to that?—A. No; we have no objection whatsoever to anything where the stuff itself is delivered. We have no objection whatsoever to a man buying wheat to be delivered three, four, or five months from now provided the wheat is actually delivered. What we object to is the selling of hundreds, thousands, millions of bushels of wheat where never a bushel changes hands.

Q. Does that affect the price?—A. Every bushel of winter wheat that is put on the market has a tendency to depreciate the price, because of the effect upon the other fellow on the other side of the water that buys our wheat, because of the immense volumes of sales that he sees made and the immense volumes of wheat that are supposed to be in the elevators. It has a tendency to make him fear, and say, "Well, there is lots of wheat in America; we can get it; we do not need to bid the wheat up."

Q. The big grain dealers claim that when they have a surplus on hand and are compelled to carry it for a better market, the privilege of dealing in options and futures is to their benefit. What do you know about that?—A. We have no objection to them or anybody else buying or selling the real stuff. The only objection we have is to buying what is known as the winter wheat. A law should be enacted to prevent gambling or option dealing in grain.

Q. Suppose you were a large grain dealer at Duluth and you had a surplus of grain. You can not sell it even in Liverpool, or your man or your agent can not sell it there, and you are compelled to ship it. Would not the selling of a future be an insurance against loss on that shipment of grain?—A. Yes; and provided that that sale took place at the given time the contract called for and the wheat was exchanged, I think that would be all right. The fact of the matter is, I think and I believe that it would be to the interests of the farmers to have both the bucket shops and the boards of trade stop selling options. Gambling in grain is detrimental to the interests of the farmer.

(Testimony closed.)

WASHINGTON, D. C., *January 16, 1901.***TESTIMONY OF MR. A. W. PRATT.**

The commission met at 2.24 p. m., Senator Kyle presiding. At that time Mr. A. W. Pratt was sworn as a witness and testified as follows:

Q. (By Senator KYLE.) You may state your full name and post-office address.—
A. A. W. Pratt, Aberdeen, S. Dak.

Q. What is your avocation now?—A. I suppose you might say I am an agriculturist, since I have retired from the grain business.

Q. What was your former business?—A. I was general agent for the Empire Elevator Company of Minneapolis, but my headquarters were in Aberdeen. The headquarters of the company were in Minneapolis.

Q. You represented the company as a traveling agent?—A. Yes.

Q. So you are thoroughly conversant with the business of that company for a number of years?—A. Yes.

Q. How long have you been engaged in the grain business?—A. More or less for 20 years.

Q. And during all this time in the State of Minnesota and the Dakotas?—A. Yes.

Q. What have you to say in regard to the making up of the card price of wheat?—A. The price is made in Minneapolis, and telegrams are sent to Aberdeen to the representative there, that is, Mr. Jumper, and he sends out the prices on cards on the different grades of wheat. That is done in connection with telegrams. If they can not get the card there in time, they send the telegram. Both are sent sometimes.

Q. Who is it that makes up this card price?—A. It is done by a board in Minneapolis—the Chamber of Commerce—three or four men.

Q. Ordinarily all these parties are engaged in the grain business, are they?—A. I think not; but in grain one way or another; some elevator men and some commission men that handle grain.

Q. One member being a member of the chamber of commerce?—A. Yes.

Q. Is he appointed by the president of the chamber of commerce?—A. I think the appointment is made through the committee. They have an executive committee there and other and different committees, and I think it is done in that way—through a committee.

Q. What have you to say as to the make-up of the chamber of commerce and the character of the men who compose it and its rules and by-laws?—A. It is made up of some of the best men in the business. Some are mill men, some are men that sell grain on samples and some on grade, and all kinds.

Q. What can you say as to their honesty and integrity in dealing with shippers?—A. Their rules are very strict.

Q. Upon what provocation can a man lose his seat in the chamber of commerce?—A. Anything derogatory or anything ungentlemanly in the way of business; violating the rules.

Q. If a man is a grain commission man, and is known to make false bills of lading or misrepresent goods shipped to him?—A. Yes; anything of that kind is subject to criticism, and generally an examination is had, and then it is taken before the whole board.

Q. You are acquainted with the other elevator companies, I presume. Do they expel members for unfair practices?—A. Yes.

Q. In other words, if there is an attempt to deceive shippers in regard to the grading of grain and the inspection of grain, that would be sufficient cause for expulsion from the chamber?—A. Yes. I might say in connection with the chamber of commerce that mill men and commission men—in fact, business men of whatever nature—if they want to become members, are admitted by applying and going through the form of balloting.

Q. (By Mr. FARQUHAR.) Is it an open chamber of commerce, where merchants as well as grain men and millers are initiated? Are the business men proper of the city members of it?—A. Some of them; yes.

Q. (By Senator KYLE.) And the membership of the elevator companies—the men who compose them are, I presume, members of the chamber of commerce, are they?—A. Yes. In order to do any business there they have to be.

Q. You were acquainted during your residence in Minneapolis and St. Paul with the other elevator companies?—A. Yes; to a large extent.

Q. You would have been aware of any combination as to the fixing of prices between these elevator companies had there been such a combination or trust?—
A. Well, I have been pretty close to them and never saw anything of it.

Q. Have you ever heard the accusation made by farmers of the Northwest that there is an elevator trust?—A. I have.

Q. What have you to say in regard to that?—A. I have never seen anything of it. I do not think there is any trust so far as the elevator men are concerned. You would not think there was when you see them go for each other and cut prices.

Q. You think there is a rivalry, then, in a certain sense, between the companies?—A. Yes. Although the card may fix upon a certain price, we break it occasionally.

Q. Wherein does the competition consist? I do not think that has been brought out as fully as it might be.—A. For instance, if we have men doing something or other and getting more than their share of the wheat, our instructions are to get our share of it.

Q. Is not that instruction frequently sent out?—A. It is done very often, and sometimes the market will be disturbed for a month or so, and we will pay a cent to 3 cents more than we are authorized to pay in Minneapolis.

Q. Do some elevator companies take great chances in regard to the grading of grain in order to get the grain?—A. There is no elevator company that can buy wheat in the country and keep its grade up and give inspection on the grain as it is bought.

Q. The purchaser can not keep it up with the grade at which he buys it? Explain that in detail.—A. In other words, we can not buy as close in the country as we have to sell. When we go to ship the grain we do not get the grade we buy it for.

Q. Is that quite the universal custom?—A. It has been so for several years, but not always to the same extent. Sometimes there is a great deal of wheat the character of which it is pretty hard to decide. It is difficult to say whether it shall go as No. 1 or No. 2, and they will take the chances on No. 2, when in Minneapolis the wheat will not grade.

Q. Sometimes you will take the chances and grade No. 3 wheat as No. 2?—A. Yes; and sometimes they grade No. 2 as No. 1.

Q. (By Mr. FARQUHAR.) You do that always with this fact in view—that the final grading is the Minneapolis grade?—A. We do not always pay attention to the Minneapolis grade. With the facilities in Minneapolis, with terminal elevators, they can fix it a little better when they get it down there. You see, we buy the wheat in the dirt; it comes right from the machine, and there is a dockage of whatever in the judgment of the different buyers is proper, and the dirt is docked out. Some buyers, for the sake of getting the wheat, will not charge as much dockage as there is, really, in it; and there are different ways in which to create this feeling between buyers and disturb matters.

Q. (By Senator KYLE.) The criticism is often made that there is a combination between the railroad companies and the elevator companies, and that there is favoritism shown to the elevator companies as against the individual shippers and the farmers' elevators. Do you know anything about that?—A. No; I do not know anything about that at all. When the wheat is coming in lively the railroad companies are anxious to keep their rolling stock out of the way and not get a blockade; and sometimes an elevator that can load the cars right up quick and start it off may get something of that kind, but not as a rule.

Q. (By Mr. FARQUHAR.) That is a matter of accommodation by the railroad company?—A. You take a farmer that wants to load his own wheat, for instance, and wants to be 2 days about it when you can load a car in 20 minutes, that circumstance, of course, would come in.

Q. (By Senator KYLE.) Have the railroad companies, in your opinion, accorded the usual favors to farmers who want to ship their own wheat?—A. The "elevator" men have kicked about the way the railroad companies use them. There is "kicking" both ways, as far as that is concerned.

Q. What would you say as to the farmers coming out better by shipping the grain themselves?—A. That depends on the quality of the wheat; the farmer that ships his wheat when out of condition gets left. There is wheat going into Minneapolis that the elevator men do not want to buy, but we are forced to buy it. It takes a good deal of work and time to get it so that it will lie still in the bin—keep from heating. We have to handle it over a good many times.

Q. Have not the elevator systems means for drying wheat?—A. Some have. Q. They are fixed so they can buy the damp wheat?—A. Yes; they can buy it, but they would rather somebody else should buy it; they let the other fellow take it as a rule. There is a good deal of wheat in Minneapolis that is not sold on grade, but by sample. There is wheat just off No. 1, but when the grade is established there they turn it over and that is the end of it. They have sold the wheat to some milling concern, perhaps, and it goes directly into the mill if the mill has capacity, and if not it is put into the elevator. That wheat is sold by sample, and

sometimes it will bring within a fraction as much as though it passed the grade. It is so with the lower grades of wheat. There are elevators in Minneapolis that do nothing else but buy this low grade of wheat and handle it with dryers. The regular elevator companies turn it over to them; sell it to them rather than put it in their own houses.

Q. The farmer is safe only when he knows that his wheat will pass inspection?—

A. Yes; when it is good No. 2 or No. 1 and perfectly dry. In the early days of shipping we used to ship about 500 bushels in a car. Twenty-four thousand pounds was about the weight; now we put in 800 and 900 bushels of wheat. A cent or 2 cents difference each on a thousand bushels of wheat, you see what that means, and the farmer gets that in case he ships it. That would be \$10 a car. The money in the elevator business is not all made in buying wheat in the country.

Q. Where, in your judgment, is it made, then?—A. For instance, May wheat is 3 cents above the present market. The elevator men buy the wheat and sell it for May and get what we call the clearing charges. They have the house room, storage, and can carry it, and that difference between the price of cash wheat and future wheat makes a little profit over and above the interest on the money.

Q. (By Mr. PHILLIPS.) When they sell wheat in advance they sell subject to elevator charges, do they?—A. They will turn around and sell so much May wheat. It is not the actual wheat. They sell that May wheat and when the time comes around they sell the cash wheat to the other parties.

Q. They have to pay the carrying charge on it just the same as if it was the same wheat?—A. Oh, if it is their own house, I do not know.

Q. (By Senator KYLE.) How does the present method of marketing grain compare with the old custom of 25 or 30 or 40 years ago?—A. It is not changed particularly.

Q. Except that now the elevator companies have their agents in the field?—A. When I was first in the wheat business Milwaukee was our market; we shipped to the commission houses in Milwaukee. Afterwards, for wheat from the South and Southwest, Chicago was the market and Minneapolis was our market. Of late years Minneapolis has become our market, whereas years ago it went to Milwaukee, that being the principal market for the West.

Q. Was it not a custom 25 or 30 years ago for country buyers to buy up grain and ship it on their own responsibility to elevator companies?—A. A good many of them did. They would put up cheap houses along the track, and the merchants themselves would buy the wheat and ship it. The country people did not do very much of that business.

Q. I would like to know something about the system of handling grain then.—A. It was done by sample. Now they take about 57 pounds No. 1, 58 pounds No. 1, and so on down. In the country we buy by sample. A man that is handling wheat all the time can pick it up in his hands and tell, and it is not necessary to make any test whatever.

Q. But complaint is sometimes made under the modern system.—A. Yes; they will test the grain for any farmer that wants his grain tested; but it is very seldom a farmer will ask to have the wheat tested.

Q. I have heard of some cases where parties would have wheat graded No. 3, for instance, and would haul it to another town and have it tested, and it would go a grade higher, and they would get considerably more for it.—A. I think they did not do it by test, but by judgment.

Q. Is it a matter of judgment on the part of the agent of the elevator company?—

A. Yes. As I say, I am not in the elevator business at present, but I have been when the elevator companies have come into contact with mills that have elevators of their own alongside those of the grain men. The Watertown mill and others have elevators right alongside the elevator men buying for the Minneapolis market. They are country millers who did not get enough at their own station, where the mill is.

Q. What about the mixing of grain at terminal points? Do elevator companies get the advantage of the farmer in this way?—A. They help their grain by handling it.

Q. The charge is sometimes made that they take 1 car of No. 1 and mix it with 3 or 4 cars of No. 3 and make good No. 2 wheat. Do you know of that being done?—A. They do to some extent, but they do not do a great deal of it. They have to clean the shrunken wheat out of it to make it.

Q. It is all cleaned?—A. Oh, certainly; it all has to be cleaned, and if there is shrunken wheat in it, they have to take out the shrunken wheat and dirt.

Q. (By Mr. FARQUHAR.) Is the mixing done in the case of home-milling wheat or export wheat?—A. The wheat which the mills will take without mixing they will sell to them, if they will take it in that way. It is mainly export wheat they mix.

Q. (By Senator KYLE.) What can you say about the possibility of shipping wheat direct to Europe?—A. There have been some schemers who thought they could ship the original wheat and keep it separate, car for car, until they got to Liverpool; but it is impossible.

Q. Why is it impossible?—A. On account of the convenience in carrying it.

Q. (By Mr. PHILLIPS.) It is necessary to mix it on shipboard?—A. It is mixed before it gets on the ship. It is generally shipped—the whole cargo—in bulk, and is mixed before it starts.

Q. Is the price of your wheat fixed at Minneapolis now?—A. Yes.

Q. And not at Liverpool?—A. Not at Liverpool.

Q. You do not believe, therefore, that Liverpool fixes the price of wheat for the United States?—A. I am inclined to think it does to a large extent.

Q. (By Senator KYLE.) In other words, the surplus crop fixes the price of the wheat at home?—A. Yes.

Q. (By Mr. PHILLIPS.) You mean to say the small surplus will fix the price of all the wheat in this country? Would the small amount that is shipped abroad, compared with what is consumed at home, fix the price of all our home wheat, do you think?—A. I think that Liverpool is a large factor in the price of wheat in the United States. You take the Argentine Republic and India, and those other wheat-producing countries, and whenever they begin to throw their wheat into Liverpool we have to come into contact with them.

Q. If you were to get, say, 5 or 10 cents a bushel reduction in freight rates from your home market to New York, would you not get the advantage of that when the wheat was sold in Europe?—A. As far as we people are concerned, we rely entirely upon Minneapolis. Now, if Liverpool advances you will find it will affect Chicago and either the Southern or Southwestern cities, and that affects Minneapolis to a certain extent; but at the same time Minneapolis will be above Chicago simply upon the local trade and local demand.

Q. (By Mr. PHILLIPS.) But you believe that a reduction in the freight rates would benefit you in the price at Liverpool, do you not?—A. I think so.

Q. As a reduction does in all commodities shipped across the ocean?—A. Yes.

Q. The price of freight must necessarily be taken from the price of the commodities sold in Liverpool?—A. Yes.

Q. (By Senator KYLE.) At what price can a farmer afford to raise wheat in the Northwest, on an average?—A. He ought not to get less than half a dollar.

Q. You think he can raise wheat at a profit selling at 50 cents a bushel?—A. I think so.

Q. (By Mr. FARQUHAR.) Does not that depend on the number of bushels of wheat to the acre?—A. Of course it does.

Q. (By Senator KYLE.) Fifty cents an average right through?—A. Yes. They would not be getting rich at that price, but they can live out of it.

Q. (By Mr. PHILLIPS.) If that was the average price for the last 10 years, it would make a living rate for the farmer, would it?—A. Yes; it would give him a small margin.

Q. (By Senator KYLE.) Since your retirement from the elevator business you have observed the condition of the farmers throughout our Northwestern country, have you not?—A. Yes; and have been advised to go into diversified farming.

Q. Tell us about what some of your impressions of the conditions of the farming classes are, compared with their former conditions—whether they are better than formerly, and if so, why.—A. I think the farmers are feeling better and getting better and doing better in every way. I think they are feeling better and are in better shape financially than they were.

Q. Why is this?—A. They farm a little differently, a little better, and are diversifying, going into farming in different directions, mixing it up a little more, raising stock of different kinds.

Q. (By Mr. A. L. HARRIS.) Have you any milling in transit rates from your place?—A. We have had, but being out of it at the present time, I could not say.

Q. Minneapolis is really your point of consumption?—A. Yes.

Q. Have freight rates fallen in the last 10 years?—A. Yes; and every time the railroad reduces the rate the reduction goes into the producers' hands; that is, prices are better. The lower the rate, the more the farmer gets for his products.

Q. (By Mr. FARQUHAR.) What terminal points do the buyers that buy wheat in your section reach?—A. Minneapolis, principally. We ship sometimes to Duluth, outside of our terminal. We ship to Minneapolis, and then without unloading forward right on to Duluth.

Q. Have you any Milwaukee and Chicago buyers up there?—A. No.

Q. Then mainly your price is set by Minneapolis people, is it?—A. Yes.

Q. In the case of a small visible supply of grain up in that section, is there any competition at all that comes from Duluth buyers and others that want to make

foreign cargoes:—A. No. If the Duluth market is better than the Minneapolis market, as far as our line is concerned, the wheat goes to Minneapolis, and some cars follow right on to Duluth. It saves their coming down here; the head of the firms at Minneapolis will order it up to Duluth; they can make a deal with the Duluth people any time.

Q. So your farmers do not get any advantage in the competition of terminal points competing for this grain?—A. Well, we have the Great Northern road, local buyers on Mr. Hill's road, that buy for the Duluth market on that line. They very seldom send to Minneapolis, but send to Duluth.

Q. (By Mr. LITCHMAN.) Would you feel the benefit of that competition unless it remained for an appreciable length of time—that is, with the farmers?—A. No; that varies. If they want the wheat for some purpose in Duluth, and raise prices, we let them have it.

Q. But it goes through Minneapolis, and not direct from the farmer, as a rule?—A. No; it doesn't go direct from the farms unless the farmer will ship it up to Duluth, which he can do if he has facilities.

Q. Suppose a farmer is not financially able to hold on to his grain; has he equal facilities for getting that grain to market?—A. Yes; he can load it right into the car. He has not the facilities, because he has to haul it and handle it by hand. He can not do it by machinery, as his elevator can.

Q. You think there are no obstacles placed in the way of the farmer getting his grain to market by reason of his being an independent operator to that extent?—A. No.

Q. In that connection will you state to the commission something about the custom of sorting wheat in the elevators, and the extent of the practice?—A. Well, a man puts in his wheat, and they give him a storage ticket of the cost, or he pays him the cash.

Q. Can you tell something about the storage charges of the elevators?—A. There is no charge for the first 15 days. Some buyers sometimes will forget the day it is put in and let it run a little longer than that, and he will get the storage maybe 30 days for nothing.

Q. Is there an advantage to one person given by that lapse of memory?—A. I presume so; sometimes he gets into trouble.

Q. (By Mr. A. L. HARRIS.) When is the better time of the year to sell wheat?—A. My opinion is that early sales are the best; right from the machine to the market. There are some farmers who lay wheat in, and if they want to carry wheat they will turn around and put in 5,000 bushels of wheat. I myself decline to carry it ahead. Those who pursue that course then have the money to use; there is no shrinkage, no loss.

Q. You think the good business farmer will sell his grain when it is ready for market?—A. Yes. There is no grain man on earth that can tell the future of grain, as far as my experience goes.

Q. (By Senator KYLE.) He is not compelled to sell in the fall?—A. No.

Q. He can store it? Tell about the storage charges.—A. As I say, it is stored 15 days free, but after that I think the storage charge accumulates. It runs up until it accumulates to 4 cents a bushel, and there it stops. That was the old rule.

Q. That is about one-half a cent a month?—A. Somewhere about half a cent a month.

(By Mr. A. L. HARRIS.) Suppose the farmer has his own granary which is the best time to sell?—A. I have tried it both ways, and I think I would sell right from the machine if I could.

Q. What effect does the dealing in futures at option have upon the present prices, the spot price of wheat?—A. I do not think it has very much to do with it. It is guesswork at the best. You can think wheat is going up, and turn around and buy it, and you will make a mistake; but I do not think the practice governs the cash price.

Q. Doesn't it affect the spot-cash price?—A. The elevators, as I said, get a lot of wheat on hand, and if the future wheat is high, they, not wanting to carry that wheat themselves, turn around and sell, to be delivered in January, February, March, down into May, and that gives them a little profit; but as a rule the elevators themselves do not carry any wheat for speculation. It is simply to protect them on their purchases.

Q. What effect does what is called "wind" wheat have on the market?—A. I do not think it has any effect on it.

Q. (By Mr. LITCHMAN.) Did not the Leiter-Armour deal have some effect on the price of wheat?—A. It did, but not to the extent that it might have had, from the fact that our people had been grading so loosely and paying the farmer so liberally on his wheat that we could not ship to Chicago and get a grade on our wheat.

Q. There was some advantage, however, was there not, to the farmer?—A. Yes;

they came up near the margin and paid just what the wheat is worth, without any profit, of course; but they do not propose to pay out any more than that. But, as I tell you, the Western people were hampered on that Leiter deal, because we could not get the grain. It was tried, and the inspection was so rigid in Chicago we dropped down, and we could not get in on the deal that helped Mr. Leiter out.

Q. (By Mr. A. L. HARRIS.) Have your local elevator men money of their own to move your wheat crop?—A. Yes, to a large extent; we have to borrow some.

Q. Do they realize quickly on it?—A. Oh, yes. We get money very reasonably. We do not have to pay but the current rates, generally. Wheat receipts are the best security with money loaners and capitalists. At one time there was any amount of Montreal money in Minneapolis for the wheat business.

Q. (By Mr. FARQUHAR.) How is it now?—A. There is some there.

Q. How is it in Duluth?—A. I presume it is the same way.

Q. What was the reason the banks of Montreal went in there—because the American banks did not have the money?—A. I suppose they had more money than they could handle at home.

Q. But was it not practically an advantage to the farmers to get that cheap money?—A. I do not know—very indirectly.

Q. In other words, when the Canadian banks came in and took up that Western grain and moved it, was it not an advantage to the farmers?—A. Yes; it enabled the elevators, with the vast amount of money that there was at their disposal, to act, and it helped to continue business. Nobody was out of money, but all always had money to pay for everything, while if money was scarce and hard to get, they might have had to knock prices down and to have done something to stop receipts.

Q. (By Mr. C. J. HARRIS.) At a cheap rate of interest the farmer can either sell his wheat in September or he has got his storage receipt and can hold out to June?—A. Oh, yes; he could get rid of his wheat some way, or get either storage certificates or something of that kind; of course he is not hampered altogether.

Q. He would not in that condition of affairs be compelled to sell out his wheat for immediate necessities?—A. No; because he could store the wheat and take receipts and give them to the bank. Our bank is very glad to get these local wheat checks, and they put them in and borrow money to carry the wheat themselves.

(Testimony closed.)

WASHINGTON, D. C., January 17, 1901.

TESTIMONY OF MR. S. H. JUMPER,

Postmaster at Aberdeen, S. Dak.

The commission met at 10.35 a. m., Chairman Kyle presiding. At that time Mr. S. H. Jumper, of Aberdeen, S. Dak., was introduced as a witness and, being duly sworn, testified as follows:

Q. (By Senator KYLE.) Please state your full name and address and occupation?—A. S. H. Jumper, Aberdeen, S. Dak. My present occupation is postmaster and farmer.

I have prepared two tables, one of them relating to the prices that have been paid to farmers for their wheat for the past 8 years, and I have arranged the prices, averaging them monthly. This table might be used for North Dakota, and can be used for Minnesota by raising the figures for North Dakota 2 cents and for Minnesota about 5 cents, because the average price in North Dakota is about 2 cents higher than the average price in South Dakota, on account of being a little nearer the Minneapolis market and still nearer the Duluth market, which is usually about 1 or 2 cents higher than the Minneapolis market.

Q. These are the rates upon wheat at the initial point?—A. At the initial point; yes. The price in Minnesota paid to the farmers will average about 5 cents higher than that paid in South Dakota, according to this table, because Minnesota lies very much nearer the markets and freight is very much less. Before presenting the table, I might tell you something about how the price is made in the three States; the card price I speak of, now, that is paid at the different stations. After the schedule between the different stations is once adjusted—and they are adjusted according to the difference in freight—the price at one station will be lower or higher than at another station, according as the freight is higher or lower. After that the prices are made by an advance or a reduction, never less than 1 cent, although the market at the terminal points might advance or be reduced.

one-half a cent. As I understand it, there is a committee of three at the chamber of commerce in Minneapolis one who represents the chamber of commerce—I think he is one who has no direct dealings with buying of wheat; another one is appointed from the elevator men, and is particularly interested in the buying of wheat, and the third is appointed from the commission men, and, as I understand it, the commission men are rivals of the elevator men. A little after the adjournment of the Board of trade, or whenever trading is over, at 1.15 p. m., these three men get together at once in a little office they have in the chamber of commerce, where they have a clerk, and agree whether the price shall be advanced or reduced throughout Minnesota and the two Dakotas. If the price has advanced on the market that day 1 cent, their clerk immediately wires this advance into the country. The different lines of elevator men do not wire this to their own men; this clerk wires it. Now, I will illustrate how this is done by telling you how it is wired to our district. It is wired to Aberdeen, and Aberdeen is the center of a district about 200 miles east and west, and 125 miles north and south, taking in a large part of South Dakota and a small part of North Dakota; and this price then goes to this territory from Aberdeen, and is sent by a person there that they have employed at Aberdeen. I think that is an explanation of about the way the price is made.

Q. Do you know who the party is that represents the chamber of commerce?—A. No.

Q. Do you know whether he is a grain man or not?—A. I have understood he is not. Probably he is a speculator. There are a great many members of the chamber of commerce who do not have anything to do with the elevator lines and are not commission men.

Q. Is it a speculator in wind wheat that represents the chamber?—A. Yes.

Q. The question arises how much the wind wheat has to do in regulating the card price?—A. The card price is always fixed by the price on track at the close of the market—by the wheat on track.

Q. (By Mr. LITCHMAN.) Is that fixed by the price at which the wheat sells during the day?—A. Yes.

Q. Then, if the wind wheat should carry up the price during the day, the wheat on track would get the benefit of it?—A. Yes; wind wheat has much to do with the actual price of the wheat on track and the price paid to the farmers.

Q. If, during the day, the speculation should carry up the price of wind wheat on the market, what would be the effect on track wheat?—A. I think wheat on track would advance just the same.

Q. You think it would be advanced?—A. I do think it is advanced by the price of wind wheat.

Q. (By Mr. A. L. HARRIS.) The wind wheat is future wheat, is it not?—A. Always.

Q. (By Mr. FARQUHAR.) Is the man that represents the chamber of commerce appointed or elected?—A. I guess he is appointed by the president of the chamber of commerce. I do not think this committee have so very much power, because the grain men wish them to keep the price at just about such a margin between the selling price and the price they pay; that is, they endeavor to have the price paid to the farmers about 3 cents plus the freight less than the cash price on track in Minneapolis; and I have noticed for 10 years that invariably when there is an advance of a cent, and sometimes when there is an advance of half a cent, if the margin is a little too large, they will advance our market a full cent. We will say, if there was a reduction of a half cent and the margin was a little too narrow the day before, they will reduce it a cent.

Q. (By Senator KYLE.) What has been your observation in regard to these margins for a number of years? Are they operating on a smaller margin than formerly?—A. No; the margin will vary from year to year as the grade of the wheat is better. This year the margin is larger than usual, because the wheat is very poor, and the No. 2 wheat will mostly grade No. 3 when it gets into the market this year.

Q. (By Mr. LITCHMAN.) What is that due to?—A. Due to getting wet after being harvested. It was a wet fall, and the wheat was badly damaged.

Q. (By Senator KYLE.) Is it true that the wheat was spoiled and dumped into the elevators, so that the elevator men do not want to take the chance?—A. No; if the crop is first-class, good wheat, the margin is sometimes a good deal less.

Q. (By Mr. LITCHMAN.) What is the amount of that margin?—A. It will average about 3 cents, and it is the endeavor of the elevator men to keep the margin at about 3 cents.

I have prepared this table from records that I have in my office at Aberdeen, commencing with the first of August, 1893, and running down by years. I have commenced with the first of August because that is the commencement of our

crop season. The new wheat commences to move in August, and if you average it through that year you have the average of the price of that crop. It runs into part of two years.

The price paid August, 1893, was 39 cents. September, 1893, the average was 46 cents. October, 1893, 44 cents. November, 1893, 43 cents. December, 1893, 44 cents.

January, 1894, 44 cents. February, 1894, 42 cents. March, 1894, 44 cents. April, 1894, 47 cents. May, 1894, 45 cents. June, 1894, 44 cents. July, 1894, 42 cents. I would like right now to add a little something here to my remarks I made before. I have prepared this table on the price of No. 2 Northern, as our crop will average about No. 2, taking the No. 1 and the No. 3 and the rejected and bringing them together. It will average about No. 2. The average for the year was 43½ cents. The average for 6 months, that is, from August to February 1, as nearly all the crop is sold by that time, is 43 cents. Commencing with August 1, 1894: August, 40 cents. September, 1894, 40 cents. October, 1894, 41 cents. November, 1894, 44 cents. December, 1894, 43 cents.

1895.—January, 1895, 43 cents. February, 1895, 42 cents. March, 1895, 44 cents. April, 1895, 44 cents. May, 1895, 50 cents. June, 1895, 61 cents. July, 1895, 56 cents. The total average for the year is 46 cents and for the first 6 months, 42 cents. The principal part of the crop, of course, is sold in the first 6 months.

1895-96.—August, 1895, 46 cents. September, 1895, 38 cents. October, 1895, 40 cents. November, 1895, 38 cents. December, 1895, 39 cents. January, 1896, 40 cents. February, 1896, 46 cents. March, 1896, 45 cents. April, 1896, 46 cents. May, 1896, 44 cents. June, 1896, 45 cents. July, 1896, 40 cents; making the average for the year 42½ cents and for the first 6 months 40 cents.

1896-97.—August, 1896, 39 cents. September, 1896, 43 cents. October, 1896, 51 cents. November, 1896, 62 cents. December, 1896, 63 cents. January, 1897, 61 cents. February, 1897, 57 cents. March, 1897, 56 cents. April, 1897, 55 cents. May, 1897, 57 cents. June, 1897, 55 cents. July, 1897, 59 cents; making an average for the year of 55 cents and for the first 6 months of 53 cents.

1897-98.—August, 1897, 73 cents. September, 1897, 72 cents. October, 1897, 73 cents. November, 1897, 72 cents. December, 1897, 76 cents. January, 1898, 76 cents. February, 1898, 81 cents. March, 1898, 79 cents. April, 1898, 88 cents. May, 1898, \$1.21. June, 1898, 86 cents. July, 1898, 70 cents; making the average for the year 80½ cents and for the first 6 months 74 cents.

1898-99.—August, 1898, 55 cents. September, 1898, 47 cents. October, 1898, 48 cents. November, 1898, 48 cents. December, 1898, 49 cents. January, 1899, 55 cents. February, 1899, 55 cents. March, 1899, 53 cents. April, 1899, 55 cents. May, 1899, 56 cents. June, 1899, 58 cents. July, 1899, 54 cents. Average for the year 53 cents and for the first 6 months 50 cents.

1899-1900.—August, 1899, 54 cents. September, 1899, 53 cents. October, 1899, 53 cents. November, 1899, 49 cents. December, 1899, 48 cents. January, 1900, 49 cents. February, 1900, 50 cents. March, 1900, 50 cents. April, 1900, 51 cents. May, 1900, 51 cents. June, 1900, 60 cents. July, 1900, 62 cents; making the average for the year 52½ cents and for the first 6 months 51 cents.

1900.—August, 1900, 59 cents. September, 1900, 52 cents. October, 1900, 59 cents. November, 1900, 57 cents. December, 1900, 53 cents; making an average for the 5 months of 58 cents.

Q. (By Senator KYLE.) Now read the yearly averages right through from 1893.—A. The crop of 1893 was sold for 43½ cents; of 1894, for 46 cents; of 1895, for 42½ cents; of 1896, for 55 cents; of 1897, for 80½ cents; of 1898, for 53 cents; of 1899, for 52½ cents, and of 1900, for 58 cents.

Q. (By Mr. LITCHMAN.) How do those prices compare with the futures or speculative prices on the wheat exchange or chamber of commerce?—A. The price of wheat on track in Minneapolis is usually from 1 to 3 cents less than the distant future. At the present time the price of wheat on the track is 1½ cents less than the May price in Minneapolis. Sometimes, when there is a good market, what you call a scarcity of wheat, the cash price in Minneapolis will be higher at this time of the year than the May price.

Q. The reason why I asked the question was to see whether the speculative price in any way benefited the farmer by indirectly raising the price paid for track wheat. A. The cash price on track keeps about the same distance from the futures during the season.

Q. (By Senator KYLE.) Have you material bearing upon the cost of production of this wheat?—A. Yes. The second table that I have prepared, and it is from actual records that I have in my office, relates to the cost per acre to raise wheat and market the same; and I wish to say that these prices will vary quite a little and they will be quite a little less than the prices given by Mr. Moran, of Minnesota, as we base our prices on wheat headed and put in the stack, while he based

his prices on wheat cut by the binder, then shocked, and then stacked, and thrashed from the stack, which is quite a little more expensive, possibly \$1.25 an acre more. Then in his average he has figured interest on the value of the farm, which I have not. I have made mine up commencing with the preparing of the ground and ending with the wheat at the elevator, figuring nothing for interest on the value of the property.

Q. (By Senator KYLE) Allowing the ordinary cost of help?—A. Ordinary good wages: such wages as I actually paid during those years and the average that was paid. In 1898 the average cost of wheat production was \$3.45 per acre. The average yield per acre was 8.5 bushels. The amount per bushel the crop sold for—that is, the average, according to the table—was 41 cents. The value of the wheat per acre was, therefore, \$3.66. The profit was 21 cents that year per acre. The total production in bushels was 21,530,000. The value in dollars was \$8,823,600. The margin taken by elevators buying wheat, with Minneapolis or Duluth as the market, was 3.2 cents. That is the margin less the freight.

1894.—The cost of production was \$1.25. The average yield per acre was 6.6 bushels. The amount per bushel the crop sold for was 43 cents. The value of the wheat per acre was \$2.76. A loss of 49 cents. The total production that year was 15,930,000 bushels. Value in dollars, \$6,690,600. The margin taken by the elevators was 3.4 cents. The crop was very poor that year, and that accounts for the large margin that the elevators took.

1895.—Cost per acre, \$3.80. Average yield per acre, 12 bushels. Sold for 40 cents. Value of wheat per acre, \$4.80. Profit of \$1 per acre. Total production in bushels, 29,260,000. Value in dollars, \$11,704,000. Margin taken by elevators, 3 cents.

1896.—Cost per acre, \$3.90. Average yield per acre, 11.2 bushels. Price the wheat sold for, 53 cents. Value of wheat per acre, \$5.93. Profit of \$2.03. The crop was 27,580,000 bushels. Value in dollars, \$14,617,000. Margin taken by the elevators, 3.3 cents. That was a very good crop. The amount taken by the elevators will average more than the year before.

1897.—Cost per acre, \$3.95. Average yield per acre, 8 bushels. Sold for 74 cents. Value of the wheat per acre, \$5.92. A profit of \$1.97. Total production, 21,440,000 bushels. Value in dollars, \$15,865,000. Margin taken by elevators, 3 cents.

1898.—Cost per acre, \$4.25. Average yield per acre, 12.4 bushels. Amount per bushel sold for, 50 cents. Value per acre, \$6.20. Profit of \$1.95. Total production in bushels, 42,040,000. Value in dollars, \$21,020,000. Margin taken by elevators, 3.1 cents.

1899.—Cost per acre, \$3.90. Average yield per acre, 10.7 bushels. Sold for 51 cents. Value per acre, \$5.45. Profit, \$1.45. Total production, 37,720,000. Value in dollars, \$19,241,000. Three cents margin taken by the elevators.

1900.—Cost per acre, \$3.70. Average yield per acre, 6.9 bushels. Sold for 58 cents. Value per acre, \$4. Profit, 30 cents. Total production, 20,140,000 bushels. Value in dollars, \$11,681,000. Margin taken by elevators, 3.4 cents.

The average cost of production was \$3.77. Average yield per acre, 9.5 bushels. Average amount per bushel crop sold for, 52 cents. Average value of wheat per acre, \$4.84. Average profit for eight years, \$1.05. Average production in bushels, 26,830,000.

Q. (By Senator KYLE.) On 160 acres what is the average amount raised by the farmers through our section of the country?—A. I should think it would be 1,200 or 1,250 bushels through our section.

Q. About \$275 clear profit on the wheat, allowing good wages for hands and teams?—A. Yes; these are figured on good wages, what you would have to pay in our section. The principal difference in these amounts is in the yield per acre. Of course, 12 bushels would cost more for threshing, but, on the average, the cost of putting it in and harvesting it is about the same. The prices are a little more the last 2 or 3 years, because wages were higher.

Q. You have allowed nothing for the wear and tear for machinery?—A. No; I have allowed 16 cents for taxes. That is the only thing I allowed, except just what you have to pay out.

Q. I would like to know something about the condition of the farmer who actually grows his wheat. This represents in the annual wheat crop alone a profit of \$250 a year clear of all expenses, not allowing anything for wear and tear of machinery, loss of horseflesh, and interest upon his land, or anything of that kind. Have you made allowance for the help rendered him by his family?—A. Oh, no. It is giving good wages for working the farm and putting in the crop; just what you would pay if you were hiring it done.

Q. Exactly. What besides the wheat crop does the farmer raise?—A. He raises oats and barley for his own use, and corn to sell. In the southern part of the State

they raise a great deal of corn to sell, and they have poultry and cows and raise some few cattle; but I am speaking now of the little farmer who lives on a small wheat farm.

Q. (By Mr. LITCHMAN.) Do you notice any tendency to a diversification of crops?—A. Yes; there has been much for the last ten years.

Q. Growing more and more so?—A. Yes; I do not know but what they are growing just as much wheat, but they are getting more cattle and growing more corn.

Q. (By Senator KYLE.) Is it your observation that the more wheat a man grows the poorer he gets, as is testified by two or three witnesses?—A. No, no. I can cite many farmers in Brown County, who have attended strictly to their farm and are what we call thrifty men, who have added to their farms more land, and have done it by raising wheat; but these men that I speak of have grown a great deal more wheat than the average. They are the ones who do good farming and raise large crops, while the average is brought down by the shiftless farmer.

Q. In other words, there are a great many farmers throughout your section who almost every year produce 20 bushels to the acre?—A. Yes; or at least this average.

Q. And some of them get as high as even 25 or 35 bushels?—A. Yes.

Q. What do you mean by shiftless farming?—A. The shiftless farmer is one who will put in his crop on the stubble, without even pulverizing it, and not plowing it once in 5 or 6 years.

Q. Simply dragging it in?—A. Dragging it in or scratching it in on the old stubble. Then the field will grow up partly to weeds, and in the fall he will perhaps harvest half of the acreage, and perhaps not any of it. That kind of farming is what cuts down the average.

Q. What percentage of the farming in the Dakotas is carried on in that manner?—A. Ten years ago 20 or 30 per cent, but those farmers have gone now.

Q. (By Mr. LITCHMAN.) The land has passed into the hands of the more thrifty class?—A. Yes; and there is less of it every year. In fact, those same persons are farming better every year; they have more experience.

Q. (By Senator KYLE.) That kind of farming still has a very material effect in depreciating the average?—A. Yes; and another thing that has a great deal to do with reducing the average is that a great deal of the land is owned by mortgage companies, and this is rented on shares, and the man who puts in a crop on another man's land never does it half as well as on his own land.

Q. (By Mr. LITCHMAN.) You say "owned by mortgage companies." How does the land get into their possession?—A. By foreclosure of mortgages.

Q. Do you know of instances where the original farmers have become tenant farmers by that process?—A. Many of them.

Q. (By Mr. FARQUHAR.) Are these native Americans—these shiftless and thriftless farmers?—A. As many Americans as foreigners.

Q. Were they raised as farmers?—A. No; they are men who have come in from other States and taken up the farm land; some of them never were farmers.

Q. (By Senator KYLE.) Used to be designated by the term "stiff-hat" farmers?—A. Yes; or "sidewalk" farmers.

Q. (By Mr. LITCHMAN.) How large a proportion of this land has gone into the hands of mortgage companies?—A. I should think a third of the land in our section of the country.

Q. Will that estimate apply generally to South Dakota, or only to your immediate section?—A. It will apply to the north half of South Dakota.

Q. Is one-sixth of the land of South Dakota owned by mortgage companies?—A. Yes.

Q. (By Senator KYLE.) You might go a little more into detail, and state how a man settling first on his claim mortgaged it and then abandoned it.—A. I will illustrate by saying that a good many farmers who had filed on a quarter section of land and then possibly had taken up a preemption, and of course got the title to this from the Government, undertook to extend their farms and purchased other lands by giving a mortgage on all they had, and during the time of the droughts and the low prices of wheat they had to lose some of their farms and so let one or two of them go on the mortgage. A good many of them still rent these farms.

Q. (By Mr. LITCHMAN.) Now, is there any opportunity for a person to purchase from these mortgage companies?—A. Yes; they are all on the market. They are all listed with real estate men in Aberdeen and other towns and for sale at reasonable prices, and are being purchased sometimes, and quite often, by those who lost them.

Q. Is there any particular section of the country at large represented by these mortgage companies?—A. I think they are largely in New England, New York, and New Jersey.

Q. Then there is no disposition on the part of those companies to hold these lands?—A. No; they are all for sale.

Q. (By Senator KYLE.) Is it not true, also, that a great many settlers come in and prove up on land, make a mortgage to help prove up, and then desert the country?—A. Yes; they get as large a mortgage as possible and immediately desert and leave the land.

Q. (By Mr. FARQUHAR.) Did not a great many preempt and prove up so as to make a mortgage and get as much as they could out of the preemption?—A. Yes.

Q. What is the proportion, should you say?—A. I do not think I could guess.

Q. Was not the practice quite universal a few years ago?—A. It was, from 1883 to 1886, the time of the early settling of that part of the country. Many young men and many young ladies, not of course under age, came there and lived the 6 months, or pretended to live on the claims, and got mortgages on them, and left and never came back. They never intended to live on them or own them.

Q. (By Mr. LITCHMAN.) Did the Lombard Investment Company have any investments in your country?—A. The Lombard Company had millions there in the eighties.

Q. (By Senator KYLE.) Is it not also a fact that in the earlier days the farmers did not know how to handle their soil and therefore frequently made a failure?—A. Yes; they have learned by experience and understand the soil a good deal better.

Q. (By Mr. FARQUHAR.) Is there an advance in the condition of the farmer, an enlargement of his property, and increased satisfaction with farming?—A. The condition of the farmer has advanced every year for 4 or 5 or, I might say, 6 years, and is advancing now. The condition of the farmer is very good.

Q. (By Senator KYLE.) Is it not true that 10 years ago it was quite the custom for the farmer to put all his eggs into one basket, so to speak?—A. Yes.

Q. And devote all his time simply to grain raising?—A. Yes; and, I might say, 5 or 6 years ago many farmers packed up bag and baggage, as you might say, and went into the Province of Winnipeg and the northwestern Canadian possessions; but I think nearly all of them have come back again; they are satisfied with the country, and perfectly satisfied to remain where they are.

Q. (By Mr. LITCHMAN.) What do you say as to the grain-inspection laws of your State?—A. We have no inspection laws in South Dakota. The grain is inspected according to the laws of Minnesota, and that State has an inspection board. The chief inspector is appointed by the governor.

Q. How do these laws protect the farmers?—A. Well, the grading of No. 1 wheat is according to its weight and the amount of hard wheat.

Q. Perhaps you might specify now about No. 2 and No. 3—the manner in which the grain is separated into those grades.—A. No. 1 must weigh 57 pounds to the bushel and contain a good portion of hard wheat in it. No. 2 must weigh 53 pounds—between 56 and 57 pounds. No. 3 must weigh 54 pounds. This is spring wheat. We have no winter wheat. Then the other grades are according to conditions.

Q. Who inspects the farmers' grain at the initial point?—A. The buyer.

Q. How long has this custom of inspection existed?—A. Since I have had any record of it; 10 or 12 years.

Q. The farmer is compelled to accept the grading made by that inspection?—A. You might say yes.

Q. What recourse has he got if he is dissatisfied?—A. He can go to the other elevators.

Q. Is there a combine among the elevators?—A. No.

Q. You say, "the other elevators;" what are the other elevators, please?—A. In Brown County we have operating 12, what you might call elevator companies, whose terminals and headquarters are in Minneapolis.

Q. Can you give the names of the leading ones?—A. Yes. They are the Empire Elevator Company, the George C. Bagley Elevator Company, the Crown Elevator Company, the J. F. Whalen Elevator Company, the Victoria Elevator Company, the G. W. Van Dusen Elevator Company, the Marfield Elevator Company, the Atlas Elevator Company, etc.

Q. Do these elevator companies operate throughout all this section of the country, so far as you are aware?—A. Yes.

Q. Do they substantially cover the whole of the northern part of South Dakota?—A. Yes.

Q. If these elevators have an understanding, and the price is fixed at one elevator, that price governs for the whole number, does it not?—A. Yes.

Q. In case the farmer ships his own grain, who grades at the terminal point?—A. The inspector at Minneapolis—the State inspector.

Q. And he is not in any way connected with the elevator people?—A. No; he is appointed by the governor.

Q. (By Senator KYLE.) Explain that point more in detail; tell how he inspects.—A. On the arrival of the wheat the agents of the inspector go along the train,

break the seal, and open the doors, and they have a long stick that has six or eight little tin boxes on it, or little holes in the stick and little tin covers, and they run this down into the grain clear to the bottom of the wheat, and then they turn a little knob and these little boxes in the stick fill. They then draw it up and open the little boxes, and by looking at them they can tell whether the shippers have put a lot of bad wheat at the bottom or in the middle. If the wheat looks all alike as it passes under their eye they throw it into a box or bag. Then they have a weight test, a little copper kettle, as it is called, and they put the wheat in that and weigh it, marking on the card if it is No. 1 or No. 2, and if it is dirty. Of course they can tell that with their eye. If it is very dirty they take a pound off for dirt; if not very dirty, half a pound.

Q. (By Mr. LITCHMAN.) You say the State inspector makes the grade at the terminal point in case of shipment by the farmer. If the farmer is not satisfied with that grade, what recourse has he?—A. His commission man can call for a reinspection. Then the inspectors go and perhaps take a little more pains with it. That is final.

Q. Are the grains ever mixed at the terminal points in order to raise the grade of the poorest quality?—A. I do not know personally, but I think that is a way the elevator men have of making their money, because from personal observation, and knowing the expenses of the elevators and of operating one, I do not see how they can make very much money in the actual buying of wheat at the initial points.

Q. Do you know if they are thus mixed at the initial point by the buyer?—A. Not very much; there is no chance of mixing at the initial point.

Q. Can you tell what latitude is given to the grader? Is it left to his own personal discretion?—A. No; I do not know anything about that.

Q. Does it not really come down to a matter of judgment on the part of the employee?—A. Entirely.

Q. Now, if he is desiring to please his employer, would he not rather side with him against the farmer?—A. Yes; I think he would.

Q. If the elevator employee desires to please the owners of the elevator, the grading would be apt to be in their favor rather than in favor of the original seller of the grain, would it not?—A. Yes, it would naturally seem so; but it is not true—it may be strange—but the buyers try to please the farmers, because they want to get the most of the wheat. It is invariably the case that they try to please the farmer, and I have known of buyers being discharged by the elevator company because they favored the farmer too much.

Q. Perhaps it may be proper there to ask whether these thrifty farmers, to whom you referred a while ago, acquire a reputation by reason of their thrift for raising better grain than the usual grain, or does that come out in the inspection as to the grade of the grain?—A. They get a better price at the initial station. No elevator company and no buyer is bound to these prices. They invariably pay a cent more and sometimes a cent and a half more for a good quality of wheat than they will perhaps pay to a man who has a poorer quality.

Q. You say you think there is no such thing as an elevator combine in your section?—A. I know there is not.

Q. Is there any consultation as to the fixing of the prices outside of this consultation or arrangement that you have referred to already at Minneapolis?—A. Only that the elevator people agree that they will buy on about a 3 cent margin.

Q. What railroad systems operate through that section of the country?—A. The Chicago, Milwaukee and St. Paul, the Chicago and Northwestern, the Great Northern, the Northern Pacific, and the "Soo" Line.

Q. Do these elevator companies operate over all these lines, or does each elevator company select a different line of transportation?—A. You might say the Empire, the Bagley, the Crown, the Whalen, and the Victoria all operate on the Milwaukee system, with the exception that the Bagley and the Empire operate on the Soo Road. The Van Dusen and the Marfield and the Atlas operate entirely on the Northwestern.

Q. Is there any farming-out of territory among these elevators, so far as you know?—A. No. On the Milwaukee system, at every station there are from 3 to 5 elevators owned by different companies.

Q. Are the farmers compelled to patronize one or the other of these elevator companies?—A. No; they can have a car and ship as they wish.

Q. Do they always get the same consideration from the railroad company that the elevator companies receive?—A. Yes. I do not think you can find a farmer in Brown County who for 5 or 8 years has complained that he could not get a car as promptly as the elevator could.

Q. Do all these companies pay the card price that is fixed at Minneapolis, to which you have already referred?—A. Sometimes they vary from it. I know that

at 5 important stations, one of them Aberdeen, during the whole of the last year, 2 cents above the card price for the entire crop was paid.

Q. Was that due to some special reason?—A. It was due to the fact that the quality of the wheat around those stations was very much better than that at other stations, and they all wanted it.

Q. The farmers have independent elevators in some cases?—A. At nearly every station in Brown County is an independent elevator or flat house owned and operated by independent buyers.

Q. So far as you know, you think there is no obstruction placed in the way of the successful operation and management of these independent elevators?—A. No.

Q. You said that this price card was sent from Minneapolis to some one person. Have you any objection to telling who that person is in your locality?—A. No; I am the person and have been for the last 10 years, and I furnish the prices to the independents and the mills and the line companies all alike. Nobody is prohibited from having the price furnished.

Q. When you have received that price, what is the process of distributing the information?—A. If the advice I get from Minneapolis is to distribute the price by wire, I immediately send by telegraph and telephone to the different stations or elevators. These messages are followed on the evening mails by the card. Of course the telegram is either to reduce or to advance the price 1 cent, or more, as the case may be.

Q. Are there any individual shippers or grain men independent of the elevators?—A. The arrangement is that I shall send this information to one of the buyers at each station, and that one is agreed upon by all the others at the station. That is done to save the expense of many telegrams. That buyer immediately notifies all the others.

Q. Outside of these are there any individual shippers of grain that are not owners or controllers of elevators?—A. Yes.

Q. What is their means of obtaining the card price?—A. They get it in just the same way. They can obtain it by paying their share of expense at that station.

Q. So far as you know, is there any disposition on the part of the elevator companies to "bear" the price at certain seasons of the year? Have you seen any evidence of that tendency?—A. No.

Q. Do you think that is controlled at the terminal point, at Minneapolis?—A. I think it is controlled by this committee, and I think that the understanding of the committee is that the margin shall be just about the same the year round.

Q. What percentage of the farmers are compelled to sell the grain within 3 or 4 months of the threshing time?—A. A large percentage.

Q. Sixty per cent?—A. Yes, I should think so. Not more than that. There are a good many farmers who do not have facilities for storing it to amount to anything, and they haul directly to the elevators.

Q. Is this speedy disposal due to the lack of storage room or to their pecuniary circumstances?—A. Both.

Q. Then the card price, as a matter of course, would be lower generally during that 3 or 4 months, would it not?—A. I presume it might be; I think the average shows that.

Q. Will you go, now, into the privileges given to the farmers' elevators in your section?—A. If a number of farmers wish to erect an elevator, they apply to the railroad company. They pay \$5 ground rent, just the same as the line elevators do, and they put up their elevator, and to all appearances operate it just the same as the line companies operate their elevators.

Q. So far as you know, is there any obstruction placed in the way of these independent companies by the railroads?—A. I do not know of any.

Q. Is there a law in your State compelling railroads to give these facilities to the independent elevators?—A. Yes.

Q. Have you any idea how long that law has been in existence?—A. I think it has been 6 or 8 years.

Q. Was not that law the result of the indisposition on the part of the railroads to give these facilities?—A. Yes.

Q. Then it is fair to presume there was at one time opposition on the part of the railroads?—A. Yes.

Q. If the railroads had the disposition to favor the line elevators as against the independents, the inclination still exists if the opportunity does not?—A. Yes; I should think so.

Q. And that could be accomplished by discriminations and rebates on freights as well as by a famine of cars and other devices known to the internal machinery of railroad management?—A. There is a good deal of talk that some of the line

break the seal, and open the doors, and they have a long stick that has six or eight little tin boxes on it, or little holes in the stick and little tin covers, and they run this down into the grain clear to the bottom of the wheat, and then they turn a little knob and these little boxes in the stick fill. They then draw it up and open the little boxes, and by looking at them they can tell whether the shippers have put a lot of bad wheat at the bottom or in the middle. If the wheat looks all alike as it passes under their eye they throw it into a box or bag. Then they have a weight test, a little copper kettle, as it is called, and they put the wheat in that and weigh it, marking on the card if it is No. 1 or No. 2, and if it is dirty. Of course they can tell that with their eye. If it is very dirty they take a pound off for dirt; if not very dirty, half a pound.

Q. (By Mr. LITCHMAN.) You say the State inspector makes the grade at the terminal point in case of shipment by the farmer. If the farmer is not satisfied with that grade, what recourse has he?—A. His commission man can call for a reinspection. Then the inspectors go and perhaps take a little more pains with it. That is final.

Q. Are the grains ever mixed at the terminal points in order to raise the grade of the poorest quality?—A. I do not know personally, but I think that is a way the elevator men have of making their money, because from personal observation, and knowing the expenses of the elevators and of operating one, I do not see how they can make very much money in the actual buying of wheat at the initial points.

Q. Do you know if they are thus mixed at the initial point by the buyer?—A. Not very much; there is no chance of mixing at the initial point.

Q. Can you tell what latitude is given to the grader? Is it left to his own personal discretion?—A. No; I do not know anything about that.

Q. Does it not really come down to a matter of judgment on the part of the employee?—A. Entirely.

Q. Now, if he is desiring to please his employer, would he not rather side with him against the farmer?—A. Yes; I think he would.

Q. If the elevator employee desires to please the owners of the elevator, the grading would be apt to be in their favor rather than in favor of the original seller of the grain, would it not?—A. Yes, it would naturally seem so; but it is not true—it may be strange—but the buyers try to please the farmers, because they want to get the most of the wheat. It is invariably the case that they try to please the farmer, and I have known of buyers being discharged by the elevator company because they favored the farmer too much.

Q. Perhaps it may be proper there to ask whether these thrifty farmers, to whom you referred a while ago, acquire a reputation by reason of their thrift for raising better grain than the usual grain, or does that come out in the inspection as to the grade of the grain?—A. They get a better price at the initial station. No elevator company and no buyer is bound to these prices. They invariably pay a cent more and sometimes a cent and a half more for a good quality of wheat than they will perhaps pay to a man who has a poorer quality.

Q. You say you think there is no such thing as an elevator combine in your section?—A. I know there is not.

Q. Is there any consultation as to the fixing of the prices outside of this consultation or arrangement that you have referred to already at Minneapolis?—A. Only that the elevator people agree that they will buy on about a 3 cent margin.

Q. What railroad systems operate through that section of the country?—A. The Chicago, Milwaukee and St. Paul, the Chicago and Northwestern, the Great Northern, the Northern Pacific, and the "Soo" Line.

Q. Do these elevator companies operate over all these lines, or does each elevator company select a different line of transportation?—A. You might say the Empire, the Bagley, the Crown, the Whalen, and the Victoria all operate on the Milwaukee system, with the exception that the Bagley and the Empire operate on the Soo Road. The Van Dusen and the Marfield and the Atlas operate entirely on the Northwestern.

Q. Is there any farming-out of territory among these elevators, so far as you know?—A. No. On the Milwaukee system, at every station there are from 3 to 5 elevators owned by different companies.

Q. Are the farmers compelled to patronize one or the other of these elevator companies?—A. No; they can have a car and ship as they wish.

Q. Do they always get the same consideration from the railroad company that the elevator companies receive?—A. Yes. I do not think you can find a farmer in Brown County who for 5 or 8 years has complained that he could not get a car as promptly as the elevator could.

Q. Do all these companies pay the card price that is fixed at Minneapolis, to which you have already referred?—A. Sometimes they vary from it. I know that

will investigate some of these shipments you will find that the shipment happened to be made on a rising market. Perhaps during the three days while the car was in transit the market advanced 2 or 3 cents. The shipper, of course, also got the margin which the elevators take, and got 5 or 6 cents more than the card price, and if he had a particularly good grade of wheat and all of one kind he would get a cent higher, or possibly a cent and a half more, because some of them might want it for mixing purposes. But these instances are always reported in the papers. If somebody else shipped, or the same person, and happened to strike a falling market that incident would not get into the papers."

Q. (By Mr. FARQUHAR.) Is the percentage of your high-grade wheat large enough to make a difference to these independent shippers, or does the average of your wheat run into the ordinary grades?—A. The ordinary grades.

Q. (By Mr. A. L. HARRIS.) Have you any further statement to make?—A. I had prepared some figures on the cost of running elevators. Some of the questions, of course, have already been asked and answered, but I will give the statement about as I had intended to do.

Brown County, S. Dak., is 36 miles wide and 48 miles long. The railway system in Brown County and the number of elevators at the stations is just about the same as throughout the three States of South Dakota, North Dakota, and Minnesota. I presume it is an average for the three States. There are in this county 20 railway stations where wheat is bought and shipped. At these stations are 45 elevators, having a capacity of 12,000 to 15,000 bushels each, and 12 flat houses with a capacity of 3,000 to 5,000 each, and there are 3 flouring mills with large elevators attached. At two or three of the stations are special loading platforms. These platforms are erected for the farmers, and to them you drive up just as you drive to an elevator and unload into the car. At other stations they must load from the regular depot platform, or if the ground is level they drive right up to the side of the grain door. Thirty of these houses are owned and operated by what is called the line companies, and there are 12 different elevator companies operating in the county having headquarters at Minneapolis.

Q. What do you mean by line companies?—A. I speak of a line company as the regular elevator companies who have headquarters outside of the State. We call them line companies. Twenty of the houses are owned and operated by independent parties. If the crop is large, nearly all of these houses are opened; if the crop is only fair, not so many of them are opened, and if the crop is poor, as it is this year, only about half of the houses are opened. In 1899 nearly all were opened, while in 1900 only a little over one-half of them were opened. The elevators each will handle in a good season about 50,000 bushels of wheat during the 12 months. In talking with several of the elevator men about this estimate I had made, they all said it was too much; they said that several years ago, when there were not so many elevators, they would average that much, but not now. Handling this amount during 12 months, the labor and expense attached to the station will amount to 1½ cents a bushel. This is figuring the pay of the man who operates the elevator and buys the wheat, the expense of elevating, and in a busy season a helper that he has to have.

If an elevator company has a line of houses there should be added to the expense account the cost of maintaining an office at the terminal point, traveling expenses, insurance and taxes on the elevator, and interest on a certain amount of money needed to operate such an elevator. This is without making allowance for depreciation and insurance on grain that is necessarily on hand and can not be shipped out, which will add three-fourths of a cent per bushel to the elevator expense, making a total cost per bushel of 2½ cents. By grain necessarily on hand I mean that an elevator must have quite a little grain on hand all the time, because he may have 400 bushels of No. 1 wheat, 400 bushels of No. 2, and 400 of No. 3—not enough of either one for a car, as a car carries about 700 bushels. If the same elevator handles 65,000 bushels, the expense should be figured a quarter of a cent less, or at the rate of 2 cents a bushel. If it handles 80,000 bushels the expense would be about 1½ cents; if 100,000 bushels, about 1¼ cents. If, as in a poor year, the house only handles 35,000 bushels, the expense will be increased a quarter of a cent. Very few houses handle 100,000 bushels. When a crop is light, and the amount to be handled is consequently small, the expenses can not be reduced in proportion, because they have to pay just as much for a man, and if they elevate with a horse they have to keep the horse just the same.

Q. (By Mr. C. J. HARRIS.) Do these elevators clean wheat?—A. There are only two elevators among all these in Brown County that have cleaners. They are at Aberdeen.

"I do not know that this is important, but elevator companies always keep on hand wheat to cover storage tickets outstanding; if not at the same elevator where the tickets were issued, at some other near-by point. A good many think that all the

stored wheat is shipped to the terminal points, but this is not the fact with elevator companies; they aim to keep it somewhere on their line.

Q. (By Mr. A. L. HARRIS.) Do your elevators accept wheat on storage?—A. Yes; it is quite a considerable source of profit to the elevator.

Q. What are the storage rates?—A. Storage rates for the first 15 days are free. They make a storage rate for 3 months and 15 days of 3 cents; after that the rate is one half cent per month for the next 3 months, which would make the rate for 6 months and 15 days 4½ cents. For 9 months and 15 days it would be 6 cents. They store wheat all the year round, and sometimes for 2 or 3 years.

Q. There is no selling point in the year?—A. Not necessarily; I know of wheat in some of the elevators on which tickets are out that are 2 or 3 years old.

Q. (By Mr. FARQUHAR.) You do not have to store wheat in a year of poor crop and low grade?—A. No.

Q. Your low grade of wheat seeks a market as soon as possible?—A. Yes.

Q. (By Mr. A. L. HARRIS.) What is the advantage of shipping a low grade of wheat?—A. The farmer has got to take his chances with the inspectors at Minneapolis. I do not know as I know of any instances where farmers have attempted to ship their low-grade wheat; they put that right on the market. While there is a card price for No. 3 wheat at the present time—it is 10 cents below No. 2—some farmers will get 5 or 6 cents higher than the card price, because while it grades No. 3 it is a pretty good quality of wheat. That is true this year. Ordinarily the prices of Nos. 1, 2, and 3 are not far apart.

Q. From the standpoint of a business man and as a farmer, what is the best time, in your experience, to sell wheat?—A. Immediately after threshing; and I think the experience of every farmer will be that he gets the best price immediately if he can get to the market first.

Q. What price should he receive 6 or 8 months thereafter if he keeps his wheat?—A. He ought to get 3 or 4 cen's advance. There is a loss by mice and rats, and then there is the shrinkage in the warehouse or farm granary.

Q. There is some expense in putting it away and taking it out?—A. Yes. When I speak of rats, I refer to the rats in his own elevator. Of course, he gets a ticket when the grain is stored in another elevator, and there is then no loss of wheat to him.

Q. (By Mr. RIPLEY.) Does the fact that he gets a ticket from the elevator mean that his particular grain is held, or its equivalent?—A. The equivalent.

Q. So it is at the option of the elevator man to hold that particular wheat or simply substitute other wheat for it?—A. It is very seldom that a farmer asks for his wheat. The elevator companies charge 2½ cents if the owner calls for his wheat. That is what they call delivery.

Q. You say it costs the farmer 2½ cents to get the wheat out in any other way except for shipment along the line of the road?—A. Yes; they call that a storage fee. If you take it out you pay 2½ cents.

Q. Can a farmer draw against that storage ticket? Will the local banks accept a storage ticket?—A. Yes; they will loan within 5 or 10 cents of the price of the wheat. If wheat is 50 cents, they will loan 40 cents if there is a steady market.

Q. (By Mr. A. L. HARRIS.) What are the wages for farm hands?—A. Farm wages in the country by the year, with board and lodging, are from \$200 to \$310. They are about 20 per cent higher than they were 4 years ago. By the month they are about \$20 for the 8 summer months, and from \$8 to \$10 for the 4 winter months. They are about \$3 to \$3.50 for harvest and about \$1.50 for the haying season by the day. All these wages include board, and the hours, like all farm hours, are long.

Q. Have you anything that you desire to state on your own motion?—A. There is one thing that the farmers complain of, and I think it is a just complaint, and that is that the freight rates between points in South Dakota to Minneapolis are a little too high in proportion to the rates for greater distances. For instance, from Aberdeen the rate to Minneapolis is 10.2 cents per bushel, while to Chicago it is 16.2; from Aberdeen to Minneapolis the distance is 280 miles, and from Aberdeen to Chicago it is 700 miles. The rate for the last 400 miles is 6 cents, and for the first 300 miles is 10.2.

Q. (By Mr. FARQUHAR.) Does the car from Aberdeen go to Chicago without elevator or change?—A. Never.

Q. Where is your change of cars?—A. Our wheat is nearly all unloaded and sold at Minneapolis, because the price there is about equal to the Chicago price. A farmer never ships through to Chicago, because he would lose 2 or 3 cents per bushel.

Q. What is the advantage to the railroad company in making the discrimination in favor of Chicago and against Minneapolis?—A. The rate on wheat is 2

cents per hundred between Minneapolis and Chicago; the rate on flour, I think, is 15 cents per hundred.

Q. (By Mr. RIPLEY.) What is the rate on wheat from Aberdeen to Duluth?—A. The rate to Chicago is 27 cents per hundred weight, or 16½ cents a bushel; to Duluth it is 20 cents a hundred, or 12 cents a bushel; to Minneapolis it is 17 cents per hundred, or 10½ cents per bushel. It is 1.8 cents to Duluth more than to Minneapolis.

Q. Does any of the wheat from your section go to Duluth direct?—A. Yes.

Q. Not for milling, as at Minneapolis, but usually for transshipment by the lakes?—A. Yes.

Q. And for export?—A. And for export; yes.

Q. Is it possible to bill through to either a foreign port or to New York from Aberdeen, or must your bill of lading read to Duluth?—A. I think I could ship a car of wheat to New York.

Q. By way of Duluth?—A. I guess the charges would eat it all up. I do not know of any instance of the kind, because the difference in price between Minneapolis and New York is very much less than the freight.

Q. Is not that true of Chicago?—A. It is true of Chicago. The price in Minneapolis is more than the price in Chicago, taking the freight into consideration.

Q. Is that due to local consumption by the mills in Minneapolis?—A. Yes. We never ship wheat to Chicago or Milwaukee, because Minneapolis and Duluth are much better markets, and we would lose 2 or 3 cents by shipping to Chicago.

Q. (By Mr. FARQUHAR.) What have been the rates of interest on mortgages within the last 10 years in your section?—A. Ten years ago it was easy to get a 10 per cent farm mortgage; now it is hard work to get a 6 per cent farm mortgage.

Q. Have there been many transfers from these loan companies and land associations of lapsed farms that were foreclosed?—A. Mr. Lincoln, of the firm of Lincoln & Boyd, of Aberdeen, told me a few days ago, after he got out his January statement, that he had sold 600 farms during the past year. And he told me that his foreclosure account, while several years ago it would run \$3,000 or \$4,000, this year was less than \$300—that is, profit on foreclosures. They are practically foreclosing none now.

Q. What does that land sell for now? What is the average price of that class of farms?—A. They will sell for from \$600 to \$1,000, while some that have been well farmed and well taken care of will sell for twice as much.

Q. Are many of your good farms changing hands now?—A. Yes. I sold a farm last September, 4 miles north of Aberdeen, of 320 acres, with very poor buildings, for \$3,500, that 2 years ago I tried to sell for \$2,000. That is a fair illustration.

Q. So farm lands have appreciated in your section?—A. In the last 3 years they have, considerably.

Q. How great is the appreciation?—A. It has been 60 per cent.

Q. What class of men are buying there now? Are they practical farmers or young men of your section?—A. Mostly farmers buying for their sons. Now and then a farmer comes in from another State and buys a farm.

Q. In your section are you able to mature Indian corn?—A. We mature a small grade of corn. It is smaller than the corn in Iowa, and we mature it nearly every year.

Q. Are you successful with it?—A. Farmers are increasing their acreage every year.

Q. What is the reason you can not go into winter-wheat raising?—A. It has been tried several times, but it kills out in the winter.

Q. Is the killing due to the seasonal changes, to your damp and frost?—A. Our ground dries out. Unless it has a good deal of rain in the fall it will freeze out dry on the top. I know of several farmers who have tried the winter wheat, but it is not a success. It does not come up in the spring.

(Testimony closed.)

WASHINGTON, D. C., January 22, 1901.

TESTIMONY OF DR. D. E. SALMON,

Chief of the Bureau of Animal Industry, United States Department of Agriculture.

The commission met at 10.45 a. m., Mr. Farquhar presiding. At that time Dr. D. E. Salmon, Chief of the Bureau of Animal Industry, United States Department of Agriculture, appeared as a witness, and, being duly sworn, testified as follows:

Q. (By Mr. FARQUHAR.) Give your name and address and official position in the Agricultural Department.—A. D. E. Salmon, Chief of the Bureau of Animal Industry, Department of Agriculture.

Q. (By Mr. A. L. HARRIS.) You may state how long you have been connected with the Bureau of Animal Industry.—A. I have been connected with it since its formation, in 1884. I was appointed chief at that time.

Q. Have you a paper which you desire to present to the commission?—A. Yes; I have prepared a statement covering the work in which I am engaged. I have first given a tabular statement to give an idea as to the work dividing it according to the objects of the Bureau of Animal Industry. I will put that in first, in order to give the plan of what I have to say, because I have made the statement as brief as possible. It is as follows:

THE WORK OF THE BUREAU OF ANIMAL INDUSTRY.

- A.—Control of contagious diseases of animals in the United States.
 - 1. Eradication of pleuropneumonia (completed).
 - 2. Control of Texas fever.
 - 3. Control of sheep scab.
- B.—To prevent importation of contagion.
 - 1. Quarantine of Atlantic ports.
 - 2. Inspection and quarantine along Mexican and Canadian borders.
 - 3. Tuberculin tests of cattle in Great Britain and Canada.
- C.—To prevent exportation of contagion.
 - 1. Inspection of exported live stock.
- D.—Meat inspection.
 - 1. Ante and post mortem inspection of interstate and export meat.
 - 2. Trichinæ inspection.
- E.—Investigation of diseases and remedies.
 - 1. Texas fever.
 - 2. Hog cholera.
 - 3. Sheep-scab dips.
 - 4. Tuberculosis.
 - 5. Rabies.
 - 6. Other contagious and noncontagious diseases, so far as facilities permit.
- F.—Cooperation to prevent disease.
 - 1. Supplying tuberculin to State authorities.
 - 2. Supplying mallein to State authorities and to War Department.
 - 3. Blackleg vaccine.
 - 4. Enforcing Texas-fever quarantine line.
- G.—To aid exports:
 - 1. Trichinæ inspection.
 - 2. Inspection of live animals for export.
 - 3. General inspection of meat for export.
 - 4. Inspection and control of cattle fittings on steamers carrying animals for export.
 - 5. Experimental shipments of butter, cheese, and eggs.
- H.—Collection of information:
 - 1. As to diseases.
 - 2. As to breeds, breeding, and feeding.
 - 3. As to the dairy industry.
 - 4. As to the condition of the animal industry.

SUGGESTIONS AS TO FEDERAL LEGISLATION.

- 1. Requiring cleaning and disinfection of stock cars and stock yards when necessary.
- 2. Authorizing Department of Agriculture to require proper disposition of condemned meat.
- 3. More comprehensive penalty clause for shipping condemned meat.
- 4. To make regulations prohibiting shipment of uninspected meat from State to State and to foreign countries.
- 5. Authorizing inspection and certification of pure, high-grade dairy products for export.
- 6. Making transportation companies liable for violation of law when in hands of receiver.

SUGGESTIONS AS TO WHAT IS NEEDED IN THE WAY OF STATE WORK.

- 1. The thorough control of glanders, tuberculosis, and rabies, and the eradication of trichinæ.
- 2. The destruction of the Texas fever tick.

3. Measures to insure the wholesomeness of the milk supply.
 4. Measures to guard the public against impure, adulterated, or renovated butter and filled or adulterated cheese.
 5. Better local inspection of meats and the proper disposition of diseased meats.
- The witness continued to read as follows:
- "It appears that I can best present the facts within my knowledge by a statement of the work of the Bureau of Animal Industry, in which I have been engaged for the past 16 years. I present herewith a summary in tabular form of this work. It is naturally divided into eight sections.

A.

"The first section has reference to the control of contagious diseases of animals in the United States.

"1. The disease more particularly in view at the time the Bureau was established was contagious pleuropneumonia of cattle, which was causing much anxiety among the stock raisers of the United States and had also interfered with our exports of live cattle. This disease was stamped out by cooperation between the Bureau of Animal Industry and the authorities of the various interested States. The work was completed several years ago.

"2. The disease next in importance, and to which attention was early directed, is Texas fever. The accompanying map shows the quarantine line which has been established to prevent the spread of this disease."

"The portion of the country south of this line is permanently infected with the Texas fever contagion. While the cattle in this area do not suffer to any considerable extent from the disease, they carry the contagion with them when they are taken to other sections of the country, and in that manner produce fatal outbreaks. The quarantine does not prevent the shipment of cattle for slaughter at any season of the year providing this is by rail and that proper precautions are taken when the animals are unloaded. The result of this inspection has been to almost entirely prevent outbreaks of Texas fever in the noninfected territory (that is, the territory north of that line), and also to prevent its development among cattle en route to European markets. Cattle to be sold for grazing are allowed to be shipped from the infected district during the months of November and December without restriction.

"3. The third disease which the Bureau has undertaken to control is sheep scab. This disease, which is easily cured, has not been understood by sheep owners, and has been allowed to spread until it has become one of the greatest obstacles to the prosperity of the sheep industry. Inspectors have been recently stationed in the Western States and Territories to prevent the shipment of diseased animals, and where disease is found, to supervise the dipping of the sheep, so that they may be safely sent to market. Inspection for this disease is also maintained in the principal stock yards, and dipping plants have been established so that diseased sheep may be treated before they are forwarded to other States.

"To indicate the amount of work done in this line I would state that during the quarantine season of 1899 the employees of this Bureau inspected and supervised the movement of 1,058,494 cattle, and also supervised the disinfection of 39,663 cars in which such infected cattle had been carried. For the control of sheep scab these inspectors examined 1,801,379 sheep and supervised the dipping of 636,838.

B.

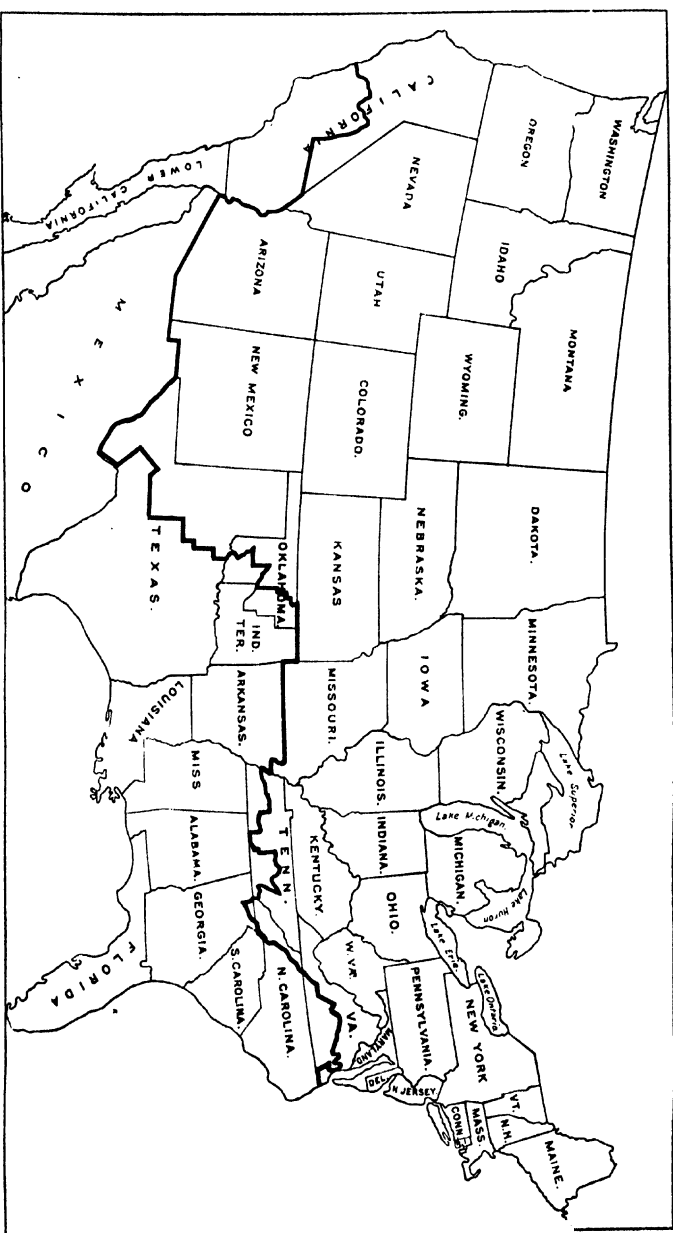

"1. In order to prevent the importation of contagion, animal quarantine stations have been established on the Atlantic coast, one for the port of Boston, one for the port of New York, and one for the port of Baltimore. Cattle from countries where pleuropneumonia has existed are held in quarantine 90 days. Other ruminants and swine are quarantined for 15 days.

"2. Inspection and quarantine stations have also been established along the Mexican and Canadian borders. Animals are only quarantined a sufficient time for inspection, except in cases where they are found diseased.

"3. Tuberculin tests are also required in order to guard against the importation of animals affected with tuberculosis. An inspector has recently been sent to Great Britain to make tuberculin tests there, so that diseased animals may be rejected before shipment. The same action has been taken in regard to Canada."

I would say we do this because unless the animals are tested on the other side or before they come from Canada, we find so many diseased cattle that it is embarrassing to dispose of them. The law under which we are working prohibits the importation of diseased animals, and we are making tests on the other side, very much to the satisfaction of our stock raisers.

BOUNDARY LINE OF THE DISTRICT INFECTED WITH SPLENETIC OR SOUTHERN CATTLE FEVER.
 Reduced from map published by United States Bureau of Animal Industry.

"The animals from Mexico which were inspected during the last fiscal year were 80,329 head of cattle, 9,976 sheep, 44 swine, 4,132 goats, and 3 horses, making a total of 94,484. Those from Canada were 77,693 cattle, 209,373 sheep, 1,886 horses, 1,092 swine, 6 goats, and 1 deer, making a total of 290,051. The animals imported from Europe were 379 cattle, 370 sheep, 2 swine, making a total of 751.

C.

"To prevent the exportation of contagion, horses, cattle, and sheep are inspected before shipment. The cattle are marked in the ear with a numbered tag and a record made of their origin. Horses are also marked with a tag, and certificates are issued as to the healthfulness of cattle and horses. On account of the existence of sheep scab and the general infection of stock yards and cars, it has been impossible up to this time to issue certificates for sheep. During the fiscal year ending June 30, 1900, 305,182 exported cattle were thus inspected, 73,426 sheep, and 37,080 horses.

B.

"Meat inspection has been established at the principal packing houses to guard against the interstate and foreign shipment of diseased meat.

"1. An inspection is made before the animals are slaughtered and again upon the carcasses at the time they are being dressed. The meat which is sound and wholesome is marked for identification and certified to in accordance with the law. In this line of work there were inspected in the last fiscal year 31,737,613 carcasses.

"2. There is also maintained a microscopic inspection of pork for trichinae. This is applied only to pork for export to certain countries which require such an inspection. The greater part of such products goes to Germany and France. The number of pounds of pork microscopically inspected which was exported last year was 55,809,626, the trade last year having greatly declined. In previous years as much as 120,000,000 pounds of such pork have been exported in one year.

E.

"Investigations of contagious diseases and remedies for the same have been conducted since the formation of the Bureau.

"1. One of the principal lines of investigation was with reference to Texas fever, the nature of which was not at all understood at the time these investigations began. All of the mysteries in regard to Texas fever have been cleared up, and we are now able to control it very effectually. Not only is the dissemination of the contagion prevented by the regulations governing the shipment of cattle from the infected district, but by suitable measures the particular species of ticks which cause the disease is being eradicated in many sections and the contagion thus stamped out. It is also possible now to inoculate cattle needed in the Texas fever belt for breeding purposes before they are shipped from the Northern States so that they will resist the fever when exposed to it. There is one other line of experimentation in regard to this disease which has been carried on quite hopefully, but so far without success: that is, the application to the infected cattle of remedies for the destruction of the tick. If these parasites could be destroyed before the cattle leave the infected area, there would be no need of restrictions when such animals go to northern markets. Unfortunately, this tick has been very resistant, and remedies so far discovered which kill it injure the cattle so severely that their use is not practical.

"2. Hog cholera has also been investigated for many years, being one of the most serious animal plagues which exist in the country. While much has been learned in regard to it, and certain measures have been recommended which lessen its ravages somewhat, a practical and successful method of prevention for general use has not been discovered. It is a problem upon which our experts are still working.

"3. In the control of sheep scab it very early became necessary to recommend dips which could be relied upon for curing the disease without injuring the animals or those who performed the dipping. Various investigations were therefore made in this direction, and two standard dips have been adopted for use under the supervision of Bureau inspectors.

"4. A number of investigations have also been made of tuberculosis. This disease has become quite common among dairy and breeding cattle and in swine. In Europe tuberculosis is considered the most serious disease affecting the domesticated animals, and the one which causes the greatest losses. The bureau investigations have been made with the idea of determining, first, the prevalence of the

disease; secondly, the effect of tuberculin when used for its diagnosis, and thirdly, the infectiousness of dairy products, particularly milk and butter.

"5. The occurrence of an outbreak of rabies in the District of Columbia has led to some investigations to determine the extent of this disease in other parts of the country. These investigations show that rabies has become very common in the United States, and that it not only affects dogs, but a large number of horses, cattle, sheep, and swine are bitten and die of it. Many persons are also bitten in the course of a year, a considerable number of whom contract the disease.

"6. Various other diseases which are of importance from time to time have been reported to the Bureau and have been investigated. These investigations are continually in progress and are pressed forward as rapidly as the equipment and force of the Bureau will permit.

F.

"The Bureau is also working to prevent disease by cooperation with State authorities and individual stock owners.

"1. One means of doing this is to supply State authorities with tuberculin to be used in testing animals for tuberculosis. The tuberculin is manufactured in the laboratory of the Bureau and supplied free of expense for official use. It is a great aid to the State authorities in this work.

"2. Mallein, for the detection of glanders in horses, is supplied in the same manner both to State authorities and to the Federal War Department.

"During the past year 33,400 doses of tuberculin were thus supplied, and 10,722 doses of mallein.

"3. The Bureau has also been making vaccine for the disease known as blackleg of cattle. This is supplied directly to cattle owners in the districts affected with this malady. During the past fiscal year 1,076,150 doses of this vaccine were thus made and supplied. The loss of cattle from blackleg in infected herds averages over 10 per cent of the young stock. The vaccine saves all of such losses with the exception of about one-half of 1 per cent. Consequently, if a million doses of this vaccine were actually used by the stock owners, the saving would amount to about 100,000 head.

"4. Where the Texas-fever quarantine line crosses a State or Territory, as in the case of Virginia, North Carolina, Georgia, Tennessee, Oklahoma, Texas, and California, this line is maintained by cooperation between the State authorities and the Bureau of Animal Industry. As the law establishing the Bureau makes the penalty apply to the shipment of animals from one State or Territory to another, the Federal authorities could only make a quarantine line corresponding with the boundary lines of States. This would cause a considerable hardship in many cases where a large section of a State is free from infection, and consequently an effort has been made to place the quarantine line on the boundary of the infected district and to have this line, where it crosses the territory of a State, enforced by the authorities of that State.

G.

"The work of the Bureau to aid exportation of American animals and products may be divided into—

"1. The trichine inspection;

"2. The inspection of live animals for export;

"3. The general inspection of meat for export; to all of which reference has been made.

"4. In addition to this work there is maintained an inspection and control of cattle fittings on steamers carrying animals for European markets. The strength, space, ventilation, width of aisles, etc., are prescribed, also the number of attendants which must be taken to care for the animals en route. The effect of these regulations has been very marked, and has reduced the losses in the ocean carrying trade tremendously. At the time the regulations went into effect the insurance on exported cattle was about 8 per cent of their value. It is now considerably less than 1 per cent; and this difference represents about what has been saved to the exporters by properly controlling this trade.

"5. Experimental shipments of butter, cheese, and eggs have also been made to markets where it was thought desirable to bring these products to the attention of consumers. Much has been done to create a demand for these American products, especially in Great Britain. Experimental shipments are, however, being made to other sections of the world.

H.

"In order to stimulate the various branches of animal industry and to improve prevailing methods, information is collected and distributed, in accordance with the law, in regard to various subjects, the most prominent topics being—

- "1. The nature and treatment of prevailing diseases;
- "2. The characteristics of various breeds of animals, and methods of breeding and feeding;
- "3. The condition of the dairy industry, and information as to improved methods;
- "4. Information as to the general condition of the animal industry.

SUGGESTIONS AS TO FEDERAL LEGISLATION.

"It will be seen from this outline of the work of the Bureau that the Federal Government has gone into this field quite largely, and that what is now needed is not so much an extension of the work to new subjects, as the improvement and perfection of the work already undertaken.

"What I would suggest in the way of Federal legislation is—

"1. Authority for the Secretary of Agriculture to cause the cleaning and disinfection of stock cars and stock yards whenever he considers such action necessary. Owing to the extension of our railroad system, the shipment of animals long distances, both to and from the farms, is common, and the routes of transportation become contaminated with contagion of various kinds, which affects the store stock that is purchased in the stock yards to be taken back to the farms and ranges for grazing and feeding. Hog cholera, sheep scab, glanders, and other diseases are spread in this manner. The authority to cause the cleaning and disinfection of cars and stock yards is not clear, and it is only with considerable difficulty and delay that this is in many cases secured. Such authority would go far toward preventing the dissemination of contagion from one State or Territory to another.

"2. The Department of Agriculture should be given specific authority to require the proper disposition of diseased meat. At present the law authorizes the inspection of meat that is to be shipped from one State to another or to foreign countries and the marking of that which is sound and wholesome, leaving the diseased meat to be disposed of locally as the abattoir managers may desire. If such diseased meat is allowed to pass beyond the authority of the Department inspectors it is impossible to prevent its being shipped to other States or being put upon the market for sale wherever it can be disposed of. It appears to me that if the Federal Government has authority to inspect meat it has also the authority to require the proper disposition of that which is condemned."

I ought to say in further explanation that at present we make an agreement with the abattoir managers that they will dispose of this meat according to our regulations. We have no law which authorizes us to do that, but so far we have not been able to cover the whole country with the inspection, and we simply say, "We will not put an inspector in your abattoir unless you agree to do this." I think there should be some law which would absolutely prevent the selling of condemned meat, for when it gets on the market we have no way of knowing whether it stays in the State where the slaughtering is done or is shipped out. The fact is a short time ago we had a little conflict of authority with the Illinois State people about a steer that was killed that had tuberculosis. Our inspector condemned it and their inspector passed it, and the State commission demanded that we should turn over the carcass to them to be used locally. We asked for some definite evidence that the meat was to be used locally in the State of Illinois, and when they investigated the matter they found it had been sold to a large canning establishment in Chicago, and of course they could not say it was to be used in Illinois. It might be used outside of the State, but that is the way those things go. When you once let loose of diseased meat and it gets out of the inspector's hands it is liable to go anywhere. There is no way of keeping track of it.

(Witness continues to read)

"3. I would also suggest a more comprehensive penalty clause for shipping condemned meat. The following sections were drawn in accordance with this idea:

"SEC. —. That any person, company or corporation, owner or shipper of such products mentioned in section —, failing to so mark such products, or who marks such products falsely, or who falsely marks such products as inspected in accordance with the law, or who falsely brands, claims, or publishes that such products have received inspection according to law, or who stamps, brands, or marks such products with the stamps, brands, or marks of the Bureau of Animal Industry, obtained or used in a fraudulent manner, or otherwise than according

to the rules and regulations of said Bureau, or who shall forge, counterfeit, simulate, imitate, falsely represent, or use without authority, or knowingly and wrongfully alter, deface, or destroy any of the marks, stamps, or other devices provided for in the regulations of the Secretary of Agriculture, of any such carcasses or their products, or who shall forge, counterfeit, simulate, imitate, falsely represent, or use without authority, or knowingly and wrongfully alter, deface, or destroy any certificate or stamp provided in said regulations, shall be deemed guilty of a misdemeanor, and on conviction thereof shall be punished by a fine not exceeding one thousand dollars, or imprisonment not exceeding one year, or by both said punishments, in the discretion of the court."

That is a little more comprehensive than our present penalty clause, and it was drawn up after several years' experience through which we found that some of these slaughterers are very ingenious in evading the law, and a great many of these points were put in after the ways in which they succeeded in getting meat out had been noted.

(Witness continued to read:)

"SEC. —. That it shall be unlawful to transport from one State or Territory or the District of Columbia into any other State or Territory or the District of Columbia, or to deliver for transportation from one State or Territory or the District of Columbia into another State or Territory or the District of Columbia, the carcasses of any cattle, sheep, swine, or other animals, or the food products thereof, which have been examined in accordance with the rules and regulations of the Bureau of Animal Industry, and which on said examination have been condemned by the inspector making the same as unsound or diseased, and so marked. Any violation of the provisions of this section shall be deemed a misdemeanor and punishable by fine not to exceed one thousand dollars.

"SEC. —. That upon an examination of animals, carcasses, or parts of carcasses by the inspectors of the Bureau of Animal Industry, said inspectors shall be authorized to condemn such as are found diseased or unfit for human food according to the rules and regulations of said Bureau, and, if necessary, to destroy same or subject same to such treatment as will prevent the sale or use thereof for human food, and same shall be marked or tagged as condemned, and it shall be unlawful to remove the condemnation tag from condemned carcasses or parts of carcasses and offer said condemned meats as sound and wholesome, or to refuse to tank or properly dispose of condemned carcasses or parts of carcasses, or to remove same from tanks or other places in any manner not permitted, or otherwise fail or refuse to comply with the rules and regulations of said Bureau, and punishable by fine not to exceed one thousand dollars."

These I think are necessary to properly guard against the use of unwholesome and condemned meat.

(Reading:)

"4. In order to insure the inspection of all meat shipped in the interstate traffic, the Secretary of Agriculture should be authorized to make regulations prohibiting the shipment of uninspected meat from State to State or to foreign countries, in so far as he considers necessary to guard against the shipment of diseased products.

"5. It is desirable that the Secretary of Agriculture should be authorized to inspect and certify pure, high-grade dairy products for export. Our butter and cheese trade has been greatly damaged by the shipment of adulterated or low-grade butter and filled cheese branded as pure, high-grade products.

"6. Another point which is of some importance is that railroad companies, in the hands of receivers, are not held liable for violation of the law prohibiting the shipment of diseased animals from one State to another. This is a point which needs correction."

The present law says "owner or manager of any railroad company," and the Supreme Court held that that clause does not cover a receiver.

(Witness continued to read:)

"With these suggested changes, which are not very extensive, the Federal work for the assistance of the animal industry would be in excellent condition.

WHAT IS NEEDED IN STATE WORK.

"I thought of making an examination of the laws of the various States with regard to the control of diseases, but I find these exist in such number and are so voluminous that it is impossible for me to make an abstract of them. What I state, therefore, is my impression from what I have observed of the condition of affairs in various parts of the country.

"1. It appears to me that what is most needed in the way of State work is the thorough control and eradication of such diseases as glanders, tuberculosis, and

rabies. These diseases affect not only animals, but are communicable to man, causing in most cases fatal results. Trichinæ are found in American pork in a larger proportion than in most other countries. It appears to be due to the practice of allowing hogs to consume dead animals, such as rats, mice, and particularly hogs which have died of cholera. There is an impression in the hog-raising districts that the feeding of meat lessens the losses from cholera, and consequently if cholera outbreaks it is quite common to encourage the hogs to consume the carcasses of the animals which die. If there is only 1 in a bunch infected with trichinæ, this 1 is sufficient to infect the whole herd. The hogs which come to our markets are infected in the proportion of 2 per cent or more, and in some large lots of hogs we have found from 25 to 30 per cent with trichinæ. This matter is so important that there should be State laws prohibiting the feeding of the carcasses of dead animals to swine.

"2. The destruction of the Texas fever tick in the district permanently infected with that disease is of great importance. When this tick is killed out the infection disappears. It may be destroyed either by keeping cattle from any particular area for a year or two or by keeping the ticks all picked off the cattle or destroyed by various applications to the skin. It appears that the ticks must mature every year on cattle in order to perpetuate the species. In several counties of Virginia the ticks have disappeared through the effect of a law requiring cattle to be fenced in upon the premises where they are owned and prohibiting them from running at large. This matter is of great importance to the Southern States.

"3. Measures to insure the wholesomeness of the milk supply are also a matter of great importance. In cities and towns this matter usually comes under the health authorities, but it is seldom they have the money or the authority to inspect the stables and the cows from which the milk comes. As the contagion of numerous diseases may be carried in milk, and still other diseases and digestive derangements may result from contamination with filth and with various putrefactive bacteria, there should be some system which will insure clean stables, healthy cattle, and the proper handling of the milk. The increase of tuberculosis among dairy cows and the danger of conveying this disease to the consumer, and especially to children, emphasizes the importance of looking after the milk supply. This, it appears to me, could be most effectually done by a State board which applies uniform regulations to the dairies of the whole State. All measures enforced in this way should be well considered, conservative, and so formulated as not to be unduly burdensome to the cattle owners. Where it is necessary to eradicate a disease like tuberculosis, the owners of the cattle should be compensated for the animals condemned and destroyed.

"4. There should also be more efficient measures to guard the public from being imposed upon by impure, adulterated, or renovated butter and filled cheese. While these articles are not particularly dangerous to health, their sale as pure and high-grade goods injures the dairy industry and defrauds the consumer.

"5. There should also be a better local inspection of meats and more efficient measures to secure the proper disposition of the meat from diseased animals. While the Federal inspection is applied to all meats slaughtered in the abattoirs where it is established, the law permits the local sale of the condemned meat. The Department of Agriculture has endeavored to guard against this by making an agreement with the operators of the abattoirs that they will abide by the regulations of the Department which require the condemned meat to be made into products unfit for food. While this agreement is, so far as we know, carried out, with possibly a few rare exceptions, it nevertheless remains true that if such meat is removed from the packing house and sold locally there is no penalty in the Federal law for the punishment of those who are guilty. The natural effect of the Federal inspection is to drive the diseased animals to abattoirs which slaughter for local consumption, and consequently much more diseased meat is put upon the market in cities where the Federal inspection is in operation than was the case before this inspection was commenced. There are very few, if any, cities which have a sufficient force of competent meat inspectors to protect their citizens from diseased and unwholesome products.

"The vast influence of animal diseases upon the welfare of those engaged in agriculture, and, indeed, upon the country in general, is shown by the restrictions and prohibitions to which our foreign trade has been subjected on account of them. In 1879 our cattle were prohibited from going inland in Great Britain for sale, and were confined to a few docks called "foreign animal wharves," to be killed within 10 days, on account of the existence of contagious pleuro-pneumonia in this country at that time. This order is thought to have reduced the value of every American steer exported not less than \$5. As our exports have been from 100,000 to 400,000 head per annum since that time, the enormous aggregate loss is apparent.

"In 1881, or soon thereafter, nearly every country on the continent of Europe prohibited American pork for the alleged reason that it contained trichinae. This regulation was kept in force 10 years, ruining a great and growing trade and one which, despite our efforts, we have been able to only partially regain.

"Still later our sheep have been required to be slaughtered at the foreign animal wharves of Great Britain on account of the scab, which was continually breaking out among export animals because of their being exposed in the stock yards and cars of this country. Our live cattle and fresh beef have been excluded from Germany, Denmark, and Belgium, and our cattle from France, because of Texas fever in this country, which in rare instances was found in cattle landed on the other side. Our entire live animal trade with Great Britain was menaced because of the sufferings of animals in transit which shocked the humane people of that country. The legislation antagonistic to this trade appears to have been abandoned because of our action in establishing regulations for the humane treatment of animals during the ocean voyage. Our live swine are excluded from most European countries on account of cholera. Our canned beef has been excluded from Germany because of the detrimental statements, it is said, which were made during or soon after the war with Spain.

"In addition to these prohibitions and restrictions on the ground of disease, our export trade in butter and cheese with England has been greatly injured by the shipment of adulterated and renovated butter and filled cheese under representations that these were first-class dairy products. Canada, by supervising the manufacture and indorsing these goods, has established a great trade and won the markets away from our own exporters. Some of our best dairy products are now finding their way to Great Britain by way of Canada and branded as Canadian goods.

"Our farmers have suffered terrible ravages from disease, particularly hog cholera, sheep scab, and Texas fever, but as compared with European stock raisers they have little idea of the devastation on which animal plagues may cause. Such exotic and destructive plagues as rinderpest, foot-and-mouth disease, and pleuropneumonia have never spread over any considerable extent of this continent. Pleuro-pneumonia was introduced here, but never fairly reached the channels of commerce, and was fortunately stamped out before it did much direct damage. Foot-and-mouth disease has been introduced several times, but on every occasion was eradicated before it covered much territory. Rinderpest has never reached our shores. In other countries rinderpest has at times almost exterminated the bovine population, leaving but a few animals out of each thousand. Since the animal quarantines were placed under the Bureau of Animal Industry all of these exotic contagious diseases have been excluded.

"We have in our herds, however, tuberculosis, a disease which affects all warm-blooded animals, and which is also the most fatal of human diseases. While it at present affects but a small percentage of our animals, it is undoubtedly spreading and becoming more common, except in States where proper regulations are in force. Herds are frequently found containing 80 to 90 per cent of tuberculous animals, though the general average among dairy and breeding cattle is probably not over 5 per cent, and among beef cattle it is still less. There are more beef carcasses condemned for tuberculosis than for any other cause, the number being 4,194 for the last fiscal year. There were also 4,379 hog carcasses and 1,061 parts of carcasses condemned for the same disease. In some European countries nearly or quite half of the cattle are tuberculous."

Q. (By Mr. A. L. HARRIS.) How often or how many of these suggestions for Federal legislation have heretofore been made public, or gone to Congress in the way of suggestion for legislation?—A. Those penalty clauses were in the bill introduced 2 or 3 years ago, but I do not know if it got to the public further than the announcement that it was introduced and ordered printed. Those things do not usually go very far. The other points, I think, have not been given to the public. I intended to draft a bill and have it introduced at this session, but had so many other things to do that I have not done so.

Q. Have you any suggestions to make as to a better way to secure the enforcement of the State laws?—A. I do not know that I have. There are two difficulties in the States; one is to get money enough to do such things, and the other is to enforce the laws. While this is a Government by the people and for the benefit of the people, it is a fact that the nearer you get to the people the harder it is to enforce laws which bear upon the people in any section. Under the Federal law I can go into a State and do things easily which State authorities can not do at all, because the people in the State feel that the State authorities are subject to them more than the Federal authorities are, and if it is a case, for instance, of killing a glandered horse, the owner often will be ugly about it and will say, "I will not allow it to be killed," and very often the authorities are obliged to go

into court, or have trouble with the man. The same is true in enforcing other laws. We have an example of it in most cities in regard to rabies—mad dogs. When the city authorities adopt an ordinance requiring dogs to be muzzled and kept up a sufficient time to get rid of the disease, you always find a large number of citizens who object to the ordinance and say it is not necessary; that it is cruelty to the dogs, and so on, and it can not be enforced. We had the same thing in this city last winter. Although our Commissioners are not so much subject to the people as the officers of other cities are, yet the public clamor here prevented the enforcement of regulations requiring dogs to be muzzled, and as a result of that we have had rabies here since November a year ago. There has not been a month without rabies, and there has been—I forget just how many—but about thirty or forty people bitten in that time, most of them children, and they have been obliged to go off to other cities and take the Pasteur treatment, with an expense of a hundred or a hundred and fifty dollars for the treatment, board, and other expenses while away from home, which is a very serious matter to the people who are so unfortunate as to be bitten by a mad dog. The same principle holds good in the eradication of all diseases.

New York, which is one of our strongest States, undertook to eradicate pleuropneumonia. General Patrick at that time was business manager. They spent probably \$100,000, and then stopped because the work was not popular; they could not finish it. That was in 1879 and 1880. The work was dropped and the disease spread again, and when I took it up under the Bureau of Animal Industry, in about 1885 or 1886, there was just as much pleuro pneumonia in the State of New York as there was before they began. The same was true in New Jersey. The State authorities undertook to stamp out pleuro pneumonia there and failed. It is only in instances where the disease is not very widespread in the State, and where it can be done without very much expenditure of time or money, and without much hardship or inconvenience to the citizens, that the State authorities appear to be able to work efficiently in such matters.

Q. Have the States, as a rule, provided any compensation for destroyed animals?—A. Some of them have, and some have not. There is a great difference of procedure in the States, but the tendency is against compensation. The precedents among lawyers appear to be opposed to giving compensation for diseased animals. In the veterinary profession the tendency is to give compensation, because it has been found in all countries where they have tried to eradicate diseases that it was cheaper to give compensation, and have the stock owners with the authorities, than not to give compensation, and have it to the interest of everybody to conceal the contagious diseases.

Q. But could not the State authorities, for local diseases, such as glanders in horses, prevent the spread of disease more cheaply than to wait for Federal interference?—A. The Federal Government has not done anything in the way of stamping out any disease except pleuropneumonia and sheep scab. We never have gone into States, except in the pleuropneumonia work, and undertaken to condemn animals and kill them. It was then only in a great emergency, and we had the cooperation of the States to this extent: They made our men, in most cases, State inspectors as well as Federal inspectors, the expenses being borne by the Federal Government. Quite a number of States passed special acts making the Bureau of Animal Inspectors State inspectors, and giving them power to enter on premises, to inspect and condemn animals; but in those cases the States especially stipulated that it should be without expense to the State.

Q. Have you ever tabulated the figures giving the loss annually from the death of animals on account of infectious disease?—A. No. It is impossible to do it, because no one knows what animals die of. Our statistical division sometimes attempts to give a statement of the loss of animals from disease, but they are unable to discriminate between diseases.

Q. Would it be possible for the State authorities to provide some means for gathering that information?—A. It would probably be pretty expensive. In fact, I think it is impossible to get the information with any accuracy.

Q. (By Mr. FARQUHAR.) What State has the best regulation in respect to inspection of cattle and prevention of disease?—A. I think Pennsylvania, probably.

Q. They have a State board in Pennsylvania?—A. They have a State veterinarian there, who works under the Department of Agriculture.

Q. How much assistance has the State veterinarian in the practical work of the detection of disease?—A. I understand he has deputy inspectors who examine the cattle.

Q. In the State of Pennsylvania, for instance, how many?—A. Well, I could not say; but quite a number. They have spent a considerable amount of money—I am sorry I can't say exactly how much, but probably over \$30,000 annually—on tuberculosis work in the last few years.

Q. Do you know of any State where the inspection is so general and so well maintained that it is practically a remedy for the spread of disease?—A. For some diseases. There is no State, for instance, so far as I know, which has a sufficient inspection to prevent the spread of glanders in horses. It is a disease not looked after very thoroughly, and I suppose in every city of the country there is more or less of it. On the other hand, Texas fever is almost entirely prevented by cooperation between the Bureau of Animal Industry and the State authorities.

Q. Do you not depend a good deal on local help which comes entirely independent of the State veterinarian?—A. To a certain extent. We try and cooperate with the State inspectors, but usually meat inspection in the cities does not amount to very much, because the cities have not enough inspectors to control the local slaughterhouses. Almost every city has a large number of slaughterhouses in the suburbs, to which diseased stock goes for slaughter, and in order to inspect it thoroughly it would take as many inspectors as there are slaughterhouses, which, in a city like Philadelphia, would mean 75 or 100 inspectors. It costs a great deal of money to keep up such a force, and the only way in which to have practical inspection of an animal slaughtered for local consumption is to have the killing concentrated. Then they could have enough inspectors to cover it.

Q. How far does your national regulation covering the entire export trade affect local consumption?—A. It is impossible to say, because we inspect at all those large abattoirs which pretend to do interstate business, but a good many smaller places that do an interstate business we have not been able to cover. You can see from my statement we inspected 34,000,000 animals last year at the time of slaughter. That means about 5,000,000 cattle, 6,000,000 sheep, and the balance mostly hogs—23,000,000 to 24,000,000 hogs—and that, of course, covers by far the largest part of the meat. There are a great many small places where they kill 50 to 100 hogs a day, and 10 or 15 cows, where, so far, we have not been able to inspect, and I hardly see my way clear to include these. We have not so far been able to get enough inspectors.

Q. Has Congress been liberal with you?—A. Yes; very liberal.

Q. Any recommendation that the Department would make, would it readily meet with the cooperation of the Agricultural Committee?—A. I think it would, as far as furnishing money is concerned. They have given us all we could use to advantage, and sometimes I have turned back considerable into the Treasury. The number of cattle inspected at time of slaughter was 5,027,000. That is the great bulk of cattle slaughtered in the country. I suppose the entire slaughtering might be placed at 6,000,000 or 7,000,000 head in a year. The number of other animals inspected are as follows: Sheep, 6,125,095; hogs, 23,336,881; horses, 5,559. Congress put a clause in our appropriation bill 2 or 3 years ago to the effect that horses should be entitled to the same inspection as other animals. The reason for that provision was the low price of horses in the range country. In fact, there were some parties there who believed that they could slaughter horses to advantage for export, but I do not think they have done very well at it. They slaughtered the first year about 3,200, and the last year 5,559.

Q. (By Mr. A. L. HARRIS.) At how many points are horses slaughtered for export?—A. We have inspected at only one place, that is in Oregon. They have been slaughtering at several other points without Federal inspection. There was a place in Chicago, and there was a place in Brooklyn where they slaughtered.

Q. To what country does the horse meat go?—A. They sent some of it to Norway and some of it to Holland, but we are unable to follow beyond the ports where it lands. It is pretty hard to say where it is consumed. There have been some rumors that it had been made up in bologna and sent back here.

Q. (By Mr. FARQUHAR.) Do you find, in the establishment of these zones for the prevention of disease, that there is any conflict with the State authorities, or of late years have you met with cooperation with the local boards of health?—A. We have had pretty general cooperation. Of course, the State authorities do not always agree with us as to what ought to be done, but we generally get along harmoniously. The Texas-fever matter is one in which we need most cooperation now; Texas fever and sheep scab; both. The Texas-fever work is where there are more chances for difference of opinion, for always in States crossed by a quarantine line people below the quarantine line think they ought to be above it. It is more apt to be the case with Texas fever than with anything else, because the cattle below the quarantine line do not show the disease. It is only when they get out and mingle with northern cattle that they spread it.

Q. About your uniform procedure. Do you establish quarantine on State lines, or divide the State, if necessary?—A. We always make our quarantine line in the general regulations on State lines. Then in those States which are partly free from infection and which cooperate with us we put it across the territory of the State. Of course that is a great inducement for cooperation, because there is a

large part of the territory of these States which would be above the line, and which, without cooperation, would be below the line. I think probably that is the principal reason why we have so little disagreement with these State authorities.

Q. On account of the greater perfection in the rules of inspection and their administration, has the United States, your department especially, bettered the export trade or put it on a more sure footing?—A. We have saved the export trade in cattle. We would not have any export trade in live stock if it had not been for our regulations, because after the first step in confining American animals to the foreign animal wharves on the other side the agitation was very strong to entirely prohibit the trade in live animals. At the time our regulations for inspection of vessels were made there was a bill in Parliament, which appeared likely to pass, prohibiting carrying live animals. It was put on the grounds of cruelty to animals in transit and their arrival there in bad shape for slaughter; but when our regulations were made specifying how ships should be fitted up and how the cattle should be carried that legislation was dropped, and I have not heard anything about it since. The bill was being pushed by Mr. Plimsoll.

Q. Does the United States inspection stand equally with the foreign inspection in respect to meats, or, in other words, is it generally accepted by the foreign inspectors?—A. I can not say that it is. There has been no question in regard to it in Great Britain, where our largest market is; but in Germany they have not accepted our inspection, and most of our meat is inspected after it gets there. We did get our meat reentered in Germany by establishing our inspection and certifying to our meats, but still they continue to reinspect it.

Q. Was that really as a matter of conserving the public health, or was it a political matter on the agrarian line?—A. My own opinion is that it came from the agrarian agitation there.

Q. Have you inspectors on the other side?—A. We simply have three inspectors in Great Britain, two of them for the live animals—cattle and sheep—and one is now going to inspect the cattle coming from there.

Q. In the Department of Agriculture, especially in your department, have you the cooperation of similar bodies in the European governments, an understanding or a correspondence as to remedies and beneficial legislation?—A. No; we have none. We have, of course, more or less correspondence with the scientific investigators abroad; we hear of everything they do, and we cooperate by exchanging material for investigation more or less; but we have no cooperation in executive work.

Q. To what is the position of the agricultural societies of Europe in respect to American inspection and the importation of American cattle and American meats due? Is it to selfishness, or what?—A. It is mostly selfishness. It all comes from the agrarian agitation to keep out our products. We never have sent any diseases to Europe which appeared there among their stock. They know the nature of Texas fever, for instance, very well, because they have read our reports and they have confirmed our investigations by going over the same ground in their own laboratories; and yet they shut out not only our live cattle from Germany but our dressed beef, alleging it is from fear of this disease. There has never been a case of the disease there. In the same way in France they shut out our live cattle, following Germany, and Denmark and Belgium did the same thing. The two last-mentioned countries practically admit that they are unable to change unless Germany does, because if they let in our meat and cattle Germany would shut out theirs. So that Germany has been the leader in these provisions ever since the prohibition of our pork in 1881.

Q. Would you say that in the case of renovated butter, filled cheese, and imitations of standard butter Europe was justified in shutting them out by law or otherwise? In other words, do you think that our people here were at fault?—A. I think our people are at fault in shipping dairy products under false brands; but I do not know that they would be justified in shutting out the products entirely. I do not think they would; still I think they would be justified in making an inspection or in asking that we should make it.

Q. Would it not be fair for any foreign government to make the American article pay the cost of inspection when they detect fraud?—A. I should think it would. They make our meat exporters pay the meat inspection anyway in Germany and France. I believe that the Agricultural Committee is going to put a provision in the appropriation bill this year authorizing the inspection of dairy products and marking those which are pure and of high grade. Of course, we are not undertaking to mark everything or even to detect the spurious articles, but we will mark what we know to be first-class products.

Q. Would you advise that, in the case of milk inspection in cities and the local inspection of meats and all that, the penalties and the fines should be large enough to support a large force of inspectors; that is, that the violators of law should

pay for the inspection instead of the citizens out of the general treasury?—A. I doubt if they would get enough money in that way. It might be more practical to put a tax on all the meat that is inspected. Of course it is only occasionally that they are going to get a case of violation of the law which they can make hold in the courts. A man inspecting meats is morally certain of a great many cases where the handlers of meat violate the law for every one where he can get evidence to convict them of doing it.

Q. But in cases of local inspection where the fines are heavy the infractions of law are less, are they not?—A. They are where they enforce the fines. Usually when a fine is very heavy the tendency is to let a man off and not fine him at all rather than put a very severe penalty on him. I think where the fine is moderate the law is more apt to be enforced than where it is very heavy.

Q. We have in the Eastern States local laws providing that after the first conviction the fine shall be quadrupled. Is not that the way to reach the remedy?—A. I should think that would be a good plan.

Q. (By Mr. KENNEDY.) Have you ever had any knowledge or suspicion of your inspectors being tampered with by those interested in the work that they are inspecting?—A. Yes; we have. We brought a suit in one case; we brought an action against the manager of an abattoir in the West, and the judge decided on the constitutionality of the law, that we had no business to be inspecting. He decided the law to be unconstitutional, and as it was a criminal case it could not be appealed, so it rested. The point was this, that under the law, under the authority given to Congress to regulate commerce between the States, we could not go into a State and inspect this meat; that it did not become a subject of interstate commerce until it was actually in shipment from one State to another. It was one of those technical constitutional points which are raised sometimes. At any rate, the court refused to apply any penalties to those parties. There was good evidence that they had tried to bribe the inspector. We had changed inspectors three times. They had tried it first on one and then on another and then on a third one. They offered money to pass the meat, and then we thought we would bring an action against them.

Q. Did the money pass? Money was offered, you say?—A. Money was offered.

Q. And rejected and refused?—A. Yes.

Q. Why did you change the inspectors, then?—A. We wanted to make sure; we wanted to get more evidence. They might say in the case of one man, "We never offered that man anything; he was mistaken about what we meant; we did not intend to give him any money." But where three men come up and swear to the same thing the case would be much stronger.

Q. Have you a suspicion that that is pretty general in the abattoirs?—A. No; I do not think so. I think our inspectors are pretty honest and report any improper advances on the part of the abattoir managers. The only thing is, of course, it is human nature for a man after he has been in a place and gets acquainted with the abattoir authorities to try to draw the line so that he is lenient with them, and naturally if he is friendly with them he does not like to offend them by going further than they think he should go. That is the tendency; it is inevitable, and the only way we can counteract it is by changing the inspectors so that we can get new men there.

Q. You do that considerably, I suppose?—A. We do that whenever we think it is necessary.

Q. (By Mr. FARQUHAR.) Are all your employees under civil-service rules?—A. Practically all, yes; all of our inspectors and assistant inspectors, microscopists, stock examiners, and taggers.

Q. Are these microscopists and others subject to examination in Washington here, or are their qualifications passed upon in the State examinations?—A. They are examined in other States. The Civil Service Commission has an examination in all the large cities. They are appointed in Washington.

Q. Are they certified from the local list or from the national list?—A. The inspectors and assistant inspectors are certified from the national list, but the others are certified from the local lists. They are certified from different districts in the country so as to bring them closer to their homes.

Q. Is it a stable employment?—A. All of it except that of the microscopists. They do not have steady work; the work varies with the export trade. For instance, during the past year more than half the persons in the microscopical work have been on leave without pay simply because there was nothing for them to do.

Q. Has the establishment of your national bureau been an advantage to the science of veterinary surgery?—A. Yes; it has been an advantage to it by the investigation of quite a number of diseases that were not understood before. It

has been an advantage to it by furnishing employment for quite a number of men All the inspectors and assistant inspectors are veterinarians.

Q. And has it not also entered a good deal into the education in the agricultural colleges in the country, in the advancement of veterinary knowledge?—A. The demand for veterinarians, of course, has led to an effort to supply the demand by establishing veterinary departments in a good many of the colleges.

Q. Nearly all your inspectors or subinspectors or assistant inspectors are quite young men, are they not?—A. A majority of them are, because we appoint men at \$1,200 a year, and a man who is established in business could hardly afford to take it. Another thing, a young man fresh from college can pass an examination where a man who has been in practice for a while could not do as well.
